THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

VOLUME IX,

FROM MAY 13 TO NOVEMBER 11, 1882.

LONDON:
Printed and Published by JAMES GRAY, at the Office, 396, Strand, in the City and Liberty of Westminster.

1882.

Digitized by Google

250

19340

INDEX TO VOL. IX.

A

Abdank's Arc Lamp, 365.
Accidents by Lightning, 94, 155.
Accumulators (*see* BATTERIES).
Ader's Telephone, 390.
Africa, Proposed Cable on the West Coast of, 277.
Alexandria, The Telegraph and the Bombardment of, 204.
Allen's Electric Light Engines, 536, 537.
American Science Association, Montreal Meeting:—
  The Induction Balance, by Professor G. Bell, 417.
  Vision by the Light of the Electric Spark, by W. L. Stevens, 425.
  Nature of Comets, by B. H. H. Van der Weyde, 467.
  Secondary Batteries, by G. F. Barker, 467.
  Dangers from Lightning increased by Telegraph Wires, 467.
Ammeter, Description of, 373.
André's Arc Lamp, 138.
Anemometer, Bailey's Integrating, 117.
Atlantic Cables, ex-Stockholder's Circular Criticised, 85.
Atmospheric Electricity, by C. M. Smith, 471.
Ayrton and Perry's Measuring Instruments, 17, 373, 413.

B

"B. T. K." System of Electric Distribution, 560.
Barrett, Professor W. F., Alteration in Dimension of Metals Produced by Magnetisation, 519.
Batteries:—
  Bennett's Cell, 83.
  Influence of the Positive Electrode on Work of, 402.
  Kabath's Secondary, 61.
  Laurie's Cuprous Chloride, 54.
  Philippart *v.* Volckmar, 111.
  Relation between E.M.F.'s of Cells and their Chemical Affinities, by Dr. Wright, 162, 248.
  Secondary, by G. F. Barker, 467.
  Secondary, by Professor O. J. Lodge, 92, 130, 157, 207, 253, 522, 590.
  (*See* also under CORRESPONDENCE.)
Battery Current Tester, 30.
Belgium, Electro-Metallurgy in, 470.
Bell, Professor G., The Induction Balance for Detecting Metals in the Body, 417.
Bell's Telephone, 389, 538.
Berthoud and Borel's Cable Making Machine, 585.
Birmingham, Electric Light in (Gas Committee's Report), 571.
Birmingham Musical Festival, Electric Light at, 394, 491, 543.
Bjerkness, Prof., Hydro-Dynamic Analogies to Electricity, 162.
Blasting by Electricity, 111.
Bleaching Ground, Electric Railway in, 28.
Boat, Electric, "The Electricity," 496.
Books, Notices of (*see* REVIEWS).
Boom, Another (The Ferranti Machine), 516.
Bosanquet, R. H. M., Practical Electricity, 560, 591.
Brake, The Waldumer Electro Magnetic, 477.
Breguet, Antoine, Obituary Notice of, 227.
Brewtnall's Couplings for Wires, 30.
Bright, E. B., Gramme Machines, &c., 82.
British Electric Light Co.'s Search Light, 539.
British Electric Light Company's Exhibits at Crystal Palace, 82.
British Association, Southampton Meeting:—
  List of Papers to be Read, 323.
  Presidential Address, by Dr. Siemens, 342, 368, 372.
  Address to Mathematical Section, by Lord Rayleigh, 353.
  Abdank's Arc Lamp, by W. H. Preece, 365.

British Association (*continued*):
  System of Electric Distribution, by F. J. Sprague, 379.
  Recent Progress in Telephony, by W. H. Preece, 389.
  Report of Committee on Electrical Standards, 397.
  Edison's System of Electric Distribution, by F. J. Sprague, 403, 423.
  Electric Furnace, by Dr. C. W. Siemens and Professor Huntington, 418.
  Duration of Free Currents in a Conducting Cylinder, by Lord Rayleigh, 419.
  Report on the Ultra-Violet Spark Spectra Emitted by Metallic Elements, 425.
  Absolute Measurement of Currents, by Lord Rayleigh, 425.
  Equilibrium of Liquid-conducting Surfaces charged with Electricity, by Lord Rayleigh, 425, 496.
  On Some Apparatus for Use in Connection with Electric Light Measurement, by R. Sabine, 440.
  Contact Makers of Delicate Action, by Professor H. S. Hele Shaw, 442, 470.
  Sir Wm. Thomson's Potential Galvanometer, 447.
  Notes on Atmospheric Electricity, by C. M. Smith, 471.
  A Method of Investigating Magnetic Susceptibility, by Sir William Thomson, 478.
  The Thickness of Wire required to Carry Different Currents without Overheating, by Professor G. Forbes, 497.
  On a New Arc Lamp, by Professor G. Forbes, 497.
  Magnetical and Meteorological Weather, by Balfour Stewart, 501.
  Alteration in the Dimension of the Magnetic Metals produced by Magnetisation, by W. F. Barrett, 519.
Brooks's System of Insulation, 253.
Bürgin's Arc Lamp, 246.
Bürgin Dynamo, Trials with, 439.
Bürgin's Dynamo Electric Exploder, 303.
Burglars and Electric Alarums (Lead. Art.), 468.
Burglars Baulked, 503.
Burrell's Compound Engine, 271.

C

Cable, Central and South American, 11, 540.
Cable Protection, Congress on, 588.
Cable Repaired—Porthcurnow, Lisbon, 325.
Cable House Switch, Saunders & Kennelly's, 199.
Cable, Saunders's Translating Apparatus for, 151.
Cable Ships at Sea, Regulations for, 69, 181, 189.
Cable Testing, a Guide to Practice in, 445, 474, 493, 517, 541, 557, 604.
Cable on the West Coast of Africa, Proposed, 277.
Cable Work in Egypt, 610.
Cable Work under Difficulties (Suez Floating Station), 279.
Cables, Atlantic, ex-Stockholder's Circular Criticised, 85.
Cables, New, 162.
Cables, Protection of, 181, 189.
Camberwell, Specification for Electric Lighting in, 203.
Carbons for Incandescent Lamps:—
  Cruto's, 499.
  Müller's, 499.
Cardew, Lieut., Measuring Large Currents, 69.
Central and South American Cable, 11, 540.
Ceylon Telegraph Department, 30.
Chemical Affinity, Determination of, in Terms of E.M.F., by Dr. Alder Wright, 162, 248.
Chemical Substances under Magnetic Influence, Rotary Polarisation by, 254.
Chemistry of the Faure Accumulator, 612.
Chew, J., Electricity and Gas, 133.
Chronograph Engineers, 610.
Chrystal, Professor G., Abstract of his Lectures on Electricity, 221, 485.
Circuits, by F. C. Webb, 154, 298, 521.
City and Guilds Institute, Exam. Questions:—
  Electric Lighting & Power Transmission, 331.
  Electrical Instrument Making, 341.
  Electro-Metallurgy, 473.
  Telegraphy, 341.
City and Guilds Institute (Leading Article), 300.
Clausius, R., Electric and Magnetic Units, 149.
Clifton, Prof., his Electrostatic Apparatus, 136.
Comets, Their Nature, by B. H. H. Van der Weyde, 467.

COMPANIES MEETINGS, &c.:—
  (* Indicates Special Edition.)
  American Bell Telephone, 433.
  Anglo-American Brush Electric Light, 237, 285.
  Anglo-American Telegraph, 44, 248*, 308.
  Anglo-Austrian Brush Electric Light, 526.
  Australasian Electric Light, 94, 429.
  Birmingham and Warwickshire Brush Electric Light, 453, 502.
  Brazilian Submarine Telegraph, 20, 527, 596.
  Brush Midland Electric Light, 70, 140.
  Brush Electric Light of Scotland, 332, 358.
  Cuba Submarine Telegraph, 215, 239.
  Devon and Cornwall Brush Electric Light, 407.
  Direct Spanish Telegraph, 452, 502.
  Direct United States Telegraph, 44, 249*, 279, 563.
  Duplex Electric Light, 455.
  Eastern Electric Light, 563, 597.
  Eastern Telegraph, 179, 190, 212, 283.
  Eastern Extension Telegraph, 502, 563, 595.
  Edison's Indian and Colonial Electric Co., 454.
  Electric Carbon Storage, 332.
  Electric Light and Power Generator Co., 162.
  Electric Lighting Contract & Maintenance, 259.
  Electric Sun Lamp, 574.
  Faure Electric Accumulator, 42, 165, 614.
  Globe Telegraph and Trust, 250*, 281.
  Great Western Electric Light, 70, 117.
  Gülcher Electric Light, 382.
  Hammond Electric Light, 21.
  India Rubber, Gutta Percha, &c., Works Company, 260.
  Indian and Oriental Electrical Storage Co., 211.
  Indo-European Telegraph, 563.
  Jablochkoff Electric Light, 451, 502.
  London Platino-Brazilian Telegraph, 746.
  Maxim-Weston Electric Co., 162.
  Mediterranean Extension Telegraph, 383.
  Metropolitan Brush Electric Light, 234, 261.
  National Telephone, 358.
  Pilsen, Joel, and General Electric Light, 428.
  Provincial Brush Electric Light, 311, 359.
  Railway and Electric Appliances, 283.
  River Plate Telephone and Electric Light, 21.
  Rogers Electric Light, 597.
  South African Brush Electric Light, 141, 236.
  South Eastern Brush Electric Light, 310, 359.
  Submarine Telegraph, 282.
  Swan United Electric Light, 453.
  Telegraph Construction and Maintenance, 238, 563.
  United Telephone, 284.
  West Coast of America Telegraph, 571.
  West India and Panama Telegraph, 503, 569.
  Yorkshire Brush Electric Light, 430.

COMPANIES, NEW:—
  American Atlantic Cable, 146.
  Anglo-Austrian Brush Electric Light, 97.
  Anglo-Italian Brush Electric Light, 169.
  Anglo-Pacific Electric Light, Telephone, &c., 11.
  Anglo-Spanish Brush Electric Light, 123.
  Australasian Brush, 11.

Digitized by Google

COMPANIES NEW (*continued*):
Baltimore and Ohio Telegraph, 121.
Birmingham and Warwickshire Brush, 11.
British Indian Electric Light, 50.
British Insulite, 27.
Brush Electric Light of Ireland, 203.
Commercial Telegram Co. (American), 554.
Continental Electric Light, 50.
Devon and Cornwall Brush, 11.
Dominion Iron Company (Canada), Telegraph, Telephone, &c., 481.
Duplex Electric Light, 27.
Edison's Indian and Colonial, 97.
Electric Carbon Storage, 11.
Electric Sun Lamp, 169.
Electric Lighting Supply, 123.
Electrical Insulator, 218.
Electrical Share Trust, 74.
Electromotive Force, 506.
European, American, Canadian, and Asiatic Cable, 242.
Great North Western Telegraph (Canada), 193.
Henley's Electric Light, 74.
Jablochkoff Electric Light, 27.
Joel and Pilsen Electric Light, 2.
Laing Electric Light, 50.
London and Globe Telephone, 290.
Markland Electric Light, 123, 146.
Metropolitan Brush, 11.
Mexican Northern Telegraph and Telephone, 554.
National Secret Telephone, 1.
North Eastern Electric Light, 433.
Northern Mutual Telegraph and Telephone (American), 146.
Phœnix Electric Light, 11.
Pilsen, Joel, and General Electric Light, 11.
Provincial Brush, 11.
Railway and Electric Appliances, 11.
Self-Generating Electric Light, 50, 98.
Societe d'Eclairage Electrique (Paris), 170.
South African Brush, 11.
South Staffordshire Electric Light, 410.
Staffordshire and Worcestershire Brush, 11.
Standard Fyfe-Main Electric Light, 74.
Swan United Electric Light, 27.
Telephone Company of Ireland, 123.
United Kingdom Economic Electric Light, 123.
Yorkshire Brush, 27.

Competition for Posts in the Telegraph Service, 396.
Conduction, Electric, by F. E. Upton, 20.
Congress on Cable Protection (Leading Article), 588.
Contact Makers of Delicate Action, by Professor H. S. Hele Shaw, 442, 470.

CORRESPONDENCE :—
Accumulators (*see* BATTERIES).
Africa, Cable for West Coast of, 302.
Ammeter, Ayrton and Perry's, 500.
Ampere's Mnemonic Rule, 184.
Anglo-American Brush Corporation, 210.
Arc, Voltaic, Resistance of, 133.
Ayrton and Perry's Ammeter, 500.
Barrett, W. F., The Telephone Case, 133.
Batteries :—
Selion-Volckmar, 39.
Faure's, 39.
Secondary, E. Berliner, 39.
Secondary, W. Barton, 64.
Donnithorne's Secondary, 110.
Influence of Positive Electrode in, 423, 438.
Method of Charging Secondary, 586.
Ratio of Work to Weight of Lead Electrolytically Acted upon in, 469.
The Lane-Fox Patent and Electric Lighting, 557.
Berliner, E., Secondary Batteries, 39.
Bicycle, Electric Lights for, 358, 379.
Binko Electric Railway, 358.
Brain, W. B., Relation of Gravity to Electricity, 10.
Brewtnall, A. W., Binko Electric Railway, 358.
British Association Units, 500.
Brush and Gramme Machines, 39, 64.
Cable for West Coast of Africa, 301.
City and Guilds Institute, 328.
City and Guilds Examinations, 515, 538.
Crawley, C. W. S., Charging Secondary Batteries, 586.
Crompton Lamp, 88.
Crystal Palace, Notes at, 87, 110, 111.
Curative Electricity, 8, 40, 64, 110.
Currents, Mnemonic Rule for Remembering Direction of, 184.
Donovan, H. C., Curative Electricity, 40.
Du Moncel, Th., Telegraphing Without Wires, 438.
Duplex and Self-Generator Systems, 88.

CORRESPONDENCE (*continued*):
Dynamo and Magneto Machines :—
Brush and Gramme Patents, 39, 64.
Information Wanted by Revirsco, 557.
The Origin of the Current in, 301.
Letter from Wonderer and Answers, 210, 231, 249.
Dynamo, More Lines and Helical Force, 231.
Earth Movements and Earth Currents, 538.
East, Telegraphic Communication with, 302.
Edison or Swan, The Patent Question, 328.
Edison's System of Electric Distribution, 423.
Eggington, A., The Inductophone, 278.
Electric Lamp, Forbes' Arc Lamp, 514, 538.
Electric Lighting :—
Swan's System, 40.
and Gas, 231, 232.
at Glasgow Station, 587.
Fire Risks from, 249, 278, 302, 377.
in the City, 277.
and the Lane-Fox Patent, 557.
Electricity :—
Curative, 8, 40, 64.
its Relation to Gravity, 10.
What is It? 61, 85, 87, 109, 133, 155, 181, 183, 211, 232, 249, 326, 356, 393, 512.
Electric Railway, The Binko, 358.
Electric Units, Notation and Nomenclature, 232.
Electrode, Influence of the Positive, in a Battery, 423, 438.
Electromania, 301, 357.
Electro-Egoism, 328, 357.
Energy, Meter, 421.
Energy, Storage of, 9.
Engines, Kingdon's Compound, 422.
Fire Risks from Electric Lighting, 249, 278, 302, 377.
FitzGerald, D. G. :—
British Association Units, 500.
Curative Electricity, 64.
Ratio of Work to Weight of Lead Electrolytically Acted on in Secondary Batteries, 469.
Forbes' Arc Lamp, 514, 538.
Fox, Lane, His Patent and Electric Lighting, 557.
Fry, J. V., Telegraph Line without Insulators, 557.
Gas Engine, The Earliest, 557.
Gramme and Brush Machines, 39, 64.
Gravity, Its Relation to Electricity, 10.
Harbord, D., What is Electricity? 87, 133, 183, 249.
Heaviside, O., Dimensions of a Magnetic Pole, 63.
Hedges, K., Kingdon's Engine, 422.
Higgs, Paget :—
Electromania, 301.
Electro-Egoism, 328.
Hockin, C., The late, 65.
Horton, J., Electric Lighting at Glasgow, 587.
Hospitalier, E., Notation and Nomenclature, 232.
Humphrys, J., Electric Lighting in the City, 277.
India, Telegraphic Communication with, 302.
Inductophone, The, 278.
Jamieson, G., What is Electricity? 356.
Jewell, T. F., Resistance Regulator and Heating Apparatus, 587.
Johnstone, J., What is Electricity? 61, 109, 155, 232, 356.
Jones, C., Dynamo Machines and Helical Force, 231.
Kent, Charging Secondary Batteries, 609.
Kingdon's Engine, 422.
Kingzett, C. T., Influence of the Positive Electrode in a Battery, 423, 438.
Lachlan, W., Faure's Battery, 39.
Lamp Mania, The, 357.
Lane-Fox, Patent and Electric Lighting, 557.
Magnetic Pole, Dimensions of, 63.
Meter, An Energy, 421.
Meyer, H. R., System of Underground Wires, 379, 393, 423.
Milne, J., Earth Movements and Earth Currents, 538.
Mnemonic Rule for Direction of Currents, 184.
Moore, G. A., Notes at Crystal Palace, 87, 110.
Moseley, W., Fire Risks from Electric Lighting, 249, 302, 377.
Notation and Nomenclature, 232 (*see* also 204).
Offor, G., Electric Lighting and the Lane-Fox Patent, 557.
Phillips, J., Fire Risks from Electric Lighting, 278.
Postal Telegraph Department and City and Guilds Institute, 328.
Post Office Management, 514.
Probert, I., and A. W. Soward, Ayrton and Perry's Ammeter, 500.
Reckenzaun, A., Storage of Energy, 9.
Electrical Tricycles, 587.
Resistance Regulator and Heating Apparatus, 587, 609.

CORRESPONDENCE (*continued*):
Sayers, W. B., Dynamos, 231.
Scottish Brush Electric Light Company, 358.
Secondary Batteries (*see* BATTERIES).
Sellon, J. S., The Sellon-Volckmar Accumulators, 39.
Shakespear, J. D., What is Electricity, 211.
Shettle, Dr. R. C. :—
Curative Electricity, 8, 64, 110.
What is Electricity? 85, 110, 181, 326, 393, 512.
Sprague, F. J., Edison's System of Electric Distribution, 423.
Swan or Edison, the Patent Question, 323.
Swan's System of Electric Lighting, 40.
Telegraph Service, Inland, 209.
Telegraph Conference, The, 209.
Telegraph Line without Insulators, 557.
Telegraphic Communication with the East, 302.
Telegraphing without Wires, 438, 609.
Telephone Case, The, 133.
Thompson, S. P., Ampère's Mnemonic Rule, 184.
Tidal Wheel for Motive Power, 88.
Tricycles, Electrical, 587, 610.
United Telephone Company *v.* Harrison, Cox-Walker, and Co., 133.
Units, Notation and Nomenclature, 232.
Units, British Association, 500.
Voltaic Arc, Resistance of, 133.
Walker, S. F., and Olliver, Dynamos, 231.
Watt, A., The Earliest Gas Engine, 557.
Willan, F. L., Swan or Edison, 328.
Wires, Underground, Meyer's System, 379, 393, 423.
Wraight, Vincent A., Tidal Wheel for Motive Power, 88.
Wright, Arthur, An Energy Meter, 421.

Cosmical Induction, 500.
Couplings for Wires, Brewtnall's, 30.
Crompton-Bürgin Machine, Trials with, 439.
Crompton's New Arc Lamp, 585.
Crookes, W., Cost of Incandescent Lighting, 93.
Cruto's Carbon for Incandescent Lamps, 499.
Crystal Palace Exhibition (*see* EXHIBITIONS).
Cuprous Chloride Cell, by A. P. Laurie, 54.
Current Dynamometer, Sabine's, 441.
Current, Force, and Energy, by J. T. Sprague, 582.
Current Switches, 129.
Current Tester, 30.
Currents, Absolute Measurement of, by Lord Rayleigh, 425.
Currents, The Thickness of Wire Required to Carry Various Currents without Overheating, by Professor G. Forbes, 497.
Currents, Cardew's Method of Measuring Large, 69.
Currents, Duration of, in a Conducting Cylinder, by Lord Rayleigh, 419.
Cymapheus, Varley's, 494.

THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

No. 1.—Vol. IX. SATURDAY, MAY 20, 1882. Price 4d.

SLIP

Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ending April 21st amounted to £2,895

Electric Light in Mexico.—It is stated that the Mexican Chamber of Deputies has been lighted by means of electricity for some weeks past.

Electric Light in Vienna.—The Grand Café of the Residence, situated at the corner of the Franzensring and the Schottengasse in Vienna, is now lighted by electricity.

Electric Light for Kensington.—The Kensington Vestry have desired their Works Committee to consider whether it would be expedient to introduce the electric light into the parish.

Electric Light for Theatres.—It is proposed to use the electric light in the Philharmonic Theatre, Islington, which is to be reconstructed from the designs of Mr. Frank Matcham, architect.

South African Telegraphs.—The revenue receipts of the Cape Colony from telegraphs during March last amounted to £5,686, against £5,402 in the same month of 1881, being an increase of £284.

Charing-cross Electric Railway.—The Charing-cross and Waterloo Electric Railway Bill was considered on Friday week in the House of Commons, and read a third time on Tuesday, the 16th inst.

London-Platino Brazilian Telegraph Company.—The revenue of this company for the month of January, 1882, is estimated at £2,281 (Western Brazilian portion £1,517, land lines £764), as against £1,981 for the corresponding period of 1881.

Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ending April 21 were £1,767, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

Electric Light for Lewisham.—The surveyor to the District Board of Works for Lewisham having reported that the cost of the electric light would be greater than gas, the board have resolved to defer the question of its introduction into their parish for a time.

The Telephone Case.—This case is not yet concluded. The week has been spent chiefly in hearing counsel for the defence sum up the evidence on defendant's side, and the reply of the plaintiff's counsel. It is probable that judgment will not be given until next week.

New Telephone Company.—The National Secret Telephone Company has been incorporated at Albany, N.Y. Capital stock, 5,000,000 dols. The general route to be followed is stated to be from the city of New York to the city of Albany, and from there to the city of Buffalo.

The Sellon and Faure Battery.—The Faure Electric Accumulator Company commenced an action on the 10th inst. against the Electrical Power Storage Company, holding the patents of Messrs. Sellon, Volckmar, and Swan, in the High Court of Justice, for infringing the Faure Company's patent.

Electric Light in Italy.—The results from the use of Siemens's arc lamps in the railway station at Milan have been so good that the Minister of Public Works has decided to extend this system of lighting first to the other stations of the Upper Italian Railway, and afterwards to those of the central and southern lines.

Electric Light in New Orleans, America. — An American contemporary says that New Orleans has got its five miles of river front illuminated by 104 electric lights, and hopes to stop the pilfering of goods piled there, as well as to facilitate work, by this means. The city has in all over 300 lights of the kind in use.

Crystal Palace Exhibition.—As at present arranged, the Electrical Exhibition at the Crystal Palace will close on the 3rd of June. Already several exhibitors have begun the work of removing their goods. The Right Hon. the Speaker and a number of Members of both Houses of Parliament will visit the Exhibition on the 27th inst.

Electric Light in Brighton.—The Committee appointed by the Brighton Town Council to obtain prices for illuminating the front of the town, and the central valley as far north as the parish church, with electric light, for three years, have resolved not to proceed further with the negotiations until the Government Electric Light Bill has been finally settled by Parliament.

Society of Telegraph Engineers and of Electricians.—The next meeting of this society will be held at 25, Great George-street, S.W., on Thursday, the 25th May, when the following paper will be read by Lieutenant A. H. Bagnold, R.E., "The Organisation and Operation of the Field Telegraph Corps in the Transvaal, 1881, also some general remarks on Field Telegraphs."

Electric Light Bill.—The Select Committee on this Bill have been engaged during the week in taking the evidence of gas companies and corporations who supply gas, and corporations who do not. The proceedings consisted chiefly in the cross-examination of Mr. Farrer, secretary to the Board of Trade, by counsel representing the above bodies.

Digitized by Google

We shall refer to the proceedings of the Committee at greater length hereafter.

THE JOEL AND PILSEN LAMPS.—The prospectus has been issued of a company formed to work these lamps, under the title of "The 'Pilsen,' 'Joel,' and General Electric Light Company (Limited)." It has also acquired the patents for the "Gatehouse" incandescent light. The capital is £200,000, in 40,000 shares of £5 each, of which 12,000 shares are to be allotted as fully paid to the vendors, and the remaining 28,000 are offered to the public.

TELEPHONES WANTED.—The Guardians of the Salford Union, near Manchester, are inviting tenders for the erection and maintenance of telephonic communication between the several wards of the new hospital at Hope. Specification, &c., may be obtained of Mr. Booth, architect, of 88, King-street, Manchester. Tenders are to be sent to Mr: T. H. Bagshaw, Union Clerk, Union Offices, Eccles New-road, Salford, by the 25th inst., and they will be opened at the guardians' meeting on the 26th inst.

THE NEW ATLANTIC CABLE COMPANY.—Notices have at last been issued signifying that the American Telegraph and Cable Company's line to America is now open for public traffic, and that messages will be accepted at the company's stations, viz., 21, Royal Exchange, London, E.C., and A 5, Exchange-buildings, Liverpool. It will be seen from another note that the various cable companies have, as we hinted would be the case some time since, agreed to form a joint purse, and revert to the old rates.

ELECTRIC FIRE ALARMS.—In the annual report of Captain Shaw, chief of the Metropolitan Fire Brigade, it is pointed out that by reason of the system of electric fire alarms and the excellent telegraphic intercommunication between stations, &c., the various fire engines and men of the brigade can be concentrated on any given spot in a very much shorter time than was formerly the case. Captain Shaw reports that the electric fire alarm system has been found to work well, and it is to be greatly extended.

TELEGRAPHIC COMMUNICATION WITH GREENOCK.—As evidence of defective telegraphic accommodation at Greenock a local paper states that telegrams were despatched from Dublin, on the occasion of the Phœnix Park murders, to Greenock, asking the authorities there to keep a sharp look-out for suspicious characters; but as the telegraphic department of the Post Office in Greenock is closed from 10 p.m. on Saturdays till 8 a.m. on Sundays—and then only open for two hours—the Irish steamers had arrived hours before the office opened to receive the message.

ELECTRIC LIGHT IN THE OPERA, PARIS.—*La Lumière Electrique* says that it is a question whether the *foyer* of the Opera shall not be definitely lighted with the *Lampe Soleil.* Our contemporary quotes from a letter from M. Garnier, the architect of the Opera House, in which he says that he finds the lamp "absolutely perfect as regards steadiness and colour," and considers it as "the best light which can be employed for lighting works of art and picture galleries." According to this gentleman, the sole fault of the lamp is that is rather costly, but this consideration will not prevent its use in the Opera. We gave an illustration of the light as used in the *foyer* in our last issue.

ATLANTIC CABLE TARIFFS.—On the 13th inst. it was officially announced that a joint purse agreement had that day been executed between the Direct United States Cable Company (Limited), the Anglo-American Telegraph Company (Limited), La Compagnie Française du Télégraphe de Paris à New York, and the American Telegraph and Cable Company. Concurrently with this notice came the announcement that the rates to America and Canada are, on and after the 22nd May, to be again raised to two shillings per word. The Anglo-American Company notify a special rate of one shilling per word for Press messages, except for those forwarded between 6 a.m. and 12 noon, the rate for which will be sixpence per word.

ELECTRICALLY PROPELLED BOATS.—One of the features of the International Exhibition to be held in Turin, in 1884, will be a number of boats propelled by electrical energy. Signor Ivaldi, an engineer, Dr. Gasca, and Signors A. Marchi and Nigra, have asked permission from the Municipal Council of Turin to grant them a concession for the exclusive right to establish on the Po, between the windmills called Rocca and the new bridge, a service of boats propelled by electrical energy, supplied by means of special accumulators. They also request the gratuitous use during the exhibition of the hydraulic power of the river in the locality of the Rocca mills, where they will erect the motors for charging the accumulators.

THE FUTURE OF ELECTRIC LIGHTING.—On Wednesday, at the Royal United Service Institution, Mr. Spottiswoode, P.R.S., in the chair, Mr. St. George Lane-Fox read a paper on the above subject. Mr. Fox spoke of the great future before electricity, and dilated on the rapid strides that had been made of late years in its application to various uses. He described the incandescent lamp, which he thought would altogether supersede the arc lamp in a short period. With regard to the danger to human life from contact with wires carrying currents for lighting purposes, that he thought would be overcome by using low tension currents, which were harmless. And as regards fire risks, they could only arise from gross carelessness.

FIRE RISKS AND ELECTRIC LIGHTING.—The Society of Telegraph Engineers and of Electricians have appointed a committee to consider and report upon the rules which they would recommend for adoption for the prevention of fire risks arising from the use of the electric light. This committee is composed of the following gentlemen, viz:—Professor W. G. Adams, F.R.S.; Sir Charles T. Bright, Messrs. R. Crampton, R. E. Crompton, W. Crookes, F.R.S.; W. De la Rue, F.R.S; Professor G. C. Foster, F.R.S.; E. Graves, Professor W. E. Hughes, F.R.S.; W. H. Preece, F.R.S.; Alexander Siemens, C. E. Spagnoletti, A. Stroh, and Sir William Thomson, F.R.S. The first meeting of the committee was to have been held yesterday, the 19th instant, at 4:30 p.m.

ELECTRIC LIGHTING IN NEW YORK.—The contracts for lighting New York from the 1st of this month have been decided on. The United States Electric Light Company are to light the Battery Park, City Hall Park, Broadway from Canal-street to Fourteenth-street, Washington-square, and Fifth-avenue from Washington-square to Fourteenth-street with 65 lamps, at the rate of 70 cents per lamp per night. The Brush Company are to light Broadway and Fifth-avenue from Fourteenth-street to Thirty-fourth-street, Fourteenth-street from Fourth-avenue to Fifth-avenue, Thirty-fourth-street from Broadway to Fifth-avenue, and Union and Madison-squares with 61 lamps, at the same price, viz., 70 cents. per lamp per night. The other contracts for the remaining districts of the city were given to the gas companies.

COMMUNICATION BETWEEN ENGLAND AND FRANCE.—In the House of Commons on Monday Sir E. Watkin asked the

Digitized by Google

Postmaster-General whether the concession to the Submarine Telegraph Company for laying cables between England and France would bar the Post Office from assenting (with or without the concert of the French Government) to the laying of cables between the English coast and the Varne lightship, and the lighthouse on Cape Grisnez for the special purposes of enabling shore warnings to be given in cases of ships in distress in the Channel; and whether, if private persons were ready at their own cost to lay any such cables, he would give consent accordingly.—Mr. Fawcett, in reply, said that the concession held by the Submarine Telegraph Company did bar the Post Office from assenting to the laying of such cables as those referred to.

Electric Light in Milan.—The Café Biffi, in the Victor Emmanuel Gallery at Milan, is now regularly lighted by Edison incandescent lights, fifty-seven A lamps being used. The dynamo used to generate the current is the same as was lately employed when the *foyer* of the Scala Theatre was lit by Edison lamps for twenty-three nights, the machinery not having been removed. The Café Biffi is some 500 metres distant from the dynamo. The lights have been going for over a month now, and have given great satisfaction both to the proprietor of the café and the public. The arrangements were carried out by Mr. James Shepherd, agent for the Edison Company in Milan. We are informed that a company has been formed in that city to work Edison's patents, and that his lights will probably be shortly introduced into several public and private establishments.

A Submarine Telegraphic Entertainment.—Under the above title Mr. F. C. Webb, well known as having been intimately connected with the laying of many cables, announces that he will give a descriptive lecture on cable laying in St. George's Hall, Regent-street, on the 31st May at 2:30 p.m. The entertainment will consist of a *vivâ voce* explanation of the *modus operandi* of laying submarine cables, with some historical remarks, illustrated by coloured diagrams, on various ships that have taken part in cable-laying expeditions. It will conclude with a practical demonstration of how to make a splice, in which Mr. Webb will be assisted by men experienced in the work, he himself assuming the position, to which he is by no means unused, of "Engineer-in-Charge." Further information as to tickets, &c., can be had of Messrs. Mitchell and Son, 36, Parliament-street, S.W., or at the hall.

International Electrical Exhibition at Vienna.—On Thursday, the 11th inst., a meeting took place in the Bourse Buildings at Vienna (Baron Erlanger in the chair) to discuss the preliminary arrangements for the International Electrical Exhibition, which is to be held during the months of September and October. It was announced that the Minister of Commerce had sanctioned the use of the Rotunda (part of the Exhibition Buildings of 1873), and that both the Ministry of Commerce and the Ministry of War will be represented in the Exhibition. Official invitations are to be issued to all the foreign Governments; the export and import of exhibits will be free of duty, and the rights of inventors protected. Local committees are already formed in Germany, France, and Holland, and a number of leading firms from England, America, and Belgium have intimated their intention of joining in the Exhibition. The general committee consists at present of 73 members, and includes professors, electricians, editors, members of Parliament, financiers, and other influential parties. Out of the general committee a central committee was formed with 25 members.

Electrical Re-lighting of Miners' Lamps.—Messrs. Durant and Hubert have invented a method of re-lighting miners' safety lamps, extinguished by firedamp, without opening them, and without removing them from the explosive atmosphere. A practical demonstration of the system before the Société des Ingénieurs sortis de l'école d'Industrie et des Mines du Hainaut was regarded as satisfactory. Into the bottom of the lamp are fitted two plugs of wood, containing and insulating two copper wires, which are connected by a short platinum wire passing close to the wick. The ends of the wires are connected with the poles of a battery, so that on making contact the current raises the platinum wire to incandescence and lights the lamp. In order to prevent the production of sparks, on breaking contact, which would ignite the explosive mixture due to the presence of firedamp, the electrodes are kept clear of the fluid by means of spiral springs, and are only immersed in it by pressing the lamp upon them when it is to be lighted. The bichromate of potash battery has been selected, as being portable and, at the same time, powerful; and, to increase its energy, two zinc and four carbon plates are used. It is also proposed, eventually, to use a Daniell battery.

Consolidation of Electric Light Companies in America.—About a year ago the Gramme Electrical Company was formed by a combination of the leading companies owning patents for arc lights and machinery for generating electricity for such use. Recently the combination has been strengthened by union with the Edison Company, thus giving the Gramme Company control of all the leading systems of electric lighting. The combination now comprises the American Electric Company, the Brush Electric Company, the Edison Electric Light Company, the Fuller Electrical Company, the Jablochkoff Electric Lighting Company, the United States Electric Lighting Company, and the Weston Electric Lighting Company, in addition to the original company owning the Gramme patents. Before the last consolidation the Gramme Company controlled all the patents for working arc lights, and now it practically monopolises incandescent lighting also. The combination would appear to have been made chiefly to prevent litigation between the combining companies and to facilitate the suppression of organisations not in the ring by litigation, or competition, purchase, or otherwise.—*Scientific American.*

The "Retriever."—The following information is taken from the *Panama Star and Herald* of the 11th March last, and gives some information as to the movements of this cable ship, which is supplementary to that given by us some few weeks ago. Our contemporary says:—"The repairing steamer 'Retriever,' belonging to the West Coast of America Telegraph Company, under the command of Captain Morton, arrived in this bay early yesterday morning (Friday, March 10, 1882). She is at present engaged by the well-known submarine cable manufacturers, the India Rubber, Gutta Percha, and Telegraph Works Company, of Silvertown, London, to make the preliminary survey of soundings, &c., for the proposed extensive system of cables which this firm has undertaken to lay for the Central and South American Telegraph Company of New York. Mr. E. W. Parsoné is entrusted with this portion of the work, assisted by Mr. R. K. Gray, Mr. G. A. Darling (analytical chemist), and Mr. C. T. Hawkins (draughtsman). The 'Retriever' will leave at an early date to complete the survey between this port and Salinas Cruz, Mexico. Mr. Robert Kaye Gray may be expected to arrive on the Isthmus about the 22nd of this month. This gentleman has entire charge of this big undertaking, both at home and abroad."

The Telephone in Brazil.—According to to the *Anglo-*

Digitized by Google

Brazilian Times, the telephone was first introduced into Brazil in 1877. The first telephone was constructed at Rio de Janeiro, in the workshops of the Western and Brazilian Telegraph Company, under the direction of Mr. France. A short time afterwards, towards the end of 1877, Messrs. Rodde and Co. established a telephone line between their offices and the Rio Exchange. In 1879 the Telephone Company of Brazil, formed at Boston, obtained a concession for a telephonic line to Rio and Nitheroby; but, owing to delays due to the supineness of the Government, the company did not commence operations until the 28th May, 1881, with three lines of 1,500 metres long. From that time the extension of the system was so rapid that in ten months the company had constructed 600 kilometres of telephone lines in Rio and the provinces. At Rio de Janeiro also the company have eight telephone offices open to the public. The longest of the lines is 28 kilometres long. It is the precursor of one of longer extent—viz., one that will unite Rio to Pretropolis. In the interior of Brazil the planters make great use of telephone lines between the different portions of their plantations, other plantations, the railway stations, and the doctors' residences, &c. Several railway companies have also adopted the company's telephones.

The Atlantic Cable Companies.—An extraordinary general meeting of the Anglo-American Telegraph Company will be held at the Cannon-street Hotel, E.C., on the 25th May, at noon, to confirm and adopt an agreement made between this company, the Direct United States Cable Company (Limited), La Compagnie Française du Télégraphe de Paris à New York, and the American Telegraph and Cable Company, with respect to the division and appropriation of the joint traffic receipts. By this agreement, taken in connection with the existing agreements, the joint traffic receipts of the four companies will become divisible in the following proportions:—From the date at which the American Telegraph and Cable Company shall have one cable in complete working order and condition, and regularly opened for traffic, 55·125 per cent. to the Anglo Company, 18·375 per cent. to the Direct Company, 14·000 per cent. to the French Company, 12·500 per cent. to the American Company, and from the date at which the American Telegraph and Cable Company shall have two cables in good working order and condition, and regularly opened for traffic, the division of traffic receipts will be in the following proportions:—48·825 per cent. to the Anglo Company, 16·275 per cent. to the Direct Company, 12·400 per cent. to the French Company, 22·500 per cent. to the American Company. The above division of traffic receipts is subject to certain modifications in the event of interruption of the respective cables. An extraordinary general meeting of the Direct United States Cable Company will also be held at the same place, at 2 p.m., with the same object.

Magnetic Properties of Steel.—In a recent number of *Wiedemann's Beiblätter* the results of some experiments made by Herr Poloni to ascertain the permanent magnetic properties of steel at different temperatures were recorded. The rods under trial were cylindrical, and passed in a vertical direction through an induction coil. It was ascertained that, in order to assume the permanent magnetism corresponding to a certain temperature, the rod required a somewhat longer time for cooling than for heating. The greater the total decrease of the magnetism, the longer the time necessary. The number of successive heatings and coolings required to permanently magnetise the rod were nearly proportional to the permanent decrease of the initial magnetism. The greatest loss was between 170°—200°C. When the rod is hot every shock occasions a decrease in the magnetism, but after repeated agitations and heatings the rod undergoes no permanent changes. The distribution of the magnetism in long rods was likewise examined according to the methods of Van Rees. In his formula for the moment, M, at x points distant from the end, $M = a\,(1 + k^{-1} - k^{-x} - k^{(1-x)})\,x\,l$, where l denotes the length of rods and a and k are constants, it appeared that under certain circumstances k was constant at all temperatures for the same magnet, while a varied with the temperature. Below 180°C. the distribution of the magnetism was no longer variable, that is, the value of k remained constant, and the neutral line was always in the middle of the rods. Above 180°C. the same thing took place if the rod had been repeatedly heated before being magnetised. But if it had been magnetised before the heatings and coolings, k varied with the temperature, and the neutral line was displaced towards the north pole, so that austral magnetism extended over two-thirds of the rod.

The Telegraph in South Australia.—Alluding to the necessity for a transcontinental railway for Australia Mr. Thomas Harry writes as follows of the telegraph system in South Australia in a paper on that colony, recently read before the Royal Colonial Institute:—"Whenever," he says, "the work is carried out, its practicability will be much facilitated by the existence of that great work of which South Australia is so justly proud—namely, the Overland Telegraph. Immense as would be the benefits which a line of railway would confer in developing the resources of the Australian continent, it is doubtful whether they would exceed those which the centres of Australian trade and commerce enjoy as the result of the labours of those far-seeing men, Sir James Ferguson, Mr. H. B. T. Strangways, and others, who in spite of all opposition caused the telegraph to be taken across 2,000 miles of what were then pathless wilds, and brought the producers and factors of our leading Australian staples within speaking distance of the European markets. It has further served as the basis of all subsequent explorations, prevented the abandonment of the central country, and led to its gradual occupation for pastoral purposes. The main facts of the history of that enterprise are known to many of you, and are well set forth in Mr. Harcus's work on South Australia. It is five-and-twenty years since the desirability of connecting Australia with Europe by wire was first suggested, but the Colony was then too young to carry a scheme of such magnitude into practical effect. Five years later, on the return of Stuart, the explorer, from his adventurous journey right across the Continent, the idea was again revived, but it was not till 1870 that any practical steps were taken to execute the work. After some further delay, the first pole was planted at Port Darwin in September, 1870, but the whole line was not completed until August 22, 1872. Extraordinary difficulties presented themselves, but the work was successfully carried out under the able and energetic direction of Mr. Charles Todd, the Superintendent of Telegraphs. The length of the wire from Port Darwin to Adelaide is 1,916 miles. The total cost was about £450,000, the annual interest on which is by no means recouped by the receipts; but the indirect benefits to the Colony are immense. A member of the Legislature, who had opposed the Telegraph Bill, has since stated that within six months after the opening of the line the Colony netted nearly a quarter of a million sterling extra on their wheat harvest, through the telegraph enabling sales to be made in foreign markets, and facilitating the chartering of ships to convey the produce to Europe."

THEORY OF MAGNETO AND DYNAMO MACHINES.

XIII.

By means of this somewhat long preliminary we have got the ground pretty clear, and can now give the theory of the magnetic production of currents without much trouble.

But we warn the student that this part of the subject is not exactly after-dinner reading, and that he must make up his mind to work at it if he means to learn anything; and more especially we must warn him that all that has been written in the preceding articles will be supposed known, and will be quoted without special reference; so that he will do well to refresh his memory by reading connectedly the whole of those articles, paying *particular* attention to the following parts:—

Art. II., December 17, 1881.—All about lines of force and intensity of a magnetic field.

Art. III., December 24.—Behaviour of a circuit carrying a current in a magnetic field.

Art. IV., January 7, 1882.—Theorem at the beginning concerning the change in potential energy of a moving circuit, and the whole article.

Art. V., January 14.—First column.

Art. VI., January 21.—The whole, if the preceding articles have not been clear.

Art. XI., March 18.—Electromotive force, and energy of current.

Art. XII., April 1.—Ohm's and Joule's laws.

Work Done by a Revolving Coil.

Consider a circuit of area A, put in a uniform field of intensity I, with its plane along the lines of force (so that none of them pass through it); it experiences a couple, tending to turn it through a right angle, equal to γ A I; and the work it can do in turning through the right angle is also γ A I; in other words, it is equal to the strength of the current (supposed constant) multiplied by the total number of lines cut.

Rate at Which the Spinning Coil Does Work.

Let the rotation through the right angle take place in the time t, then the *average* rate at which the work is done is

$$\frac{\gamma A I}{t};$$

and by making t small, this quotient can be made large.

The *actual* rate, however, varies during the rotation; to find the actual rate in any position we must only rotate through a small angle $d\,\theta$.

Let the normal to the plane of the coil at any instant be inclined to the positive direction of the lines of force by an angle θ (the tendency being to make $\theta = 0$); the number of lines passing through the coils is

$$I A \cos\theta;$$

the change in this number for a small angular rotation, $-d\,\theta$, is

$$I A \sin\theta\, d\theta;$$

the work done is

$$\gamma I A \sin\theta\, d\theta;$$

and, if this be done in the time $d\,t$, the rate of doing work is

$$\gamma I A \sin\theta \frac{d\theta}{d t};$$

$\frac{d\theta}{dt}$ being the angular velocity, which we may hereafter style ϵ.

The Four Quadrants in the Rotation of a Spinning Coil.

The work done while the above coil is rotating from any position θ_1 to any other position θ_2 is simply

$$\gamma (N_2 - N_1);$$

that is,

$$\gamma I A (\cos\theta_2 - \cos\theta_1).$$

Starting from the position when all the lines go through "wrong way" ($\theta = 180°$), let it turn through a right angle, so that none go through at all ($\theta = 90°$); the work done in thus taking all the lines out is γ I A. Let it now go on turning through another right angle till all the lines are put through right way ($\theta = 0$); the work done is again γ I A, and has the same sign as before.

If you want the coil to turn any more you must drive it yourself, and must do work γ I A upon it for each of the next two quadrants of the rotation, viz., while you are taking all the lines out and putting them in wrong again, ready to begin afresh.

Loss of Potential Energy of a Moving Circuit.

The above is a special example of the general case, viz., that whenever a circuit conveying a current of strength γ is permitted to include N more "right" lines of force, it does work equal to γ N; and whenever it is forced to include N more "wrong" lines of force (or to lose N right ones), work must be done upon it equal to γ N. Since, however, it is not obvious where or against what this work is done, and since, in fact, this depends altogether upon circumstances, it is a clearer and indefeasible statement to say that the circuit loses potential energy γ N in the former case, and that it gains it in the latter.

For instance, whatever the potential energy of the revolving coil when all the lines go through it the right way, it is 2 γ A I units greater when they all go through it the wrong way. So that at every complete revolution from the latter position it loses γ A I units of energy in turning through each of the first two quadrants, and gains the same amount in the third and fourth quadrants.

Now where does this energy go to, and come from? If the rotation is resisted so that it turns quite slowly against friction, the energy lost will appear as external heat. If it is resisted by a spring, or a crank, or other mechanism, so as to turn quite slowly, the energy lost may appear as a bent spring, or raised weight, or other form of mechanical energy. If allowed to turn quickly against no external resistance whatever the energy appears as the kinetic energy of the moving circuit when it is flying past its equilibrium position and overshooting itself into the potential form again—like a pendulum. But in each case the mechanical energy is produced at the expense of the current, or rather of the battery which is supplying the current; hence either the current must be weakened by the motion, or the battery must be called upon to do extra work. The former is the case in quick motions, the latter in slow. But all this we must now investigate.

Case of a Stationary Circuit.

Let E be the E.M.F. of the battery, γ the strength of the current, and R the resistance of the whole circuit, then the energy of the current, or the work done by the battery in the short time $d\,t$, is

$$E \gamma\, d t.$$

A certain quantity of heat must be produced in the battery and rest of the circuit by the current, and the mechanical equivalent of this heat according to Joule's law is

$$R \gamma^2\, d t.$$

Now if no motion of the circuit or of magnets in its neighbourhood is allowed to take place, so that the number of lines of force passing through it is unaltered, there is no other form of energy but heat produced, and accordingly we must have

$$E \gamma\, d t - R \gamma^2\, d t = 0,$$

or,

$$R \gamma = E,$$

i.e., the electromotive force of the battery is the whole E.M.F. in the circuit.

This equation is no mere re-statement of Ohm's law. For, observe that R γ is the E.M.F. necessary to drive the current γ through the resistance R (by Ohm's law), and E means the E.M.F. of the battery; so when the equation asserts that R γ = E, it tells us the important fact that, in a circuit in which there is no motion with reference to the lines of force, there is no internal E.M.F.; but that the current is produced simply and solely by the external or "impressed" E.M.F. of the battery applied. [We are not here supposing that E is necessarily constant. The E.M.F. of even voltaic batteries depends somewhat upon the current

Digitized by Google

they are producing, the E.M.F. of dynamo machines depends enormously upon the current they are producing; but all we have said remains true for any kind of current generator, treated as an external E.M.F. applied to a circuit.]

Case of a Moving Circuit.

But now suppose that by reason of any small motion whatever the number of lines of force passing through the circuit (or the negative potential of the circuit) increases in the time $d\,t$, by the small amount $d\,\mathrm{N}$, so that the circuit loses energy equal to

$$\gamma\,d\,\mathrm{N},$$

what will happen?

The work done by the battery is, as before, $\mathrm{E}\,\gamma\,d\,t$, the heat generated, as before, is $\mathrm{R}\,\gamma^2\,d\,t$; but these two quantities do not exhaust the whole of the energy transaction, and they are no longer equal to one another; but

$$\mathrm{E}\,\gamma\,d\,t - \mathrm{R}\,\gamma^2\,d\,t = \gamma\,d\,\mathrm{N},$$

their difference equals the work done in the circuit itself.

This tells us, then, that

$$\mathrm{R}\,\gamma = \mathrm{E} - \frac{d\,\mathrm{N}}{d\,t}.$$

Now what does this mean?

$\mathrm{R}\,\gamma$ is by Ohm's law the total E.M.F acting in the circuit, but it is now no longer equal to the E.M.F. of the battery. The total E.M.F. is less than E by the amount $\frac{d\,\mathrm{N}}{d\,t}$, the rate at which lines of force are added to the circuit per second, or the rate at which the potential of the circuit is decreasing.

The difference between the applied E.M.F., E, and the resultant E.M.F., $\mathrm{R}\,\gamma$, must be of the nature of an opposition E.M.F., e—

$$\mathrm{E} - \mathrm{R}\,\gamma = e;$$

but by the above equation

$$\mathrm{E} - \mathrm{R}\,\gamma = \frac{d\,\mathrm{N}}{d\,t},$$

therefore, $\frac{d\,\mathrm{N}}{d\,t}$ is a measure of, and is numerically equal to, an opposition E.M.F. produced in the circuit as a result of the motion.

Putting it in another way. Applying Ohm's law to the circuit, we have no longer

$$\frac{\mathrm{E}}{\gamma} = \mathrm{R},$$

but

$$\frac{\mathrm{E} - \frac{d\,\mathrm{N}}{d\,t}}{\gamma} = \mathrm{R};$$

that is, the current is weaker than what the battery could produce in a stationary circuit: weaker not by reason of any increase in resistance, but by reason of an opposition E.M.F.

$$\frac{d\,\mathrm{N}}{d\,t}.$$

Now this is a most important result, because it shows how the phenomena of magnetic and current induction, discovered experimentally by Faraday in 1831, can be deduced theoretically by applying the principle of the conservation of energy to the electro-magnetic actions exerted between currents and magnets which were discovered and investigated by Œrsted and Ampère.

Sense of the Opposition E.M.F.

We have seen that when the circuit carrying a current is allowed to move as it wishes in a magnetic field—that is, when it moves so as to increase the number of lines of force passing through it in the right direction (the "right" direction meaning the same as that of the magnetic lines the current itself produces), or so as to decrease the number of lines passing in the wrong direction, in other words, so that the potential of the circuit decreases,* then the E.M.F. $\frac{d\,\mathrm{N}}{d\,t}$ is in opposition to the battery current which produces, or helps to produce, the motion. And the E.M.F., by thus weakening the battery current, does all it can to oppose the motion. This is Lenz's law.

* Remember that the potential energy of a current is $-\gamma\,\mathrm{N}$, not $\gamma\,\mathrm{N}$.

It is by no means essential that the whole motion shall be produced electrically. Suppose it is turned by hand in the same direction as the current would turn it, the same equation will apply exactly,

$$\mathrm{E}\,\gamma\,d\,t - \mathrm{R}\,\gamma^2\,d\,t = \gamma\,d\,\mathrm{N},$$

or

$$\mathrm{E} - \mathrm{R}\,\gamma = \frac{d\,\mathrm{N}}{d\,t};$$

but the opposition E.M.F., $\frac{d\,\mathrm{N}}{d\,t}$, may be now made very large by turning quickly—*i.e.*, by decreasing $d\,t$, and may equal the battery E.M.F. itself, in which case there will be no current for the instant; or it may overpower it, and drive a reverse current.

It is plain, then, that the battery force E is quite immaterial to the action, the induced or internal E.M.F., $\frac{d\,\mathrm{N}}{d\,t}$, developed by the motion, depending in no way on its value; hence the battery may be removed (the wires being joined up, of course), and the same equation will apply, with $\mathrm{E} = 0$. That is,

$$-\,\mathrm{R}\,\gamma = \frac{d\,\mathrm{N}}{d\,t}.$$

In this case the current, γ, is produced entirely by the motion; there is no other electromotive force acting at all. The motion in the magnetic field is by itself able to produce a current whose strength is numerically

$$\frac{\frac{d\,\mathrm{N}}{d\,t}}{\mathrm{R}};$$

and this induced current is always in such a direction as to oppose the motion.

DIP AND SPAN TABLES FOR TELEGRAPH WIRES.

BY R. VON FISCHER-TREUENFELD.

A telegraph wire suspended between two supports of equal height forms a curved line, "the catenary," depending upon the following conditions:—

S = span, or direct distance between the two supports.
l = actual length of wire between the two supports.
d = dip of wire.
W = weight of one foot of wire.
b = tension of wire at the lowest point of the curve.

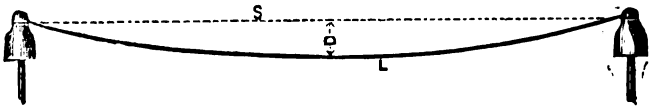
The mathematical deduction of these unknown quantities is to be found in many text-books of telegraphy, and the following equations only relate to the practical calculation of dip and span, viz.:—

(1) . . . . . $d = \dfrac{\mathrm{W}\,.\,\mathrm{S}^2}{8\,.\,b}.$

(2) . . . . . $l = \mathrm{S} + \dfrac{8\,.\,d^2}{3\,.\,\mathrm{S}}.$

(3) . . . . . $d = \sqrt{\dfrac{3\,\mathrm{S}\,(l - \mathrm{S})}{8}}.$

The following table and diagram are so arranged that the dip required for any span between 200 and 2,000 feet can be read off without calculation. A change in temperature



causes either an increase or decrease in the length (l) of the wire, the dip (d), and the tension (b). The table and diagram give the necessary allowance which must be made for any decrease of temperature after the day of the erection of any

given span. The wire must be erected under the following condition, viz., that after it has contracted to its minimum of length, under the action of the lowest temperature of the coldest winter day, the limit of tension (*b*), which represents a certain fraction of the breaking strain, must not be exceeded.

This fraction is generally one-third the actual breaking strain, and taking for illustration the P.O. standard wire, No. 8 B.W.G., of ·170-inch diameter, with a weight of 396lb. per statute mile, and 1,200lb. actual minimum breaking strain, the maximum tension (*b*) of the suspended wire, during its lowest winter temperature, ought not to exceed $b = 400$lb. The weight of 1 foot of this wire is $W = 0{\cdot}0751$lb.

The first vertical column of the table gives the spans or distances (S) between wire supports ranging from 200 to 2,000 feet; the second and third columns give the length (*l*) and dip (*d*) of the wire at one-third the actual breaking strain, with which the tension (*b*) is identical. These give the lengths and dips of wires when exposed to the lowest winter temperatures, and all other lengths (*l* at 10 degrees, *l* at 20 degrees) and dips (*d* at 10 degrees, *d* at 20 degrees), and running through 10, 20, 30, 40, and 50 degrees above the lowest probable temperatures of any climate, are calculated in such a manner that, after the wire contracts to its minimum length at the lowest winter temperatures, the tension (*b*) is exactly equal to one-third the actual breaking strain of the wire.

The co-efficient of expansion by heat for iron is $a = 0{\cdot}0000123$ for 1 degree Centigrade. The expansion is proportional to the length and also (within certain limits) to the increase of heat—that is to say, 10 millions of feet of iron wire expand 123 feet at each increase of 1 degree Centigrade. The increased lengths (l^1) of suspended wires are $l^1 = l\,(1 + a\,t)$, t representing the number of degrees Centigrade of increased temperature.

The vertical columns 4, 6, 8, 10, and 12 show these increased lengths of wires, after an increase of 10, 20, 30, 40, and 50 degrees Centigrade above the lowest winter temperature, and columns 5, 7, 9, 11, and 13 give the dips corresponding to these increased lengths of wires, and calculated by Formula No. 3.

The results of the table are graphically shown in the diagram, which, in order to render it applicable to all cases, gives the lengths and dips in feet and metres, and the temperatures in Centigrade, Reaumer, and Fahrenheit. The *modus operandi* is simple, it being only required to know

(1) The temperature during the erection of the wire.

(2) The lowest probable winter temperature of the locality where the wire is being erected.

Supposing it is required to erect a span of 800 feet in the South of England; the temperature of the day + 10 degrees Centigrade, lowest probable winter temperature − 5 degrees Centigrade; hence the wire would cool 15 degrees Centigrade from the day of erection to the coldest winter day. The ordinate of the diagram contains the degrees of increased heat over lowest winter temperature, and the abscissa shows the corresponding dips. Following the 15 degrees Centigrade vertical line in the diagram until it crosses the curve which represents 800 feet span, and projecting the crossing point towards the left edge the required dip can be read off = 16·5 feet. With this dip this particular span may cool 15 degrees Centigrade below the temperature at the time when it was erected, without the tension of the wire exceeding one-third the actual breaking strain.

Supposing this same span to be erected in England at a summer temperature of 20 degrees Centigrade, it would then be liable to cool 25 degrees Centigrade, and should be allowed a dip of 17·5 feet. If, on the other hand, the same span be erected at the same temperature in the North of Russia, viz., + 10 degrees Centigrade, and where − 25 degrees Centigrade would be the lowest winter temperature, the wire would then be exposed to 35 degrees Centigrade of cooling, and in this case the dip must be 18⅓ feet. Should it be erected in North Brazil at the same temperature of + 10 degrees Centigrade, the lowest probable temperature in that country being + 5 degrees Centigrade, the wire would only cool 5 degrees Centigrade, and the dip required would be only 15½ feet.

The dip of any given span in different countries, even when erected at the same temperature, depends upon the lowest probable temperature of that particular country. The non-observance of this fact either produces too much slack or causes the fracture of the wire during the coldest months of the year.

The table and diagram also show the proportion between dip and increased length of wire. A 200 feet span at its lowest temperature has a length of 200·012 feet, with a dip of 0·94 feet, or about 11·25 inches (see table, columns 1, 2, and 3). If this length be only increased one-tenth of a foot = 1⅕ of an inch, the dip increases from 0·94 feet to 2·90 feet, or from 11¼ inches to 34¾ inches (see columns 10 and 11), which means an actual increase of the dip equal to 23½ inches, or nearly twenty times as much as the increased length of the wire.

Digitized by Google

The proportion between dip and increased length of wire becomes less divergent with larger spans, thus:

The length of an 800 feet span at its lowest temperature is 800·750 feet, with a dip of 15 feet (see columns 1, 2, and 3). An increased length of one-tenth of an inch gives a dip of 15·95 feet (see columns 4 and 5), equal to an actual increase of dip of 11·5 inches, or only 9·5 times as much as the increased length of the wire span. From Formula (1), $d = \frac{W \cdot S^2}{8 \cdot b}$, it follows that the dip is practically the same for wires of different diameters, and of the same kind and quality. Hence the above table and diagram, calculated for a No. 8 B.W.G. wire (Post Office standard), will serve for iron telegraph wires of any size, although the results are only approximately correct.

*** The Table above referred to forms the Supplement to this week's *Electrician.*

CORRESPONDENCE.

CURATIVE ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In his letter to *The Electrician,* on April 29, Mr. Desmond FitzGerald says, "I make bold to assert directly and confidently that it has never yet been shown that magnetism—even as developed by the *most powerful permanent or electro-magnets—exerts any physiological action whatever.*"

This strong assertion is doubtless partially correct, but whilst admitting this much, I as confidently assert that every vital action is due to a display of that force which is known as the magnetic force; and that no other results than those named by Mr. Desmond FitzGerald could be expected from the clumsy and unscientific method which man has adopted to simulate the perfection of that mechanism which has been displayed by God in maintaining animal life.

Unquestionably physiology is the science which treats of the vital actions or functions performed by the organs of plants and animals. Natural and not exaggerated vital action must, therefore, be anticipated from the application of magnetism, if magnetism is the power which sustains vital action.

Prior to the evolution of any marked physiological action from the magnetic force, such as the spasmodic contractions of the muscles, &c., I am of opinion it would be essential that the force be converted into a current of considerable power, as in magneto-electricity. Then such phenomena would be readily elicited, and, in fact, I shall attempt to convince Mr. Desmond FitzGerald that all natural vital action is the direct outcome of magnetic power, and I am further of opinion that a knowledge of the principles of the mechanism by which vital action is maintained must afford much more reliable information as to the influence magnetism is capable of exerting in support of such vital action than the best attested cases, or the most powerful physiological action under its exhibition can supply. Nevertheless, beneficial results in cases in which it has been tried, and physiological action occurring under its influence, cannot be rejected as evidence favourable to its use. Under any circumstances the *absence of physiological* action can only be received as *negative evidence.*

As briefly as possible I will support the statement I have made that animal life is the immediate outcome of magnetic force.

1. The earth is a magnet.

2. Every form of matter has a certain capacity for this magnetic force of the earth, and the capacity varies with the molecular composition and other physical conditions of the matter.

3. Every form of matter transmits the force in lines which are characteristic of the matter. This law embraces the animate as well as the inanimate kingdoms of nature.

4. The first principles of magneto-electricity depend upon the recognition of the principle that when matter is moved through the lines of force emanating from a magnet, force is generated in the matter in a degree proportionate to the intensity of the magnetic force, the character of the matter, and the rapidity of the motion.

5. All animal life is accompanied with motion of matter, and this motion is molecular, probably atomic also. With but few exceptions, in the lower forms of animal life the moving matter is composed of a nutrient pabulum and a corpuscular portion. The latter, as shown by Dr. Gamgee, is highly magnetic both in the venous and arterial states. My paper in the *Proceedings of the Royal Society* (No. 157, 1875) proves that the arterial blood corpuscles contain more magnetic force than the corpuscles of the venous blood, a very important point, for the arterial blood sustains life, while the venous blood is incapable of doing so.

6. According to the physical laws referred to above it is impossible that the blood can move over the tissues in a state of health and through the lines of the magnetic force of the earth, which permeates every portion of those tissues, without originating in the tissues force, which must correspond in velocity with the force resulting from the motion of the magnetic power of the blood corpuscles.

7. When these tissues exist in continuous lines, as in the nerves, muscles, &c., currents of force must be generated, the rate of transmission of which must vary, other things being equal, inversely with the resistance each tissue offers to the transmission of force.

8. The nerve current or nerve power which regulates all the processes of life, mental and corporeal, is in exact proportion to the oxygenated and magnetic condition of the arterial blood; therefore, we can have no hesitation whatever in referring such nerve current to the motion of the magnetic blood corpuscles, in accordance with the principles of magneto-electricity.

9. By way of testifying to the influence which terrestial magnetism exerts upon the blood and tissues of the body, I may here mention that some years since I had a coil of wire constructed and so mounted upon a pivot that it could be rotated upon an axis at right angles to the direction of the strands of the wire when turned to any point of the compass. This coil is placed in connection with a very sensitive galvanometer, and the slightest motion upon its axis to the north or south gives a corresponding deflection of the galvanometer needle. The motion of the coil in this case gives motion to that quantity of the magnetism which it possesses in virtue of its being a portion of the mass of the earth, in a direction determined by the position of the wire relative to the lines of force, and the current is due and in proportion to the amount of mass displacement. This same law applies to magneto-electricity in general, and to *the mode in which the blood corpuscles originate force in the nerves and other tissues of the body.*

10. When artificial magnets are applied to the surface of the body, the terrestrial magnetic force passing through the body is increased in direct proportion to the power of the artificial magnets, just as the power of a permanent magnet is added to by each additional bar-magnet; but the tendency to general molecular motion must depend upon increase of molecular motion or force in the blood corpuscles, which act as the natural disturbers of that *equilibrium* of power which exists in the tissues owing to their connection with the earth's magnetism.

11. The degree of molecular motion will then be determined by the material composition of each molecule, and by this law there is reason to believe that a different description of molecular motion must take place in each form of animal life, *for as the blood corpuscles vary in shape in the different species of animal life, the particular description of motion by which they are formed must vary also.*

12. We thus further find that the primordial germ acts, as is generally supposed, as the directive agent of the force which maintains animal life, as a consequence of a *grand physical law which is common to all matter,* viz., *the directive influence which matter exerts upon force.*

13. This law may be distinctly traced from the atom to that combination of atoms existent in the blood corpuscles,

Digitized by Google

and then to the cells of animal life, which are formed, as I have already shown, under the influence of centripetal and centrifugal force; then onwards through the vegetable and mineral kingdoms of Nature to the mass of the earth itself, where we find it in operation giving the earth its particular inclination on its axis, by means of which its orbital motions, its seasons, and its mechanical life is maintained; from thence to the sun and so onward from centre to centre in the universe; each increasing in magnitude until it culminates in some vast centre from which it would appear all law, order, and power or force must emanate.

14. A great fundamental principle is evolved from these considerations of the relations existing between matter and force in animal life, which has an enormous bearing upon the mental and bodily health of the community, viz., that material purity is essential to the proper construction of every formation, and to the manifestation of that energy with which such formations are endowed. It will be found that this law holds good, not only with the ultimate atoms of matter, but with the simple or compound molecule, the blood or other cell, and manifests itself in the due performance of all the functions of life, not excepting the mental powers, with which man, as the highest form of created being, is endowed.

I trust Mr. Desmond FitzGerald, from a consideration of the facts I have thus brought very imperfectly before him, will perceive that I have good and substantial physical grounds for making use of magnetic appliances in the treatment of disorder and disease.

I could, however, refer to numerous cases which have been treated in hospital and private practice, some of which have been dealt with under magnetism alone, others, and by far the larger number, by magnetism combined with the usual remedies, in which great benefit, so far as I could determine, was derived from the use of magnetism.

My reference to cases in this letter can only be very brief. I will mention first my experience of the influence of magnetism as tried upon my own person.

Some few years since I suffered very severely from gouty dyspepsia; the attacks of gastrodynia and cardialgia usually coming on about two o'clock in the morning. It was my practice on such occasions to take a large teaspoonful of bicarbonate of potash, from which I usually obtained relief, but I have had to repeat the dose. Desiring to try the influence of magnetism I had a band made to go round my waist, the magnets being placed over the stomach, liver, and great solar plexus of nerves. Upon the next subsequent attack, instead of resorting to the alkali I put on the magnetic band as described, and within a few minutes all the usual discomfort had vanished. Upon every subsequent occasion of a like nature, and they have been numerous, I have found almost immediate relief from a magnetic band.

I have treated in the Royal Berkshire Hospital two very severe cases of scrofulous disease of the mesenteric glands in subjects somewhat advanced in life for such a disease. These cases resisted all remedies until the treatment was supplemented by the constant application of magnets. Then the remedies began to take effect, and the patients made very good recoveries.

I have also the records of cases of acute and chronic eczema which derived marked benefit from the application of magnetism.

I have been in the habit of advising many of my patients who are liable to periodical attacks of bronchitis to wear these magnetic appliances as prophylactics, and much benefit has resulted from their use.

If Mr. Desmond FitzGerald will place himself before a tolerably sensitive galvanometer and a magnet at his back and watch the effects upon the needle of the lines of force which pass through his body each time the poles of the magnet are reversed, I think he will admit that a magnet possesses a power which he had not realised when he expressed the opinion that magnets have not "any superiority over pieces of whalebone."

There appears to be some doubt in the mind of your correspondent with reference to my meaning in my allusion to the trade aspect of the matter under consideration. I would, consequently, further add that I have always regarded the question involved in the application of magnetism as a therapeutic agent, as affecting in the highest degree the best interests of man. I have, therefore, studiously avoided importing into the consideration of the subject any element whereby it might be imagined my judgment could be warped. In obtaining my magnetic appliances from the source named in my last letter on curative electricity, I have avoided any connection with those who were trading in them. I have thus, also, been able to regulate their power to the requirements of my patients, and, above all, I have completely eliminated that very seductive influence, pecuniary benefit, for I have refused, and still do so, to receive any percentage or other benefit accruing from their sale.—Yours, &c.,

Richard C. Shettle, M.D.

Reading, May 9th, 1882.

ON STORAGE OF ENERGY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The introduction of practically useful secondary batteries has set many schemes in circulation. Although few of the promises have up to this moment been fulfilled, the time seems near when the utmost use will be made of the advantages offered by these means of storing almost any form of energy. It is not my idea to propose a new scheme, because there is no novelty in the conception, but I have made it my purpose to collect such facts which might add to the general knowledge of the subject.

Visitors to the Paris Exhibition of 1878 no doubt remember the ingenious solar engine, or sun steam engine, invented by M. Mouchot, and I refer to this particular engine because it is the only one I ever saw in operation, although we are told that many attempts have been made to turn the sun's heat into motive power, from the time of Euclid and Archimedes to Ericsson, who published his researches on this subject in 1868 (see *Engineer*, Vol. 47). Without describing the apparatus, I will only state that M. Mouchot collects the rays of the sun by means of a large conical mirror, from the centre of which a tubular steam boiler projects, and the concentrated heat of the moderate Parisian solar rays at the end of September, 1878, produced a steam pressure of from 45 to 105lbs. per square inch, and the estimated power of this boiler was three horse-power. A small engine below the huge reflector received and utilised the steam generated. The great variation in steam pressure, and the fact that the reflector must always face the sun, necessitates a very careful management of the apparatus. Thus the utilisation of sun rays in this manner is not practical, apart from the mechanical difficulties which would have to be met with in constructing solar engines of larger power.

Since 1878 the world has been enriched by most remarkable improvements, and not least in importance were the Faure accumulator and Clamond's large thermopile, designed in 1879. Now instead of turning the sun's heat into steam power, by a judicious combination of these or similar inventions we ought to be able to convert them immediately into electrical energy. Clamond's thermo-electric battery of 3,000 iron and bismuth antimony pairs, with a difference of about 280°C. between the solderings, produces an E.M.F. of 109 volts, with a resistance of 15·5 ohms (*see* "Gordon," French edition). Another similar battery of 6,000 pairs has been used to maintain the electric lights of *two* (Serrin) arc lamps, with a consumption of 10 kilog. of coke per hour. This consumption of fuel cannot be considered economical compared with the amount of energy given off in the lamps, but if we could arrange thermo-electric pairs on a large surface, heated by the sun (in certain climates) or by the waste heat of our furnaces, and cooled by the earth, water, or air, an economical mode of transforming thermal energy might be obtainable.

The principal difficulty lies in the keeping of perfect contacts between the hot joints, or solderings, owing to the unequal expansion of the different metals; and another drawback to the efficiency of large thermopiles is the oxidation of surfaces.

At the Paris Electrical Exhibition I made a diligent search

Digitized by Google

after thermo-electric batteries, and found the following systems represented:—Bequerel, Clamond, Delaurier, Dubos, Gaulard, Melloni, Nobili, Noé, and Mr. Partz's, of Philadelphia, who placed a new battery in the Exhibition not many days before the same closed, without (to my knowledge) untying the brown paper in which the invention was wrapped. M. Sudre omitted to exhibit his inventions, and there are several English patentees of thermo-electric apparatus, but none was to be found at Paris, nor at the Crystal Palace, and I write this letter with the hope that experimentalists may be encouraged to come forward with the results of their researches for the benefit of science.

Apologising for my trespassing upon the valuable space of your excellent paper—Yours, &c.,

A. Reckenzaun, M.E.

Leytonstone, May 16, 1882.

THE RELATION OF GRAVITY TO ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Having read with great interest the letters by R. D. Shettle, M.D., on "What is Electricity?" it appears to me, from his last letter, that he will be able to demonstrate the relation of gravity to electricity. The subject is of great importance, and I wish him every success, and do not wish to detract from him the merit he deserves.

Having given a great portion of time to the investigation of magnetism and chemical force in the year 1876, to my mind the problem of the above-mentioned relationship was solved, but before making any statement I considered it prudent to find out if the penetrating researches of Faraday had not included this, and in Vol. III. of Faraday's works, page 161, is a description of the experiments this great discoverer carried out, and which dates July 19, 1850. He concludes with this statement:—"Here end my trials for the present. The results are negative. They do not shake my strong feeling of the existence of a relation between gravity and electricity, though they give no proof that such a relation exists."

Encouraged by this I ventured in a lecture delivered before the Bristol Mining Institute on February 24, 1877, to state my discovery. This lecture was afterwards published in the *Hereford Times*, and copied by some of the papers in the United States. Letts and Co. published it in the form of a small pamphlet.*

The method of demonstrating this truth that I selected was the formation of the diamond by decomposing carbon tetrachloride. The year 1878 was devoted to this purpose. My *success* in this direction made me more cautious and silent until the Scotch chemist (whose name I forget) demonstrated the formation of the diamond before the Royal Society, ill health having previously and since delayed my progress. But there appears to be no impossibility of producing a diamond from $\frac{3}{4}$in. to 1in. in thickness. I easily overcame the difficulty of obtaining the required high temperature, but the pressure not so easily, and the process requires courage with caution.

According to my method of demonstrating this truth, chlorine must be electro-negative as compared with oxygen, ("Correlation of Physical Forces," page 271), and potassium the same with lithium. The latter Dr. Paget Higgs informed me he had proved by experiment. The words used by Dr. Shettle, by which I saw he possessed the knowledge of what I had hitherto believed, or, perhaps, to speak more truthfully, vainly supposed was held by myself alone, are these:—"Then there must reside in the matter some force by which mass accumulation is affected, the removal of which must permit the expansion of the atoms, and of the mass as a whole." "This power must reside in the elementary atoms." "Then we are bound to admit that the atoms have been subject to a force which has compressed the atoms in a definite direction, and this direction must accord with the line of greatest density," and his next paragraph on crystallisation.

I have previously mentioned my attention to the formation of crystals (which has been a great help) which, with Plücker's inference with regard to the relation between the *forms* of the ultimate particles of matter and the magnetic forces, together with the idea of definite structure of the ultimate particles of matter as described by J. P. Cooke, the comparative weights and the comparative area of surface, as it relates to density, led to the same conclusion, viz., that the universe consists of matter and energy, that when energy takes the action of gravitation or cohesion electric energy passes from the matter acted upon, and by the removal of the force by which mass accumulation is affected electric energy passes to the matter acted upon. It is the difference or change of direction that determines whether we call it electric energy or gravitating energy. The sharp criticism which your correspondents display from week to week on such terms as potential, force, energy, &c., renders it difficult to express a term from which a great difference of opinion may not arise, especially when examined by the exacting mathematician.

Therefore, when considered as the same force, gravitation and electricity are terms which imply opposite direction; but when regarded as two forms of energy they are balancing forces or opposing forces, and it is admitted that "there is no known case of one form or part of a dual power existing otherwise than with and in dependence on the other, which then exists simultaneously to an equivalent, *i.e.*, an equal degree."

The theory of the æther assists the mind in comprehending the action of these physical lines of force, and the breaking up of masses of matter changing the lines of force into curved lines of force on the ultimate atoms. Showing the change from the static to the dynamic condition will require more space in your valuable paper than you will be disposed to give me this week, and the same remark applies to an explanation of magnetic action which can be demonstrated by the same laws, and which I have no doubt Dr. Shettle will also give us in his future letters.

Notwithstanding the strong impulse to believe the problem is solved, and the help I have derived from this theory during the past five years, I fully appreciate Faraday's words, "It is better to be aware or even to suspect we are wrong than to be unconsciously or easily led to accept an error as right," remembering that "the oretic conceptions are incessantly checked and corrected by the advance of knowledge."—Yours, &c.,

W. Blanch Brain.

St. Annals, Cinderford, April 19, 1882.

* A copy of the lecture referred to I send by this post for your inspection.

The Electric Light in Mull.—Several successful trials of the electric light have been made at Carsaig, the seat of A. J. Maclean, Esq., of Pennycross, in Scotland. The motor employed was a small turbine supplied by Messrs. Gilkes, of Middlesborough, to utilise the power of one of the many waterfalls which are to be found on Mr. Maclean's estate. The general result of the trials has been that with 25ft. of fall the water led on to a 7in. through $4\frac{1}{2}$in. piping supplied sufficient motive power when opened $\frac{7}{8}$, $1\frac{1}{8}$, $1\frac{1}{4}$, $1\frac{1}{2}$, and $2\frac{1}{2}$ inches, to light 1, 2, 3, 4, and 5 Swan lamps respectively; and at the last-named point to work one Brush arc lamp of 2,000 candle-power. This lamp placed on one of the crow-step gables of the farm-steading lighted the fields around for a distance of fully 200 yards with great brilliancy; and with a reflector, objects at much greater distance, such as the waterfalls on the hillside, sheep, &c., were made visible. On two successive evenings the incandescent lights did duty in-doors while the family were at dinner. The Swan lamps were lent by Messrs. Anderson and Munro, of Glasgow, and the other appliances, including Lane-Fox lamps, by the Brush Company of Scotland, through Mr. Mackie, their able manager in Leith. Mr. Maclean, we learn, was thoroughly satisfied with the light, and is taking early steps to have it permanently at Carsaig. The data of the trials have been carefully noted by Mr. Maclean, postmaster, of Oban, who, we believe, intends to publish them.

SOUTH AMERICAN CABLE WORK.

We have from time to time spoken of the manufacture, and of the ships used in laying a new cable for the Central and South American Telegraph Company. The cable has been manufactured by the India Rubber, Gutta Percha, &c., Company, at Silvertown, under the able superintendence of Mr.

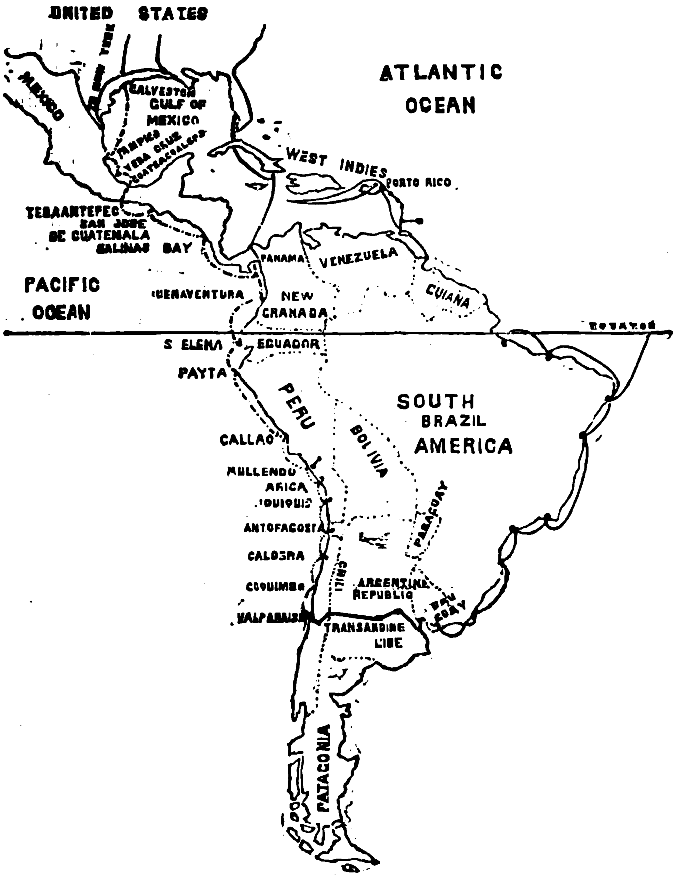

Fig. 4.—Sketch Map.

Gray. The contract was for more than 3,000 miles of cable, consisting of three types—shore end (Fig. 1), weighing 14·64 tons per mile; intermediate cable (Fig. 2), weighing 4·31 tons per mile, and main, or deep sea cable (Fig. 3), weighing 1·6 tons per mile. The breaking strain of the main cable is 5·5 tons. The sketch map (Fig. 4) shows the cable connections in South America as they will be when this line is completed.

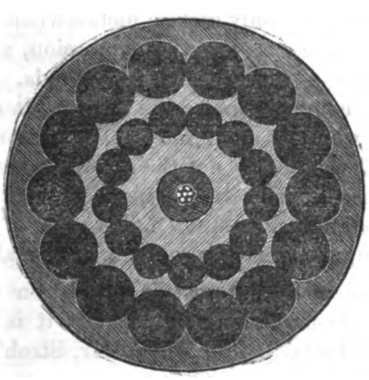

Fig. 1.—Shore End.

There will then be uninterrupted communication from North America *viâ* the Mexican Gulf to Valparaiso. It is hoped that the cable will be completed next month. The various station houses, 42ft. by 22ft., have, we believe, also been supplied by the Silvertown Company, as well as the whole electrical apparatus required, and the other fittings. The same firm has also supplied the materials for the land lines. We hope in a future number to describe the laying of these cables, as although it is stated that for the most part the cables will be in shallow water, and the work comparatively simple, there is always something to be learnt from such

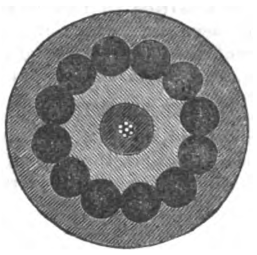

Fig. 2.—Intermediate.

operations. Mr. J. B. Stearns, the South American Telegraph Company's chief engineer, has certified that the whole cable is in all respects in accordance with the contract specifications. We had the pleasure of witnessing the manufac-

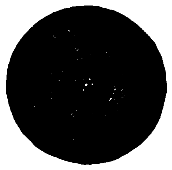

Fig. 3.—Deep Sea.

ture of some portion of this cable, and we cannot but congratulate Mr. Gray upon the excellent manner in which the manufacture, shipment, and, so far, the laying operations, have been carried out.

New Companies.—Within the past few days the following electric light companies have been floated, viz.:—The Birmingham and Warwickshire (Brush) Electric Light and Power Company, with a capital of £100,000; the Metropolitan (Brush) Electric Light Company, with a capital of £1,000,000; the Provincial (Brush) Electric Light and Power Company, with a capital of £200,000; the Devon and Cornwall (Brush) Electric Light and Power Company, with a capital of £100,000; South African (Brush) Electric Light and Power Company, with a capital of £100,000; the Australasian (Brush) Electric Light, Power, and Storage Company, with a capital of £255,000; and the Staffordshire and Worcestershire (Brush) Electric Light and Power Company, with a capital of £200,000. The Phœnix Electric Light and Power Company, with a capital of £250,000, has been started to work Mr. FitzGerald's lamps and dynamo machine. The Anglo-Pacific Electric Light, Telephone, and Power Company has been started to work the respective electric light and telephone systems of the Brush Company, Professor Dolbear, Mr. Edison, Professor Graham Bell and others, with a capital of £300,000, on the West Coast of America. The Pilsen, Joel, and General Electric Light Company has been formed with a capital of £200,000; as also have the Railway and Electric Appliances Company, capital £500,000, and the Electric Carbon Storage and Apparatus Manufacturing Company, capital £150,000. The daily papers have recorded in varied language this sudden flood of companies, but the majority of them stigmatise it as a "mania," and prophesy that some one will be "bitten." The *Daily News* of the 18th inst. says:—"Opinions differ of course, some being that the general inevitable collapse has begun; others that, this being an opportunity for the public to come in, the bears will be caught, and a great reaction will ensue." It does not appear either that we have yet come to the end of this formation of new companies, as we have heard of more than one concern which it is intended to float in the immediate future.

MR. STROH ON SONOROUS VIBRATIONS AND MAGNETISM.

We last week completed our account of Mr. Stroh's lecture, and before these lines are in the readers' hands its re-delivery will have taken place to a largely augmented audience. The interest which the subject of Mr. Stroh's experimental researches had already awakened insured an unusual attendance on the first occasion of their publication three weeks ago, but we have little doubt the council of the Society of Telegraph Engineers will have been justified in their prediction that a larger and more influential attendance would welcome Mr. Stroh's re-appearance. A rehearing was the more needful because, as we stated in our account of the original proceedings, nothing short of personal witness of the experiments would insure full justice being done to them. We are only repeating what was frankly admitted at the time that Mr. Stroh proved himself not only the careful experimenter and wonderful mechanician which we all knew him to be, but the possessor also of that rare gift of making oneself thoroughly well understood. As one well-known professor remarked it was not Mr. Stroh's business to lecture, but his performance that evening made all professional lecturers envy him. If he is as successful both in manner and matter as he was on the first occasion, Mr. Stroh's fresh audience will by this time be congratulating themselves on having had an altogether exceptional treat in the way of scientific exposition.

From one point of view Mr. Stroh's revelations were not, perhaps, of immediate consequence, but from another point of view their prospective importance can hardly be exaggerated. No thoughtful person could fail to see that a new means of investigating the phenomena of magnetism was now available, nor avoid speculating on the momentous disclosures which then for the first time seemed near at hand. That magnetic forces act in the same manner and in the same lines as do the forces set up by vibration is a fact not of striking moment, except as a new example of the uniformity of natural laws; but when it is realised that we have now for the first time discovered a way of not merely identifying, but of tracing those laws to their very source, so to speak, Mr. Stroh's experiments become extremely significant. For centuries we have "known" the magnet; only lately have we found out what it would do for us; and now at length we seem to be on the eve of learning the *how.* Until we listened to Mr. Stroh we had given the magnet up as an inexplicable mystery —a something to be used but not to be explained. The most learned exponent of the properties of magnetism was brought to pause if a simple schoolboy asked him, How comes it so? The schoolboy cannot be answered even yet, but one feels that the answer is not nearly so far away as it was but a few short weeks ago.

Mr. Stroh's experiments originated with those of Dr. Bjerkness, which were exhibited at Paris last year. Interesting as were those singular examples of attraction and repulsion in the case of vibrating drums under water, probably very few who witnessed them thought of them as anything but a curious parody of magnetic phenomena. Mr. Stroh appears to have taken a more serious view of them, and he determined to satisfy himself whether the seeming resemblance was real. This, of course, is not proven—perhaps is not capable of proof—but their identity of action he has demonstrated in every detail. Even where the operation seemed to be inverse to that of magnetism—as in the case of diaphragms vibrating in like and unlike phases—the seeming contradiction proved to be only verbal, attraction and repulsion actually occurring just as we know they do occur in the case of similar or dissimilar magnetic poles. But this is not all. We knew that vibration, even that impalpable vibration which gives voice to the telephone, indicates motion which imparts itself mechanically to the surrounding air; we knew also that light bodies assumed geometrical patterns when placed on a vibrating plate; what we did not know was that these air movements, these strange figures, corresponded exactly with the lines of magnetic force, and when diagramatically represented were the same as the old familiar pictures of the magnetic "field." The force is mechanical in the one case, and is what we must continue to call magnetic in the other, light bodies of any material being attracted or repelled when the force is vibratory, and only certain metals when it is magnetic; but the *habit,* if we may use the expression, is the same in both, and both pursue the same methods. The question then arises, Are not the forces the same? It is an important question, but whether answered in the affirmative or not—that is to say, whether or not the action of magnetism prove to be a species of vibration—the fact that vibration is a species of magnetism cannot fail to be a valuable help towards finding out what magnetism itself really is.

For the moment all interest is centred on the relation of sonorous vibrations to magnetism; but it is safe to conjecture that the investigation which Mr. Stroh's experiments have, doubtless, given rise to in many quarters will not stop at this. Not less mysterious than magnetism is the phenomenon of electricity, and thoughts fixed on the cognate properties of the magnet are pretty sure to be speedily turned to the phenomena of electro-magnetism. It would not surprise us if Mr. Stroh has already been tempted into this line of investigation. We would not presume to anticipate anything he may have to disclose on the subject,

Digitized by Google

for we are sure that nobody in this country is better able than himself to examine it as it deserves to be examined. Our meaning will be obvious to every electrician. There is a magnetic field about every electric current, and, therefore, about every conducting wire. What we should like to know is whether this electro-magnetic field, in the case of a conducting wire, can be imitated in the case of a vibrating wire. It is certain that the attraction, and, possibly, the repulsion, of light bodies can be obtained even by the vibration of a fiddle string; but the identity of direction as compared with the known direction of magnetic force surrounding an electric conducting wire is still uncertain. The lecturer of last Thursday evening is just the man to determine this point for electrical science once and for all. Delicate and tedious as would obviously be the experiments necessary to establish the identity here suggested, the results would be well worth the pains. To solve the mystery of magnetism would be a remarkable feat, but to contribute something towards the solution of, if possible, the still greater mystery of electricity and its mode of travelling would be a feat worthy even of Mr. Stroh, and that, indeed, is saying a great deal.

SPECULATION.

We have no wish to decry the Englishman's privilege to grumble, but rather to act the part ourselves. It may be that promoters will not like our grumbling. That, however, is of no great matter, especially if, on the other hand, words of caution may induce some people, who have money but no brains, to save their money from the harpies, who have brains, and would like to have money. The existing state of things with regard to electric light companies is deplorable. Company after company is promoted and floated with a huge capital when it is absolutely certain that for years to come there will not be legitimate business enough to pay any per centage on a large part of the capital subscribed. These companies are, for the most part, intended to supply the electric light, and, startling though it may be, let us say once for all that there is no single company existing, so far as we are aware, that has yet made a dividend from its electric lighting work. This speculative gambling is a curse to true enterprise. Rotten companies, not worth the paper their prospectuses are printed on, are always started when the public lose their heads, as they seem to have done now, to the loss of the ultimate holders of shares. Companies may be and are brought out legitimately, and are worked by honest men. Unfortunately the public will not discriminate, and instead of taking counsel of their natural advisers, the scientific press, in such matters as electric lighting, prefer the probability of "heads" turning up in the gamble.

We are glad to see that for once the political press is speaking somewhat plainly, although in some of the money articles, so great is the "trimming" that what is intended as a caution to those who can read between the lines is openly advertised as an incentive to investors. The *Pall Mall Gazette*, in its City Notes of Tuesday last, had among other paragraphs the following, which is worthy of close attention :—" As the speculation has now reached a height so prodigious that the shares of one company alone—the Anglo-American Brush Light Company, of the original value of £400,000, including £100,000 in fully paid up shares paid as part of the purchase-money to the Anglo-American Electric Light Company—are now worth in the market more than £1,500,000, a few facts regarding the development of the gamble will be interesting, and possibly useful, to outsiders apt to be drawn in by the sight of the apparent gains now being pocketed. Including the South African Company, issued on Saturday with a modest capital of £100,000, the Brush Light Company or its offshoots has created nine subsidiary companies, to which it has sold the "rights" attached to its patents in the provinces or in various places abroad. Or rather the Brush Light Company has first sold concessions to individuals, and these in turn have formed new companies in a manner that has been highly profitable to all concerned—except, possibly, the ultimate finders of the cash. We have examined their prospectuses for particulars regarding the prices paid by the shareholders to the 'vendors' of these tributory companies, and have noted also where possible the cash said to have been paid by these vendors to the parent company for their concessions. As a rule, the latter fact is not stated, but without that the result is very instructive. Altogether, £205,000 in cash and £178,000 in shares have in this way been paid by these companies to the vendors, in the manner exhibited by the following table:—

Name of Company.	Capital issued.	Cash Paid to Vendor.	Amount in shares to Vendor.	Portion of Cash to Brush Co.
Electric Light and Power Company of Scotland (Brush)........................	£150,000	£15,000	£40,000	not stated
South - Eastern Electric Light and Power (Brush)	100,000	12,750	2,000	£10,000
Midland Electric Light and Power (Brush)	125,000	25,750	18,000	
Provincial Electric Light and Power (Brush)	100,000	30,000		25,000
Australian Electric Light, Power, and Storage Company (Brush)	155,000	45,000	30,000*	not stated
South African Electric Light and Power (Brush)	100,000	25,000		
Eastern Electric..............		32,000	38,000	not stated
Hammond	125,000		35,000†	not stated
Great Western	125,000	19,500	15,000	£12,750

* 1,000 founders' shares in addition. † 20 founders' shares in addition.

This is exclusive of the Devon and Cornwall Company, which is an offshoot of the Great Western Company, and of whose capital of £100,000 £34,750 goes to vendors and patentholders."

THE INDUCTOPHONE.

Mr. Willoughby Smith, so well known to most of us as an able experimentalist, has been recently experimenting in a direction that promises to be very fruitful of interesting and valuable results. We hope in our next issue to illustrate Mr. Smith's apparatus. In the meantime we may say that, using a tuning fork as a make and break contact in circuit with a large flat disc of insulated wire, he finds that a telephone, or a Bell telephone without the coil, or a magnet, or a piece of iron, altogether unconnected with the circuit, will reproduce the musical sound of the tuning fork. By means of a diaphragm he has investigated the lines of force from the coil, and has obtained some interesting results. The sounds are reproduced if the receiving diaphragm is in another room, or if there are two rooms with their walls and air between. In fact, the lines of force seem to extend a long way. If the diaphragm is placed parallel to the lines of force no result is obtained; but, of course, this may be obviated by using a hollow cylindrical or polysided diaphragm with a suitable magnet. Mr. Smith has undoubtedly shown us how to investigate in a new direction which promises well. We ourselves have made a number of experiments in this direction, with very satisfactory results.

THE CRYSTAL PALACE EXHIBITION.

The Swan Light.

Before entering upon the special subject of this paper we may call attention to the fact that almost without exception the various lecturers at the Palace on Wednesday evenings have dealt somewhat in prophecies. Not only is the electric light to be *the* light of the future, but electricity is to be the transmitter of power of the future. Mr. Edison is designing his central stations with a view to supply power as well as light, and he hopes by this means to get the greatest possible per centage of work out of his machinery. It will be seen that Mr. Bright in his lecture touched on the same subject as did Mr. Crompton. More than forty years ago attempts were made to utilise electricity as a transmitter of power as well as directly as a motor. In 1836, Mr. Davenport, then a blacksmith in Philadelphia, turned lathes by means of electricity. In 1838, Professor Jacobi used a battery to propel

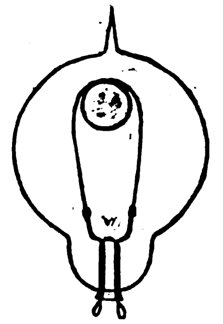

FIG. 1.—Swan's Lamp.

a boat on the Neva. In 1839, Mr. Robert Davidson used electricity to drive a carriage, and so on. We see, then, that the idea is in one shape by no means new. In a number of the *Practical Mechanic*, published in November, 1842, we read:—"So far as trials have been made, the hope is not excluded that this new agent may yet become a powerful rival to steam. In point of safety its superiority is unquestionable; but it remains to be determined whether or not sufficient power can be obtained on equally economical conditions. The machinery requisite will, from the nature of the power, be extremely simple in its construction, and moderate in cost, rotatory motion being directly obtained, and the methods of reversing, accelerating, retarding, and terminating the motion requiring no additions which can materially detract

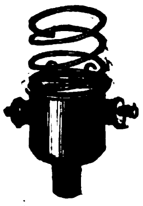

FIG. 2.—Connections for Lamp.

from the original power communicated." It was then pointed out that great improvements had been made in a short time in voltaic batteries, so that "the physiological, chemical, and mechanical effects which could be produced by batteries of a given quantity of surface, not above six years ago, can now be equalled by the action of batteries of a tenth part the size." "This," the author continued, "holds out very great encouragement to those who are engaged in the important task of applying electro-magnetism as a prime mover."

It is perhaps a little singular to notice that the connection of electricity with power and light has run somewhat side by side. The great development of the light during the past few years has directed attention to the connection with power, and we have already signs of immediate development in this direction. The success of the one seems to indicate the success of the other. At present the direction taken by inventors is the application of electricity for the transmission of power on railroads. The dynamo is to supersede the steam engine in front of the train, or to be applied to each carriage. This, however, may possibly prove a minor application, and the great advantages to be derived from such electrical transmission of power will be the providing every house with power that can be regulated and used when, where, and how desired—it may be to drive a sewing machine or to "rock the baby." The extended adoption of the electric light, then, seems to bring us face to face with the other problem also, viz., the distribution of power.

The success of Mr. Swan has brought the time of the general introduction of the electric light within a measureable distance. It is not for us now to discuss the comparative values of the Swan, Edison, and Maxim incandescent lamps; these can only be determined by extended trial. It must not be forgotten, however, that each of the three manufacturers has put a problem and attempted to solve it, and that this problem is not altogether the same, or the solutions would not be so difficult. Edison believes in a machine with low internal resistance, and a lamp with a high resistance. Mr. Swan, on the contrary, thinks the results obtained by this means not so satisfactory nor so economical as those obtained by the use of machines with a higher internal resistance and lamps of a lower resistance. Finality, however, has not been obtained by either inventor; for, if we mistake not, the lamps may and do receive modifications. The latest form of Swan lamp and its connections

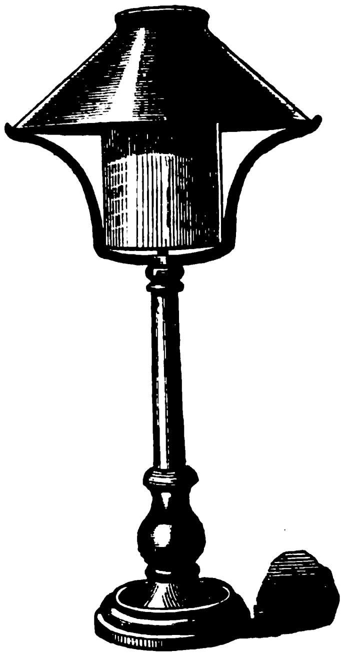

FIG. 3.—Table Lamp.

is extremely neat. Fig. 1 shows the lamp—in size a little more than two inches by three inches. At the top, through which the platinum connecting wires pass, is a glass plug. When the wires come outside this plug they are made into a little loop, as shown. The carbon filament, which is made of carbonised cotton, the cotton being first parchmentised by being acted on by dilute sulphuric acid, is made in the form of a loop, as shown. The reason of the loop shape is to obtain an equality of radiation in every direction, an equality not obtained by a simple loop, or the M shaped loop of Maxim. Fig. 2 shows the method of obtaining contact between the lamp and the line wire, and also the method of fixing the lamp. If the electric light is to supersede gas, there is no reason why existing gas fittings should not be utilised, and expense of replacement saved. Hence an ebonite or some other insulating base is taken and fashioned with a screw, as shown. This screw fits any ordinary gas pipe, as does the screw of a gas nipple. Two platinum hooks are connected through the base to the contact screws on either side, the line wires being brought to these contact screws. The loops of the lamp are hooked on to these hooks, and so far contact is complete. To ensure good contact whatever the position of the lamp, a

Digitized by Google

small spring is used, which keeps the loops and hooks closely together, and, at the same time, gives a certain amount of rigidity and flexibility to the whole. The replacement of breakages is thus confined to the lamp itself. If one is broken another is hooked on to the contacts, and this can be done by any ordinary person who is capable of handling china or glass at all. Of course, there are already a number of elegant chandeliers designed for use with these lamps. We can, however, illustrate but a few of them. Fig. 3 shows a table lamp. Most of these stands are made

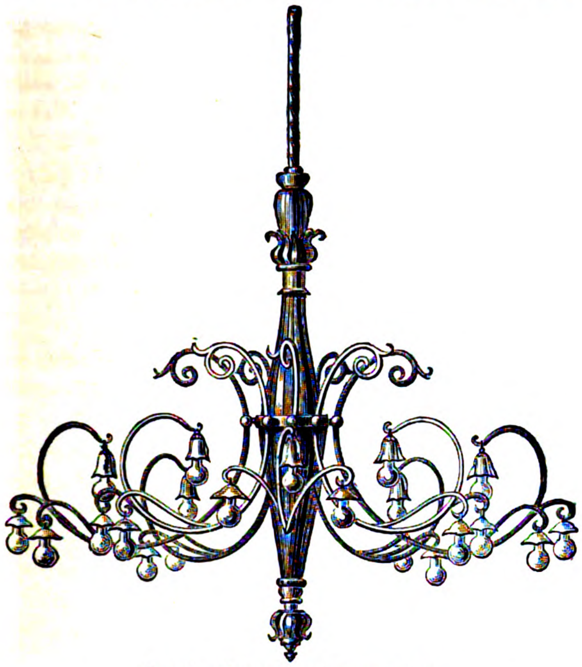

FIG. 4.—Chandelier for Swan Lamps.

with a plug, by means of which the current can be switched on or off, just as the tap of a gas pipe is turned on or off as required. One advantage possessed by the electric light is that no matches are required. The switch is turned and you have the light. There is no danger from an escape, and with ordinary common sense precautions there is no danger from fire. We may say that with any incandescent system there is absolutely no personal danger from contact with the

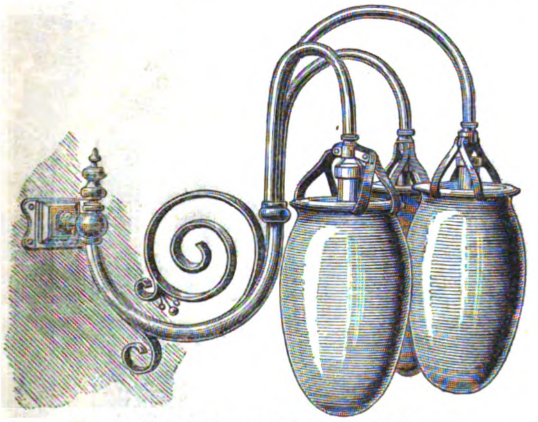

FIG. 5.—Swan's Lamp, as at the Savoy Theatre.

wires. Fig. 4 shows a hanging chandelier for a number of lights. Specimens of these lamp-holders may be seen at the Palace. Fig. 5 shows the arrangement adopted for clusters of three, as adopted at the Savoy Theatre, specimens also being shown at the Palace. Fig. 6 shows the large chandelier as exhibited in the furniture court. We believe there are 98 lamps on this chandelier. Messrs. Faraday and Sons have designed and constructed the chandeliers and fittings for the Swan lamps.

Mr. Swan has also given a great deal of attention to the manufacture of lamps for mining purposes. His latest form of lamp for this purpose is illustrated in Fig. 7. It will be seen that every care has been taken to avoid danger from accidental metallic contact, and that the lamp is, if not absolutely perfect, a long way in the right direction.

The current for the Swan lamps is obtained from Siemens's alternating current machines of the type known as $\frac{W_1}{D_7}$. It will only be necessary to mention anything peculiar in this installation, as these dynamos are well known. Take, then, the illustration in Fig. 8, where the dynamo, with a Gwynne fast-speed engine, is fixed on one frame. We believe this is the first installation in which such engines have been used. The number of revolutions is between 300 and 400 per minute. One dynamo supplies the current for 52 lamps in Messrs. Elkington's show room, for 133 lamps in the picture gallery, for twenty lamps in the office, and for one lamp at the machine—or a total of 206 lamps.

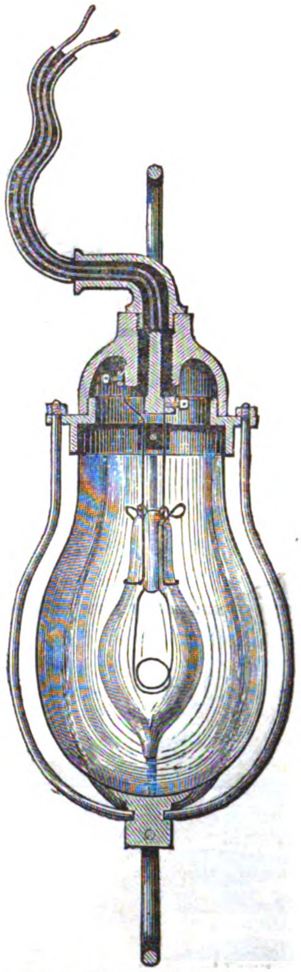

FIG. 7.—Swan's Miners' Lamp.

Each lamp under normal conditions gives a light of about 20 candles, and has a resistance, hot, of from 32 to 35 ohms. The lamps are all arranged in single multiple arc. Machine No. 2 supplies the current for the 98 lamps in the furniture court, for one lamp at the machine and two in the office, as well as for 40 and 30 lamps respectively in the dining rooms. These latter lamps, we believe, are exhibited by the Messrs. Siemens. The machine thus supplies a total of 171 lamps.

Since the opening of the Exhibition a third machine of the type SD_2 has been used to supply the current to about 40 lamps, some of which are in Messrs. Elkington's exhibit, others in a small furnished room adjoining the office, as well as the usual one at the machine. Although these constitute the exhibits of the Swan Company there are besides these a number of other exhibitors who use the Swan lamps. Among these we may mention Messrs. Elmore, Messrs. Hindley, Messrs. Patterson, and the Turner Gas Engine Company. Besides these the White House Mills Company are using some 130 lamps, and supplying the current with the Arago disc machine.

Digitized by Google

The whole of the arrangements of the Swan Company exhibits have been carried out under the superintendence of Mr. J. F. Albright. It is hardly necessary for us to mention that, as the time of closing the Exhibition is rapidly approaching, those who have not hitherto seen it should endeavour to do so, as it is undoubtedly the best exhibition of electric lighting ever seen, and one that is not likely to be again witnessed.

THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

At this Society's meeting, held at the Institution of Civil Engineers, on 11th May, Professors AYRTON and PERRY communicated a paper describing various instruments devised by them for measurements of electric lighting. Professor Ayrton, who acted as spokesman, remarked that, after the highly interesting lecture delivered on the occasion of their last meeting, what he had to say to the members that night would appear tame and dry; but in view of the great progress of electric lighting enterprise, some account of attempts made by Professor Perry and himself in supplying one of its greatest requirements—namely, the means of obtaining exact measurements, would probably prove acceptable. Repeating some portion of his remarks when describing their ammeter last year, Professor Ayrton said that one chief hindrance to exact measurement with ordinary forms of galvanometers was that the deflection never proportionately followed the current, nor had there been any easy method of calibrating the apparatus. Their first attempt at overcoming this difficulty was by altering the position of the needle, or, what amounted to the same thing, by tilting the coil in such a way that the magnetic moment of the coil increased with the deflection. To some extent this was successful; but still the deflection was not proportionate all along the scale. But afterwards it was found that, by altering the shape of the needle and altering the shape of the coil, an instrument could be devised which would rigorously answer to the varying strength of current passing through. Such was the ammeter, and this little apparatus would measure very accurately the arc currents, which ranged from 15 to 60 ampères on the one hand, or incandescent currents measuring as little as 2 ampères on the other. A voltmeter had been constructed on similar principles, but whilst this instrument was used in series, the ammeter was used in parallel. With these two appliances, and taking their respective readings, any part of an electric light circuit, of whatever kind it might be, could be tested so as to indicate the horse-power being absorbed. Their sensibility could be instantaneously halved by the insertion of a plug. A third instrument had been devised so as to give the result at one reading—a thick wire being used for the main current and a thin for the shunt. This instrument had been described by Sir W. Thomson at last year's British Association; and it gave the rate of doing work, or the amount of electric power being expended.

The next class of measuring instrument was one which dispensed altogether with permanent magnets, and which, therefore, had some obvious advantage to start with. It consisted of a coil with long iron needle enclosed, to the upper end of which was affixed an aluminium pinion and pointer. The needle had but very small range, or rather its deflection was very feeble, and its reading, therefore, practically true. To render the movement visually plain, the pointer and pinion came into play, and multiplied the deflection, so that a wide range of reading was obtained. As there was no initial magnetism, the needle was independent of the flow of the current, and the instrument could, therefore, be employed for either direct or reverse currents. Here the sensibility was increased or diminished by the use of springs, which could be adapted to the probable strength of the current to be tested.

For measuring the resistance of any part of the circuit another form of instrument had been contrived. In this two coils were placed at right angles to each other, the one of thick wire, the other of thin, with a needle in their midst. On joining the thick coil to the main circuit, the needle would assume a decided position. The thin wire coil was then connected in that portion of the circuit required to be tested, and the resulting deviation of the needle would indicate the ratio of the shunt circuit to the main circuit.

In order to measure large currents, ranging from 400 to 500 volts, without interfering with the lights, recourse had been had to a form of electrometer, similar to the well-known form devised by Sir W. Thomson, the pairs of quadrants and the aluminium needle being joined, as in his experiments, to the circuits being measured. The electrometer would, no doubt, play an important part in measuring electric light circuits when reverse currents were being employed, as, owing to the different inductive capacity of their coils, some of the instruments previously described were not trustworthy in respect to the measurement of such currents.

Professor Ayrton then described what might be styled a coulomb meter, that is to say, a device for measuring and recording the actual amount of current that had passed through the circuit during a lengthened period. An arrangement of vanes connected with a galvanometer of special form recorded by their revolutions the total current that had flowed through them. Mr. Edison, however, had, it now appeared, recently patented a similar arrangement, so that he might be said to have been beforehand with Professor Perry and the lecturer in this contrivance.

A simple form of photometer was then explained; but this has already been made public. The chief point of interest remarked upon by the lecturer in this relation was the fact that near observations always gave the highest readings, explainable only on the supposition that in the distant observations some of the green rays became absorbed and lost, especially when the condition of the atmosphere favoured their absorption.

Mr. OBACH then described several measuring instruments employed by Messrs. Siemens in their work of electric lighting, one a dynamometer connected with the two arms of the driving belt; another for measuring current strength by a species of torsion galvanometer, the coil being suspended; and the third a movable ring galvanometer, on the tangent principle.

As the evening was now too far advanced to admit of Professor Ayrton's second paper on Technical Education being read, a brief discussion ensued, in the course of which Mr. C. VERNON BOYS remarked that he had last year suggested the use of a non-magnetic needle for this kind of measurement; he also thought that the rolling contacts in the coulomb meter would be subject to faults which might seriously affect the resistance, and therefore the exactitude of the measurement—and this notwithstanding the assurance of Professor Ayrton that the meter, being in a shunt circuit, the results would not be affected. —Mr. GORDON testified to the dead beat character of the instruments described.—Professor FLEEMING JENKIN complimented the Society, from attending whose meetings he had been prevented for some years past, on the great strides it had evidently made in the interval.—Professor ADAMS also spoke in high terms of the ingenuity and comprehensiveness of the apparatus exhibited.—The usual votes of thanks to Professors Ayrton and Perry, and to Mr. Obach concluded the proceedings.

THE PROGRESS OF ELECTRIC LIGHTING.

At a meeting of the Royal Institute of British Architects, held on Monday last, at No. 9, Conduit-street, Regent-street, Mr. J. Slater, B.A., read a paper entitled "The Recent Progress in the Electric Lighting of Buildings," but the paper in reality covered a much wider field.

The room was illuminated by several forms of the electric light, the motive power being supplied by one of the new batteries of Messrs. Sellon and Volckmar. The Swan, the Lane-Fox, the arc, and other lamps were exhibited, the entire apparatus working admirably throughout the evening.

Mr. SLATER then read his paper, in the course of which he referred to the revolution which the last three years had effected in the opinions of scientific men as to the sphere of usefulness of the electric light. The author observed that this revolution was mainly due to the invention of incandescent lighting, which might be defined to be the unlimited power of concentrating large quantities of heat into small foci without consuming the heated body, which thus became a stable and unchanging point of light, in contra-distinction to the arc lights, in which the glowing material was continually disintegrating and burning away. The incandescent systems of electric lighting were based on the fact that, if preserved from combustion, carbon is practically infusible, and the chief difficulties in the way of making incandescent lamps lay in the fact that it was necessary to enclose in an exhausted glass globe an extremely thin filament of carbon, which must be in electrical contact with the wires outside the globe, and which must be able to stand an enormously high temperature. Messrs. Swan, Lane-Fox, Edison, and Maxim had overcome these difficulties in different ways. Incandescent lamps could be used with almost all kinds of dynamo machines, but they could also be worked with an invention which, as a practical means of supplying electricity, must be regarded as the outcome of the past year, but which would be epoch-making in the history of electric lighting, viz., the storage batteries, or accumulaters of electrical energy. The economic value of incandescent lighting was one of the most important points to be considered, and although at present the data upon which to found an opinion were but scanty, the cases in which the details of cost had been most accurately worked out tended to show that the economic value of the new means of illumination had been, if anything, under-rated. The readiness with which the incandescent lights lent themselves to any scheme of decoration was one of their chief attractions. There was no necessity for following on the lines of gas fittings, as the conditions were so completely altered, but points of light could be placed wherever they were required,

Digitized by Google

and there was no fear of blackening ceilings and decorations or of setting fire to the most easily-ignited materials. The progress of this system of lighting had been so rapid that architects had as yet had no time to turn their attention to its decorative capabilities, but when they did so they would find it fulfil every requirement for perfect lighting. Mr. Slater then alluded to the arc light systems, in which less progress had been made during the past year, but the sphere of usefulness of these systems had become more clearly defined, and the Mansion House was a good example of their adaptation to rooms of an exceptionally large size. If these large lights could be concealed and their rays reflected downwards from a large screen or a white ceiling a very pleasant and diffused light would be obtained, and the slight irregularities, due for the most part to the carbons, would be much less perceptible. Simplicity of construction was the great thing to be aimed at in these lamps, and the Weston arc lamp was a good example of their newest form, and this might be termed a strictly electrical lamp, as contrasted with a mechanical one. The great difficulty with which these arc lamps had to contend was in the nature of the carbons, in the manufacture of which but little improvement had taken place. The social aspects of this question were very important. These concerned the distribution and measurement of the electricity, the conditions necessary for reconciling the rights of the consumer and of the purveyor, and the risks to be guarded against. For electricity to compete with gas as a general means of illumination, it must offer as many facilities as its rival; and the Edison installation in Holborn, and that of the Swan lamps at the Savoy Theatre, showed practically that this condition was complied with. After describing these installations, the author explained the various methods of laying the mains, connecting the branches and arranging the lamps so that all were perfectly independent of each other, and showed how the strength of the current in the mains was cleverly regulated in proportion to the amount of work that it had to do. Perfect insulation throughout was the great desideratum, and if this point were always carefully kept in view, the dangers of electric lighting would be reduced to a minimum. Considerable attention had been given to this matter in America, and the Board of Fire Underwriters of New York had framed a code of regulations bearing on the subject. The Crystal Palace Exhibition was an exceptional case, as the installations were temporary, and the risks such as could not possibly occur in a well-devised permanent arrangement. Mr. Slater finally referred to the importance of the subject to architects, and recommended members of the profession to make physical science a subject of study.

The President of the Institute, Mr. Horace Jones, who occupied the chair, then invited discussion, first calling upon

Mr. Swan, who began by describing the paper in its entirety as the most complete and the most lucid lecture on electric lighting that had, in his opinion, ever been delivered [cheers]. He could confirm the statement of the lecturer that there was an essential economy in electric lighting, more particularly by the incandescent system—the form of electric lighting which he believed had the widest application and the greatest interest for the public. The comparison must be instituted between gas and electric lighting, for gas was really the light with which electric lighting would have to compete. If we made a comparison between the cost of producing a certain light by means of gas and by means of electricity we arrived by a simple process at something like this result:—2cwt. of coal, carbonised in a gas retort, turned into 1,000 cubic feet of gas, which would give a result of somewhere about 3,000 candle light for an hour burned under ordinary conditions in ordinary burners, in other words something like 5ft. of gas. This was giving gas the most advantageous conditions for its burning. If this same quantity of coal were employed to generate motive power through the medium of a steam engine, especially if it were supplied in the most economical form through some very large and well-appointed establishment where there was no waste of fuel, we could obtain for this quantity of coal 100 horse-power for an hour. This was a moderate estimate amply confirmed by a great number of instances, and the 100 horse-power which the 2cwt. of coal would give would be capable of producing through the medium of incandescent lamps 20,000 candle light. It was necessary to take into account with the generation of gas that gas was not the only product yielded by the carbonisation of coal. There were other products of almost equal value. The gross cost of 2s. 9d. in producing 1,000 cubic feet of gas was reduced to the extent of 1s. by the sale of the secondary products. With even so liberal an allowance as this, still we had a large advantage over gas in electric lamps. If we assumed the products to be sold to buy other 2cwt. of coal, of course we could get another 1,000 cubic feet, which would give 3,000 candles, thus raising the quantity to double, viz., 6,000 candles, but still we had the difference between six and 20 in favour of the electric light. An economy of this nature was only obtainable on condition that the motive power was produced in the most economical manner—as, for example, in large electric lighting establishments, from which he hoped facilities would be given in connection with the proposed legislation now before Parliament. Facilities for the investment of capital for the creation of large electric lighting stations should be given, or otherwise the public would be deprived of the benefit of a perfectly innocuous illuminating agent, such as this was. There was more danger of this than of the whole thing becoming a monopoly. He augured well from the fact that the assistance of architects was now to be given to electricians in bringing about a change in the matter of domestic illumination. The hands of electricians were so full in dealing with the physical aspects of the subject that the mere decorative section of the work might safely be left to architects.

Mr. Lane-Fox said the danger apprehended from the use of the electric light was a mere myth. He believed it to be a monster conjured up in the brain of the gas vendor and the insurance broker, who naturally enough wished to make the most of it [laughter]. There had, no doubt, been certain unpleasant results from the improper application of electricity. One or two people had been killed, and a few places had been set on fire by electricity [a laugh], but similar results would accrue from the improper application of fire or almost any other agent. If we set light to a fire in the middle of our room we could not expect it to go on burning without doing damage, and so with electricity. Treat the agent improperly and there was sure to be danger. The dangers could be divided into two heads—those which resulted from physiological effects, such as shocks, and those which produced fire. Electric shock was due solely to high tension in the electricity. The electricity must be driven to a very high tension before any appreciable effect was produced. When applied to public lighting, as it undoubtedly would be, it would be impossible to produce any physiological effect. The lighting of this room was produced by electricity at a tension of some 60 units of electrical pressure, and he would not mind holding the wires, and guarantee not only the absence of shock, but the absence of any feeling at all.

Electricity would be supplied at a low tension, and then would not be at all dangerous. It was, in fact, infinitely more practical and convenient to supply it at a low tension, its subdivision being easier, and its economy beyond question. Many persons fancied that by taking hold of dynamo machines, and particularly the Brush machine, that they were sure to be struck dead! When it was necessary to drive the current a great distance and to have a great length of wire, it was highly desirable that the electric current should be capable of overcoming resistance, and the only way in which it could be made to do that was to drive it at a very high tension, for when applied at a low tension it was in a very much lower quantity. As to the second danger, that from fire, it only arose from careless manipulation. He believed that in the earliest days of gas the leakage was about 50 per cent. of the total product. After a time they managed to reduce it by 30, and now he believed it was no more than 3 per cent. With electricity he thought they could make a fair start with insulation on a much higher scale than the best insulation of gas, because their knowledge of the subject, thanks to telegraphy, &c., was much more perfect. The whole subject had been thoroughly thrashed out, and there was very little doubt in the minds of those who understood it. Many people having very little experience in the matter their ideas of insulation were certainly crude, and hence dangers had arisen. After a few remarks on the subject of storage batteries, which had been very much misunderstood, Mr. Lane-Fox concluded by saying that this was, perhaps, too purely technical a matter to enter into fully just now.

Mr. Fowler asked Mr. Slater whether it was possible to order a supply of electricity for a required number of rooms, just as you ordered a supper for a given number of guests at so much per head [laughter].

The President said that in the course of his paper Mr. Slater had referred to the first essay in electric lighting made at the Mansion House. He had the honour of attending the banquet on that occasion, and they had scarcely finished supper when they were in total darkness [laughter]. As to the remarks of Mr. Swan touching the comparative cost of gas and electric lighting, he would not be prepared to give that gentleman the verdict entirely in his favour without hearing the gas companies on the other side. He had to make enquiries a little while ago of a very well-known man, and was distinctly informed that to light a very large area some economy would be found upon the side of electricity, but he intimated that to obtain this economy he should be compelled to use the arc light, and not the incandescent, and that he considered the difference as four to one in favour of the arc light as compared with the incandescent. He was quite sure the Institute would not separate without passing in the most

cordial manner a vote of thanks to Mr. Slater for his admirable paper.

Mr. Blomfield said that in common with the other members of the Institute he had listened with the utmost interest to the paper, and they owed Mr. Slater a real debt of gratitude. The hint he had given as to the necessity of young architects paying some attention to physical science was of great importance. If, as no doubt would be the case, electricity were to be the light of the future, all architects must make it their business to understand how that light was produced, and how it could best be adapted to buildings. Certainly they would not require to be too much wedded to the old associations of gas and candle lighting. It was quite clear that electricity could be applied in ways which were entirely new without any danger of injury to the building, or from blacks, or anything of that sort. He had great pleasure in proposing a cordial vote of thanks to Mr. Slater.

Mr. Hayward said he seconded the motion, first, because of the pleasure the paper had given him, and secondly to supplant some remarks it contained relative to the electric lighting experiment which had been carried on at Godalming. He knew some of its successes, and some of its difficulties. The origin of the idea at Godalming was this :—A quantity of waste water was continually running from a certain mill, and it occurred to the millers that this could be turned to advantage to light their own factory, and at the same time light the town. They had a certain number of water wheels that they did not always use, and as we all knew the river Wey passed through the town. There came certain floods in the river, as often happened directly after the electric lighting was carried out, and there was considerable failure, and it was well to understand the failures of the system as well as its successes [hear, hear]. For several weeks the incandescent lights, to which he looked with great promise, gave no light at all, and everybody in the neighbourhood was calling out against them, whilst there was great fear and great anxiety on the part of those who were interested in the subject lest the town should go back to gas lighting. This was very likely, for many of those who were the most in favour of electricity were for giving it up entirely. He believed at that moment Messrs. Siemens stepped in rather than that the whole subject of electricity should be put aside by such an experiment failing, and he believed they had established a steam engine, and had given up the lighting of the town by water, not that the water itself failed, but simply from the circumstance that there was not sufficient power in those water wheels to do what they were required to do, and occasionally there were floods, and there was the want of an accumulator to act as a gasometer. The success of working by water would have otherwise been accomplished. As it was, it was simply put aside for a time, and the present success he might now say was considerable. It was very satisfactory to him, as one living in the neighbourhood, to find that the experiment, though it did not succeed at first, was not allowed to throw a slur upon electric lighting, but that it was able to be continued, and that when Mr. Slater went down to look at it he was able to return with the favourable report he had made in his paper that evening. If they would only carry the wire as far as his house he would use it himself.

The motion was carried unanimously.

Mr. Slater said that under ordinary circumstances anyone who ventured on two successive occasions within little more than a year to read a paper here on the same subject might, he thought, not unjustly be accused of presumption. But the progress of the electric light had been so rapid, the novelties in its use had been so striking, and the general interest taken in the subject was so exceptional, that electric lighting stood almost in a category of its own. Hence, although he felt considerable diffidence in acceding to the request of the Council to give another paper, he hoped at the end he might be able to interest his hearers. But he felt that little thanks were due to him. If it had not been for the kindness of the gentlemen who had assisted him in showing the lights exhibited in the room, he would have had a very hard task, and his endeavours would have fallen very flat. In fact, he would have been very much in the position of the theatrical manager who, having announced the play of *Hamlet*, with a full cast, found himself on the evening of the performance obliged to read it himself, because all his performers were not in a state to exhibit themselves [laughter]. His thanks were particularly due to Messrs. Sellon and Volckmar, who not only in the kindest way placed one of their new batteries at his disposal, but had been at a great deal of trouble in fitting up the wires. He thought that the Institute owed a great debt of gratitude to them for showing what could be done by means of incandescent lights. With regard to Mr. Fowler's question as to whether you could send to Mr. Volckmar's for a supply of electricity as you could send to a *restaurateur* for a dinner, no doubt Mr. Volckmar could do it. With regard to the arc light being economical, there was no doubt that it was so. But it must be borne in mind that, although you got a greater amount of light, yet in the immediate neighbourhood of the arc itself you got a great deal more light than was wanted, so that it might be more economical to use several small lights rather than one large one, although the amount of light obtained might be less. As to Godalming, Mr. Hayward had given precisely the facts. They tried water power, but found they could not get on, until Messrs. Siemens Brothers took up the work with good results. With regard to another question—as to some lamps burning clearer than others—this was due to the variation in the resistance not being equal. If the resistance of the filaments were precisely the same the current would work them to precisely the same amount of brilliance. With regard to water power, it could be used effectively, because Sir William Armstrong (at Newcastle) illuminated his picture gallery by a turbine driven by a waterfall in his own grounds ; but you must get a certain fall to do it. In conclusion, he thanked the meeting for the kind way in which they had received his paper.

On the suggestion of the President, a vote of thanks was also passed to Messrs. Sellon and Volckmar for their important contribution to the interest of the evening.

The proceedings then terminated.

INSURANCE COMPANIES AND ELECTRIC LIGHTIN G

The second lecture of this course was given at King's College, on the 10th inst., by the evening lecturer in physics, Mr. R. E. Day. The lecturer commenced by describing the various ways in which the strength of an electric current can be measured, and illustrated these several ways by showing the action of galvanometers and electro-dynamometers of various kinds. For many years considerable confusion has existed on account of the want of some common system of nomenclature for the different electrical quantities, and one of the great benefits of the recent electrical exhibition at Paris was that at a congress of electricians which was held there, certain definite agreements were come to as to the units of electrical measurement which should be adopted for the future. It was then decided that the unit of current should be called an ampère, the name being derived from that of a celebrated electrician who lived in Paris in the first half of this century. The lecturer then went on to say that whenever electricity comes into general use as an illuminant it will be absolutely necessary that each consumer should have an electric current meter, so that both he and the company which supplies the electricity may know exactly how much he uses, and also that he may not have to pay for more than he has actually used. The new Edison electric light meter, which was lent for the occasion by the kindness of Mr. Francis Jehl, of Menlo Park, was then exhibited, and the principle of its action explained. If an electric current, no matter how it is generated, be made to pass through a compound liquid it generally decomposes it, and the products of the decomposition gather at those places where the current enters and leaves the liquid. Now, it was proved by Faraday that the same quantity of electricity, that is, an electric current of a given strength, decomposes chemically equivalent quantities of all the bodies which it traverses. For instance, in the decomposition of water it will be found that for every 18 parts of water decomposed, two parts will be hydrogen and 16 oxygen; in order to form water from its two component gases we must take them in this ratio. It follows from this law that the quantity of the substance which is decomposed is proportional to the total quantity of electricity which passed through it, and is independent of the time during which the electricity passed ; and the quantity corresponding to the passage of one unit is called the electro-chemical equivalent of the substance. Thus, when one unit of electricity passes through a solution of sulphate of zinc having zinc electrodes, the action is as follows :—For one unit of electricity, one electro chemical equivalent of zinc would appear at the cathode, one electro-chemical equivalent of oxygen at the anode, and unite there with the zinc and sulphuric acid to form another electro-chemical equivalent of sulphate of zinc, and take the place of the one just decomposed. This action continues and keeps on depositing zinc on the cathode, and taking zinc off the anode. This is the principle of action of Mr. Jehl's current meter, and no matter how much current passes through it, for every electrical unit or fraction there will be a corresponding number of units or fractions of a unit of the metal deposited. The meter itself consits of two bottles, each containing two plates of zinc in a solution of zinc sulphate, and the current in passing causes one plate to increase in weight at the expense of the other. As, however, if the whole current passed through the bottle this change would go on too rapidly, a properly proportioned shunt wire allows just 1-870th of the electricity going to the house main to pass through the meter. The estimate of the quantity consumed is made once a month by weighing the plate that has received the deposition.

Digitized by Google

The second bottle is a check cell, and the party that has access to the one has not access to the other. The second or check cell is taken out once a quarter and the deposit weighed. In the bottom of the case containing the cells there is a very ingenious arrangement of shunts, and also a very ingenious thermo-electric arrangement, which Mr. Edison has devised in order to prevent the freezing of the sulphate of zinc solution in winter. The latter part of the lecture was devoted to the principles of action of dynamo machines.

ELECTRIC CONDUCTION AND DISCHARGE.

BY F. E. UPTON.

The question of the nature and the vehicle of the electrical discharge is an important one, and its determination will contribute greatly to the solution of many interesting problems in cosmical physics. It is desired in this article to call attention to some recent advances that have been made in that direction.

The view that the phenomenon is one of pure conduction, though it has received the attention of eminent physicists, can be said to be no longer entertained.

When a conductor is made to connect two poles or electrodes which are at a different potential, it is well known that the greater the cross section of the conductor, or, in other words, the more of the conducting material is laid bare by a cross section, the *less* resistance will be offered to the union of the electricities of the two terminals, and the greater will be the ensuing current, with a given E.M.F.

Now, in the discharge, the contrary is observed directly. This characteristic of conduction is absent when the discharge takes place; in a tube containing air, the greater the pressure (above a certain inferior limit), or the more of the conducting material there is laid bare by a cross section, the *greater* will be the resistance to the passage of the spark, and the nearer together the terminals will have to be brought to effect a spark, with a given difference of potential. Sir Wm. Snow Harris, in 1834, made an attempt to grasp at the law governing the relation of the length of spark to pressure; and he then stated that the length of spark is in the simple inverse ratio of the pressure. Gordon, in 1878, made a series of experiments to test this law ("Elec. and Mag." II. 55-62). He found that from a pressure of about eleven inches to that of the atmosphere Harris's law held approximately good.

Representing resistance by r, and matter laid bare by cross section by s, in the case of conductor $r = \frac{1}{s}$; in the case of discharge 92 of $r = s$, approximately. Thus there is in question two entirely different order of phenomena.

Another distinctive characteristic of conduction will be recognised in the fact that whenever there is any conductor at all, however small and however long it may be, connecting two poles, some degree of current will flow, as long as there is any difference of potential. With discharge, however, a certain lower limit of distance apart of poles, and of interposed matter, is requisite for any current at all, and when that limit is reached the spark passes, instantaneously, and the discharge commences.

Whether the current passes by conduction or discharge heat is equally developed; in the conductor in the one case, and in the interposed matter in the other. This common development of heat does not in any way assimilate the two phenomena. The condition of affairs in the two cases will perhaps become obvious if recourse is had to the corresponds hydraulic analogy.

Imagine a pond of water held in place by a dam, with a pipe leading from the bottom of the dam for the purpose of drawing water from the pond. The smaller that pipe is in section, the smaller will be the current of water flowing through it under a given head, and a certain amount of heat will be developed by friction of the water against the interior of the pipe; moreover some degree of current will flow as long as the pipe has any size of cross section at all. That corresponds to conduction. Now let the pipe be imagined closed to the exit of water; as long as the dam is sufficient, no current at all will flow; but suppose the dam be diminished in thickness gradually and constantly, a point will be eventually reached when it will no longer suffice to hold back the water, which will break through the impediment; the friction of the water against the fragments of the dam, and of those fragments against each other, will develop heat as in the first case. That correspondends to the discharge.

By this analogy the difference between conduction and discharge is clearly apparent. A conductor between two points at a different potential never offers any *resistance* to the passage of the current, strictly speaking. Instead of saying that a slender wire offers more resistance than a thick one, it would give a better understanding of the matter to say of the latter that it offered a freer passage to the current than the former. In the case of discharge, on the contrary, the matter interposed between the points acts always as a bar, or resistance to be overcome, and the more there is of it the more resistance. It is never an aid or way.

Mr. E. Goldstein, in the *Annalen der Physik*, describes an ingenious experiment bearing upon this point, which, if not conclusive, is entitled to some consideration. In a discharge tube which was filled with dry nitrogen he placed a little sodium, which could be vaporised by heating. The positive light had a purplish red colour, but in the vicinity of the sodium it was of a golden yellow. By careful heating and manipulation the upper half of the tube could be kept red and the lower half yellow. Now the tube was brought over and near, in a horizontal and equatorial position, to a powerful magnet. The discharge light was repelled as a slender thread to the opposite (upper) side of the tube, but it was a pure reddish thread, and showed no trace of sodium yellow; so the sodium was not displaced or repelled under the influence of the magnet, as it would have been had it been a *conductor* of electricity.

There has been considered the possibility that metallic particles thrown off from the electrodes might be the conductors of the current. To determine if this were the case, Mr. Goldstein made use of a tube with platinum electrodes, in which the light from the cathode was deflected by a second cathode. The light alone underwent this deflection, while the minute particles torn off from the platinum, which lodged on the opposite wall of the tube and formed a sort of mirror there, went exactly to the same point after the deflection of the light, as before. There was thus no connection between the light of discharge and the abraded metallic particles.

But the most elegant demonstration in this matter has been furnished by the experiments of De La Rue and Müller; they arranged that the discharge of 2,400 chloride of silver cells should pass through a circuit consisting of a vacuum tube and a large variable resistance, R—; now with different resistances R_1, R_2, the resistance of the vacuum tube formed a varying fraction of the whole resistance; and, according to Ohm's law for the fall of potential along a conductor, the fall of potential along the vacuum tube should have been variable, had its function been that of a conductor. It was found in fact, however, that the fall of potential along the tube remained constant, no matter what resistance was introduced in the remaining part of the circuit between the poles of the battery, showing that the discharge was not a case of true conduction, but that even at the lowest pressure it was disruptive.—*Science.*

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).

The seventeenth ordinary general meeting of the above Company was held on the 12th inst., at the Cannon-street Hotel, under the presidency of Sir James Anderson, the vice-chairman of the Company.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting and the minutes of the last meeting, which were confirmed. The report of the directors, which has appeared in *The Electrician*, was taken as read.

The CHAIRMAN: I have a few remarks to make on the report, but before saying anything on that I must first apologise for the small number of directors present to-day. Lord Monck, who I dare say you know is Lord-Lieutenant of the county of Dublin, cannot leave his post, owing to the late lamentable event. Mr. Chaytor, one of our most esteemed, respected, and invaluable colleagues, I am sorry to say, is very ill, and Sir Thomas Fairbairn has been summoned to a committee of the House of Commons for two o'clock to-day. You must therefore take the few members of the Board, who are here as representing your interests. The only remark of any great moment is to tell you of the condition of our cable. When we last met you we had a fault in the shore end, and the fault was so minute that we were not quite certain whether it was in the shore end at Pernambuco, or in deep water. However, we sent a vessel out to remove the fault, and did so, and she found the cable seaward of her, towards St. Vincent, in as good condition as when it was laid, but the shore end, about eight miles inward from that point, we found we must renew. The cost of that will very likely be something like £5,000, as it is a very heavy class of cable. That, however, is not a very great matter. I don't know any telegraph company—and I am connected with many others—which has required so little money to be expended on repairs as in the case of this Company. It has had singular immunity, and in that respect this Company is the envy of every other telegraph company in the world. The next matter I have to refer to is your traffic. For the half year there was an increase of £675. Each half year in all companies has a different value—that is to say, there is one half year of considerable value, but in the other half year the traffic goes down. Comparing the last half year, however, with the corresponding period of last year there is an increase of £4,600; and the increase from the 1st of January to the 14th

Digitized by Google

April in our traffic has been £3,060, while the working expenses have decreased by £243. That is all I need say about the traffic. I have to refer now to the resignation of our director in Brazil, Mr. Pinto. He had to leave us because he was called to join the Ministry, but I am happy to say that we have appointed another good man, who has acted as our solicitor for a great many years out there, to represent us. It is not likely you can know of the daily, the constant correspondence respecting your affairs in Lisbon and Brazil, necessitating gentlemen of influence to represent us with whom we can correspond, and whose time we can call on for that purpose in the distant parts for our system. We are especially fortunate in having Mr. Silva to represent us at Lisbon. I have here a few remarks as to Mr. Jay Gould's opposition cable, but I don't think I need say much about that. We only know that Mr. Gould has a concession for an opposition cable to go from Brazil to North America. Whether he will lay it or not I don't know, but I may as well tell you plainly that the traffic he would compete for, is about fifteen per cent. of your gross traffic. If, therefore, he does lay the cable it might become a matter of competition as regards the traffic, but we have so much in our favour as to the European traffic that I do not fear at all. I should not sell a share for that, so far as I am concerned. I don't know that there is anything more worth taking your time up with. This is a very nice report, and very short; and everything is before you so completely that really nothing is left for one to say. All our investments are there stated; and the traffic is given for each month since the line was open. The cable is in good working order; the reserve fund is growing, and if the traffic goes on as it is now, we hope to pay you a still larger dividend next year. With these remarks I beg to move, "That the report and accounts of the directors to the 31st of December, 1881, now submitted, be received and adopted."

Mr. Frederick Youle seconded the motion, which was carried unanimously, without discussion.

On the motion of Mr. J. Anderson, seconded by Mr. Lewis Wells, a vote of thanks to the chairman and directors was passed.

The Chairman briefly acknowledged the vote, and the meeting then separated.

THE RIVER PLATE TELEPHONE AND ELECTRIC LIGHT COMPANY (LIMITED).

The statutory meeting of this Company was held on the 12th inst. at the offices, 6, Lombard-street, Sir Julius Vogel, K.C.M.G., the chairman, presiding.

The Secretary (Mr. Charles Curtoys) having read the notice convening the meeting,

The Chairman said: Gentleman, I am very sorry that anyone has taken the trouble to come to the meeting, for there really is no business to transact. The secretary omitted to state in the circular that there is no business. This meeting is simply held because the law requires that within four months after the registration of the Company the first general meeting should be held. There is no business to transact, but as regards the progress of the business I may say that the Company has taken over the business for Buenos Ayres; we have a local board, a very good local board; we are extending our operations daily, and I hope the business will turn out to be a very good business. I have no resolution to propose. Several shareholders at this moment entering the room, the Chairman continued: I may say, for the benefit of the last shareholders who arrived, that this is merely a statutory meeting, there is no business to transact, and all I have to report is that we have taken over the business in Buenos Ayres, that we are extending our wires and increasing our number of subscribers every day, and our manager there and the local board seem to have the opinion that we have a very fine chance there. I hope it will prove so. The difficulty hitherto has been in supplying a sufficient number of telephones.

Mr. Freeman: What is the nature of the concession from Buenos Ayres? Is it anything in the shape of a monopoly?

The Chairman: We have no special concession. We have the right to run wires, but not an exclusive concession. We have the right to run wires and to carry on the business of telephone exchanges.

A Shareholder: What is the number of our subscribers at present?

The Chairman: About 300.

A Shareholder: Anybody else can do the same thing.

Mr. Curtoys: Well, we have an established system.

The Chairman: There is one other company at work there.

A Shareholder: There will be two centres for exchanges.

The Chairman: We have five exchanges already, and we are opening one at Montevideo. At Montevideo we have some exclusive rights. We have, in fact, exclusive rights in Buenos Ayres. The Pan Telephone Company has also exchanges, but our manager reports the Pan subscribers are daily coming over to us.

A Shareholder: Is it not a very confusing state of affairs to have more centres in a town than one?

The Chairman: Well, of course it is better to have one, and we are negotiating to amalgamate the two, but I am not in a position to give you the particulars; but in either case we are quite satisfied with the prospects of our own system. The Pan telephone is a new telephone. I do not think it is any use in any part of the world except Buenos Ayres.

A Shareholder: The electric light is a different thing altogether.

Mr. Curtoys: The electric light we have not done anything with.

The Chairman: We are in treaty for obtaining the Edison light, but we have not arrived at a conclusion yet. As there is no business to do, if there are no more questions to be asked we will declare this meeting at an end.

Mr. Adams proposed a vote of thanks to the chairman.

Mr. Panser seconded the motion, which was put and carried unanimously.

The Chairman: I hope we shall give satisfaction. I believe we have a very good property, and one we shall be satisfied with.

The proceedings then terminated.

THE HAMMOND ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).

The statutory meeting of this Company was held on Thursday at the Cannon-street Hotel, Sir C. L. Young in the chair.

The Secretary having read the notice convening the meeting,

The Chairman said: You are aware, gentlemen, that this is merely a statutory meeting of the Company, which is called simply for the purpose of satisfying the requirements of the Acts of Parliament regulating joint stock companies under the Limited Liability Act. To-day we have no accounts to submit to you. We have no report to offer for your adoption; but perhaps you would like to have some sort of idea of what we have been doing in the brief period of our existence. You are aware, from statements in the original prospectus of the Company, that we purchase from Mr. Hammond the whole concessions that he has obtained from the Anglo-American Brush Corporation for using and selling this apparatus for producing the electric light on their system in the important counties of Northumberland, Cumberland, Westmoreland, Durham, Lancashire, Yorkshire, Hampshire, Isle of Wight, and Sussex, and also certain valuable privileges he has secured from the Brush Corporation in the City of Westminster. Now, the consideration we gave Mr. Hammond for this was £35,000, in fully paid shares, and also certain founders' shares, which are entitled to participation in the profits of the Company after 10 per cent. has been paid to the shareholders, and after a certain amount has been set aside for reserve fund. Considering the values which, in public estimation, these concessions have risen to in the provinces, I do not think this amount can be said to have been a very extravagant one. After the formation of the Company we acquired from the Brush Corporation the concessions for Warwickshire, Staffordshire, and Worcestershire for the sum of £6,000, the amount for which Mr. Hammond had originally secured them. Well, gentlemen, when we accepted the responsibility of the conduct of your affairs we found that we had a very excellent basis to start upon. Mr. Hammond had been pretty well round the country, certainly in the north, and you know what a good thing it is to have a good beginning, and "nothing succeeds like success." The Brush apparatus, as you are aware, has been subjected to severe tests and to severe competition, but the proprietors have never been afraid of either, and I think, so far, the results have amply justified their confidence. We have been able in various parts of the country to demonstrate the great utility of the Brush light for every purpose where extensive lighting is required, and where it is available; and, without going into any details to-day, I may state after an exhaustive trial of our arc light with a sixteen-light apparatus it was found to be perfection by parties who tried it, and they have ordered a forty-light apparatus for the autumn. You will understand that the period of the year was not the most favourable for the introduction of artificial lighting. People do not think so much of that when the days are drawing out as when they are closing in; but the assurances we have received have been such as to justify us in giving large orders to the parent companies to enable us to meet all the demands which we believe we shall be called upon in the autumn to supply. We have been successful in cotton mills and in iron mills, where the dust and the dirt render the working of the electric light somewhat difficult, but over these difficulties we have been able to triumph. The well-known Oldham firm, Platt Brothers, has given us an extensive trial, and has eventually adopted our system. We have had success in galvanising works, and, I am very happy to add, we have been selected by one great railway company in the north to do their electric lighting, and we have already erected considerable plant for that. We have great confidence that another railway company in the north will shortly give us an extensive order for the purpose of replacing a defective system of electric lighting which they had had at work; and, I dare say, you may have observed some time ago in two or three of the London papers it was stated that at railway stations the electric light had proved a failure. The papers did not mention that that was one system only, and I saw very much the same observation made again last night. I am not going to trouble you much to-day, as I think Mr. Hammond would like to have a word or two to say. With regard to the formation of sub-companies, we have thought it the wisest policy to endeavour to enlist local sympathy and local assistance by the creation of local companies, and accordingly we have entered into agreements with parties in different towns and cities, and counties, to which, for a consideration, we hand over our rights and concessions, but at the same time we so contrive our agreements that we retain a valid interest, and do not lose all those interests in those counties, and towns, and cities. We have received special offers from responsible persons for the privileges we possess in certain counties, and also for the City of Westminster. We think these sub-companies will be of very great service to us, and the business that will speedily arise through their formation will be a source of considerable profit. Well, I do not propose to detain you any longer. It is enough to add we have very great confidence in the material at our disposal, and we look forward cheerfully to the future. It has become almost a common-place remark to say that the electric light is in its infancy. I dare say it is in its infancy, but it is a very fine and promising infant, and it scarcely requires a prophet to say that probably its adolescence will justify the promises of its youth. We have to fight with vested interests, and with great monopolies, and those do not die easily. However, nothing runs into perfection all at once, and we must have a little patience. We must not expect an immediate revolution in the systems of illuminating our streets and our public places and our private dwelling houses and our manufactories. All changes that are worth having come after experiment and patience. You will remember how it was said once by a very able writer, "We have given the lightning a situation in the Post Office;" I can only say I think we are now on the eve of the time when electricity is going to be called to give us some of the greatest benefits of modern times. Now, I think Mr. Hammond would like to say a word or two to you.

Mr. Hammond said he felt some difficulty in knowing exactly what ground to take up before them that day. Their Company was, of course, on the threshold of its career, and though during the past three or four

Digitized by Google

months they had had very satisfactory results from its working, it would, perhaps, be more in order if he should start by giving a summary of what they were likely to do in the future rather than refer to what had taken place during what he must call the babyhood of the Company. He ventured to dwell for a short time on this point, because with the whirl of excitement that was going on at present it behoved those who were foremost in the business of electrical engineers to be calm and perfectly to understand their position, and the shareholders of any company, certainly such a company as theirs had become, should go away from this meeting knowing something about the property that they possessed and the prospects that were before them. He said that the Hammond Company had taken up the position of being electrical engineers. Now, in the applications of electricity there was one branch which stood foremost, and that was electric lighting. In fact, electric lighting had taken so strong a hold upon the public, that one was apt to forget that there was anything else connected with electricity; but in addition to electric lighting there was also the question of power, and without attempting in any way to detain them unnecessarily, he would like to say two or three words on the question of power. In many places throughout England there were manufactories which were compelled to waste a considerable amount of power every night. There were mills which, in the ordinary course of their business, generated an immense amount of heat, and if that could be utilised it could be converted into power, or into energy, which afterwards could drive the machinery, and which, indeed, could drive machinery at a distance. Therefore, there was ample scope for an electrical engineer who carefully kept his eye on every branch of the subject to work out a most lucrative business in utilising the waste power which at present was lost. In many places this waste power took place at a spot where the power was not so useful as at a distance. They were probably aware that, by the help of the dynamo machine, they were able to transmit the power. It was, in fact, transmitted to a colliery some fifteen miles distant, and, although the opponents of the Brush system said it would take a wire as thick as his hat, they were able to do it with a wire as thin as a quil pen. There was a colliery in the north of England where a 300 horse-power engine was used 1,000ft. below the ground. It was evident that the amount of cost contingent on such a scheme as having 300 horse-power pumping water below would be much minimised if all the machinery were at the top, and if by the substitution of a wire the power was conveyed down below. He thought it was well to dwell on the question of the latent force which they had not yet touched, but which might prove most lucrative in the future. With these few words with regard to power he would turn to what was more familiar to everyone—the question of lighting. Now, it had been said within the last two days by one of the leading journals that the electric light was not wanted, that the *furore* which exists in every direction with regard to electric lighting was a great mistake, that practically the Hammond Company had talked a good deal, they really had done nothing worth speaking of, and certainly had done nothing which had helped forward the work in any particular direction. Now, if they were in such a position that only those people would take their electric light who fancied it, or happened to be shareholders of the Company, he was going to say that they would be, of all men, the most miserable. They must show that there was a reason for the electric light Now, the question of lighting most familiar to Londoners was the question of the lighting of houses. They were aware of the fact that the lighting of a man's business premises was much more important to him than the lighting of his home; the application of a new thing there was more essential to him than its application to his house. For instance, a man grudged no expense which he thought beneficial to his business; whereas a man looked twice at a £5 note in household expenses, and, therefore, though he regarded the lighting of houses as of immense importance, he put it aside for a moment while he dwelt on the lighting of business premises. Throughout this country there were firms which carried on their operations day and night, as far as it was possible to do so; but in many of their premises it was utterly impossible to carry on some operations by any artificial light except the electric light. He made the statement advisedly, and he said it with all confidence. He would give an instance. They were all familiar with the process of rolling blooms of iron, as they were called technically in the trade, into iron rails, and blooms of steel into steel rails. The operations at large works, like those of the Ebbw Vale or the Bolckow-Vaughan, were most rapid. The iron stone was excavated from the hills in the morning, it was brought into the works, and the next day it was shipped in the form of finished rails. Now, when they were dealing with a company whose capital was £2,000,000, and whose out-turn of rails reached 8,000 tons per week, they would readily understand that every part of the works must be so constituted as to keep pace with the other. When the steel was rolled out into rails they were turned out all straggling and crooked, and they had to lie on the ground until the next morning, because the process of straightening those rails was impossible to be done by night. At Bolckow-Vaughan's they had tried various processes to light up what was technically called the rail bank. They found it impossible. Well, this Company had made it possible by the aid of the electric light, and works like Bolckow-Vaughan's, that otherwise would have to double the cost of the plant in particular directions, were enabled to use the same plant night and day by this new artificial light. Manufacturers had also told them that, since they had had the electric light the working power of their men had been uniform throughout the day, and the work done before eight o'clock formerly was practically only 50 per cent. of the work done now, and the work done after four o'clock was 50 per cent. less than that which was done now. Not only, therefore, could idle plant be utilised during the night, but better work could actually be got. The late Mr. Gibb, engineer to the Palmer Shipbuilding Company, built a shop some few months since, having no gas whatever in it; he whitewashed it, and asked the Company to come in and see what they could do. The shop lighted with the electric light, and with not a single jet of gas, actually yielded 25 per cent. better results than the one lighted by its side with gas. The men got twenty-five per cent. better wages, because they were paid by the piece; but it was an immense thing to feel that by the use of their light twenty-five per cent. more work could be obtained. Having referred to the question of house lighting, he said it had been asserted that fifty new electric lighting companies could be started every day, but he contended that none could be started with a sound basis. He referred to several failures which had been made by similar undertakings, and stated that it was the fault of the systems and not of electric lighting. In conclusion, he expressed his greatest confidence in the future of the Company.

A vote of thanks to Mr. Hammond, and also to the chairman and directors, terminated the proceedings.

ELECTRIFIED WINE.—M. A. Angelier writes to *La Nature* detailing some experiments made by him to ascertain what effect electricity had in mellowing wines. In reference to the note published by our contemporary in a recent issue, which we reproduced, he says:—"I made a kind of voltameter by piercing the bottom of a jar of about two litres capacity, so as to admit two platinum plates, the electrodes, which I connected to the terminals of the machine (a Gramme) by silk-covered copper wires of small diameter, but corresponding in diameter with the section of the platinum plates. Although the use of electrodes and wires of larger size gave me a more rapid action, I preferred to use small ones, because the gases, by disengaging more slowly and in less quantity, were better able to penetrate the mass of the liquid, and so the more completly to reduce the salts and acids of the wine. All having been arranged, I poured two litres of very acrid wine from Lyons into the jar, and then completed the circuit. I could not measure the intensity of the current, having no instrument for the purpose, but, according to the gas evolved at the electrodes, I estimated it at three or four ampères. After fifteen minutes I tasted the wine, as also did several other persons present, and we found it much less acrid, and more soft and mellow. I continued the experiment for another quarter of an hour, after which we again tasted the wine, and found that it had been quite transformed; it was no longer acrid, and had a mellow and agreeable taste. Its bouquet had not changed in any apparent manner. A longer period of treatment did not seem to me to add much to the results obtained in the thirty minutes. Without doubt for this quantity (two litres) this time is enough. I renewed the experiments on several occasions, and on different qualities of wines, and always observed the same effects."

RECENT INVENTIONS.

ABSTRACTS OF SPECIFICATIONS.

2492. Improvements in Electric Lamps, &c., *P. Jensen, London.—8th June,* 1881.—(*A communication from T. A. Edison, New Jersey, U.S.A.*). 8*d*.

This invention refers to a method of sealing the glass globes of incandescent electric lamps, so as to maintain a good vacuum, and is an improvement on patent No. 578, dated 10th February, 1880. The required glass having been blown into a bulb, this is broken away from the blowing rod at the tapered end sufficiently to leave room for introducing the carbons. Upon the semicircular end of the bulb a small opening is made and a tube formed thereon, by which to exhaust the lamp. A small piece of tubing is then taken, and an enlargement blown therein of a diameter about equal to the aperture above referred to in the taper end of the bulb. The leading-in wires are then laid in this tube. One end is brought to welding heat and clamped down on the wires, hermetically sealing them in the tube. The wires are in three sections, a central bit of platinum for sealing into the mass of the glass, with copper extremities, one leading from the lamp, the other into it for supporting the carbon. The end of the latter portion is flattened and wrapped round the ends of the carbon, and this union may then be electro-plated. The carbon is then introduced into the globe, and the edge of the opening of the globe and the enlargement of the tube sealed at a welding heat. The globe is then exhausted through the upper tube, and when sufficiently exhausted the latter is fused and welded near the body of the globe. The specification also describes methods for utilising defective carbons by arranging them so that the more perfect side is the negative portion; also for automatically transferring the current from one circuit to another in case of breakage, &c.

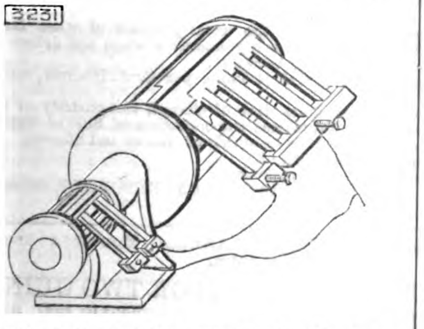
2532. Improvements in Electric Cables, *G. E. Gouraud.—10th June,* 1881.—(*A communication from P. B. Delany and E. H. Johnson, New York.*) 6*d*.

To avoid as much as possible the effects of induction the inventors form their cable of a number of insulated wires wrapped in a leaden covering. The method of construction is to take a lead pipe, flatten it out, leaving room between its sides for insertion of the insulated wires. These are then inserted so as to fill the pipe, and the latter is then passed between rolls which force the metal between the wires and fill all interstices, holding the wire in place and forming a flat cable. The wires are so arranged that at stated intervals their relative positions will be changed. Thus in a cable of six wires the order in the first section will be 1, 2, 3, &c., in the second 3, 1, 5, &c., in the third 5, 3, 6, &c.

3231. Improvements in Commutators for Dynamo or Magneto-Electric Machines, &c., *E. G. Brewer, London.—23rd July,* 1881. —(*A communication from T. A. Edison, Menlo Park, U.S.*). 6*d*.

The object of the invention is to reduce sparking; this is done as follows:—The insulation of the commutator is widened and the conducting bars narrowed at one end, and on this portion of

3231

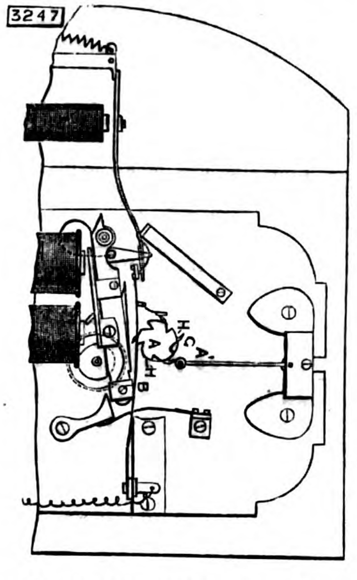


the commutator cylinder and at each side thereof a single isolated brush is arranged to bear, whose bearing end is noticeably behind the ends of the main brushes, as shown in the figure. This brush is connected to a series of breaking points resting on a breaking cylinder, as shown.

3247. Self-acting Electric Clocks, *F. T. Reid, Exeter, and J. U. Valentine, Teignmouth.—25th July,* 1881. 6*d*.

A wheel A of ivory or other insulating material carries platinum points H H connected to a brass axis A[1], and revolving with the wheel of the clock

3247



train. A has a corresponding number of large insulated ratchet teeth G, which lift the contact piece B, causing the completion of an electric circuit, which partially winds up the clock and sets a relay to work, actuating the dials.

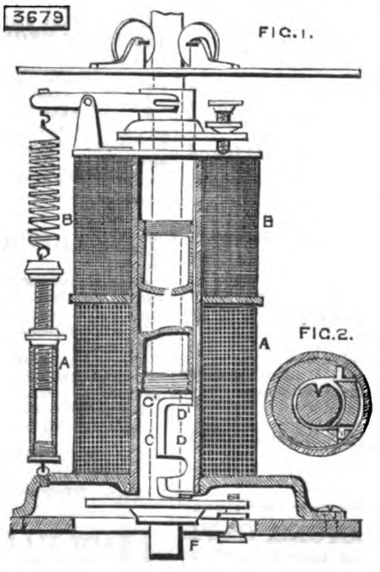
3650. Improvements in or Connected with Electric Lamps, *G. Pfannkuche, London. —22nd August,* 1881.—(*Not proceeded with.*) 2*d*.

Instead of enclosing the carbons of incandescent lamps in a vacuous globe, the inventor proposes to envelope them in a transparent body, such as glass.

3679. Improvements in Electric Light Regulators, *S. Pitt, Sutton, Surrey.—23rd August,* 1881.—(*A communication from S. J. Burrell, Brooklyn, New York.*) 6*d*.

Fig. 1 represents the regulator and upper carbon, which is movable. The action is as follows:—Core C D of coil A is in two sections. Core section C has two ears—see Fig. 2—to which lower end of section D is pivotted. The ends C[1] D[1] of

3679

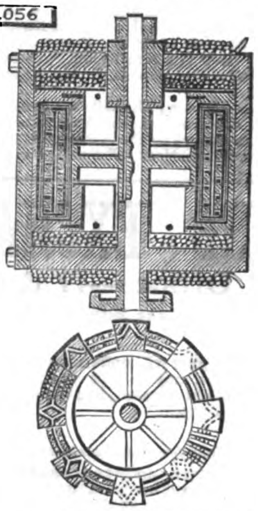


the two sections of the core being of similar polarity repel each other; this causes end of section D to be pressed against and grasp carbon F, and the whole core being also free to move upwards the upper carbon is separated the required distance from the lower one. Coil B is of thin wire, and acts as a shunt circuit for maintaining a constant resistance. The current is conducted to the carbon by the rollers shown.

254,056. Dynamo-Electric Machine, *William E. Sawyer, New York, assignor to Bernard Lande, same place.—Filed December 3rd,* 1881.

Brief.—The pole pieces of the field magnets nearly surround the cylindrical armature within and without. The armature is cast in one piece, and has air passages extending through those portions upon which the wire is wound, and having external openings in the polar extensions. *Claim.*

254.056

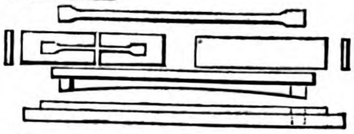


—A ring armature on the Pacinotti principle, composed of one piece of metal, and having air passages extending through the parts on which the induced conductor is wound and out at the external periphery of the polar projections, substantially as and for the purpose set forth.

254,672. Carbon for Electric Lamps, *Hiram S. Maxim, Brooklyn, assignor to the United States Electric Lighing Company, New York, N.Y.—Filed April 25th,* 1881.

Claim.—The process of manufacturing carbon conductors for incandescent lamps by first carbonising at a high temperature in flask sheets of proper material, then cutting or punching from

254.672

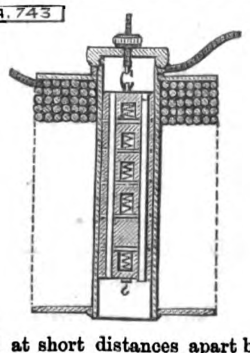


these the conductors in any desired shape, and lastly heating the said conductors in a carbonaceous gas or vapour, substantially as set forth and described.

254,743. Electro-magnet, *Addison G. Waterhouse, New York, N. Y., assignor to the United States Electric Lighting Company, same place.—Filed August 1st,* 1881.

Claim.—(1) An electro-magnet consisting of a hollow core of non-magnetic metal, having a coil or coils wound thereon, in combination with a core composed of independent sections of iron,

254.743



suspended at short distances apart by means of connections passing through the sections, which allow the sections to be drawn together when magnetised, substantially as described.

CRYSTAL PALACE.

INTERNATIONAL ELECTRIC EXHIBITION.

LAST WEEKS OF THE INTERNATIONAL ELECTRIC EXHIBITION.

The present Exhibition will CLOSE on JUNE 3rd.

This Exhibition forms the MOST COMPLETE EXHIBITION OF ELECTRIC LIGHTING EVER SEEN.

The Tropical Department is lighted by the Anglo-American Brush Light Corporation; the Roman and Mediæval Courts, and a portion of the North Nave, are lighted by the Electric Light and Power Generator Company; the Greek and Renaissance Courts, and the North Nave between, by the National Electric Light Company; the North Nave, near the Centre Transept, by the British Electric Light Company; the Handel Orchestra and Pompeian House by Messrs. Rowatt and Fyfe; the Centre Transept by Messrs. R. E. Crompton and Co.; the Concert Room and Entertainment Court by the Edison System; the North End of the South Nave by Messrs. Strode and Co.; the adjoining portion of the South Nave, the Birmingham Court, the Scientific Court, and Negretti and Zambra's Studio, by M. Gravier; the South End of South Nave by Gerard and Co.; the Railway Corridor, leading to the L. B. & S. C. Railway, and a portion of the West Corridor, by the Hammond Electric Light and Power Supply Company; the South End of Palace, by Messrs Siemens Brothers and Co.; Part of the Picture Gallery, and various other portions of the Exhibition, by Swan's Electric Light Company; the remainder of the Picture Gallery by the White House Mills Company, of New York; the Western Gallery by Messrs. G. Hawkes and Co.; the South Gallery by Mr. G. G. André; and the Opera Theatre and adjoining Avenue by the Compagnie Générale d'Electricité.

The Non-Lighting Exhibits comprise the finest collection ever brought together of Telegraphs, Telephones, Signals, Batteries, Electric Motors, Electro-Medical Apparatus, Electro-Chemical Apparatus, Cables, Wires, Lightning Conductors, Electro-Magnetic Machines, Dynamo-Electric Machines, Magnets, Electric Clocks, &c.

No extra charge to the Exhibition. The Palace Main Entrances, South Entrance, and Entrances at the Railway Stations, will be open for admission till 9:45 p.m. daily till further notice. The outlying Entrances will close at 7:30 p.m.

THE EXCHANGE TELEGRAPH COMPANY, LIMITED.

Head Offices--17 & 18, Cornhill, E.C.; Stock Exchange, E.C.; 27, Regent Street, W.

Incorporated the 28th March, 1872, under the Companies Acts of 1862 and 1867, and by Special License from H.M. Postmaster-General.

This Company will undertake to supply recording instruments, telegraphically connected with the Stock Exchange, by the aid of which Subscribers, at their respective offices, may be kept continuously advised throughout the day of the constantly occurring market fluctuations in stocks and shares.

Instruments are placed in the offices of Subscribers and kept in order by the Company, free of every expense but that of rent, and inspectors visit them daily to supply ink and paper.

Terms: £50 per annum, payable quarterly in advance.

Applications for instruments to be made to the Secretary at the above address.

Not having any springs or clockwork to wind up or to depend on, these instruments are acknowledged by those familiar with the system of telegraphy to be the only instruments yet invented that are capable of doing the work required of them continuously for a lengthened period, as evidenced by the fact that the Gold and Stock Company of New York, having the monopoly of this kind of business in the States, and which owns all the patents of the day of any value, has, after due trial, discarded all others.

The Company is prepared to treat with provincial Companies requiring instruments for the delivery of news for either single or double wire systems under the Company's patents, whereby from central stations identical information can be simultaneously delivered to any number of recipients by automatic, self-adjusting, printing instruments requiring no local batteries, no winding up, and no knowledge of telegraphy on the part of the receiver, the printing being in bold roman type, and the propulsion of the paper being effected by the electricity supplied from the Central Office.

The instruments supplied by the Company can be had to work either on single or double wires, and to print either on a slip or tape of paper, as has hitherto been the custom, or on a broad band of paper in column form.

The system has been in use by the Exchange Telegraph Company (Limited) in the City and West End of London since 1872, and by MacMahon's Telegraphic News Company (Limited), for the delivery of Parliamentary, Sporting, and General Intelligence, since 1879.

The Company will supply householders and others with its

DISTRICT CALL SYSTEM.

By the aid of a small automatic telegraph instrument a Subscriber can at any hour, day or night, call a messenger, cab, or policeman, or give the alarm of fire, and will obtain the required assistance within three minutes of making the signal. Subscribers, when absent from their homes for a season, can leave their houses closed, and have them taken charge of by the Company, and rendered perfectly secure against burglars by a telegraphic communication with the nearest District Call Station of the Company, where a policeman will always be in readiness day and night to respond to calls.

Provincial combinations to work under the Company's Patents will be treated liberally.

The Company is also prepared to supply Municipalities with its system of

STREET FIRE ALARMS

as recommended by H. M. Postal Telegraph Department to the Metropolitan Board of Works for the Metropolitan Fire Brigade, and which has received favourable mention by Captain Shaw in his last annual report.

These Alarms have recently been considerably improved by the Company, and are acknowledged to be the simplest yet constructed.

All communications to be addressed to the Secretary as above.

THE DIRECT UNITED STATES CABLE COMPANY, Limited.
ALTERATION OF TARIFF TO TWO SHILLINGS PER WORD.
"Via DIRECT CABLE."

On and after the 22nd May, 1882, and until further notice, the CHARGE for the TRANSMISSION of TELEGRAMS "Via DIRECT CABLE," between GREAT BRITAIN or IRELAND and NEW YORK and CANADA will be TWO SHILLINGS PER WORD.

The name of the place from which Messages originate will be transmitted free of charge.

For rates to other places and further particulars apply at any of the Company's offices.

J. W. FULLER,
Secretary and Traffic Manager.

General Offices, 52, Old Broad-street, London, E.C.,
13th May, 1882.

LIFE ASSOCIATION of SCOTLAND.
Founded 1838.

HEALTHY PERSONS OF ALL AGES will find in the BONUS SYSTEMS of the LIFE ASSOCIATION of SCOTLAND advantages far exceeding those which can be obtained under any of the ordinary systems.

Claims and Bonuses paid.............................. £4,028,000
Annual Revenue 436,000

Immediate Entrants in Class A will secure ONE YEAR'S BONUS MORE THAN LATER ASSURERS in that class.

LONDON—5, Lombard-street, and 48, Pall Mall.
EDINBURGH—82, Princes-street.

TO MEDICAL ELECTRICIANS, INVESTORS, CAPITALISTS.—To be SOLD, the very advantageous and long LEASE, at nominal rent, together with the whole of the FITTINGS and FURNITURE of an ELECTRIC and TURKISH BATH INSTITUTION, now continuing. An established business, and capable of great extension. The building is large, and in first-class position, and eminently suited for Public Baths, &c. Address, in first instance, "Exors.," care of H. W. Nelson, 377, City-road, London, E.C.

WORKING ELECTRICIAN WANTED, to serve in shop. Useless to apply unless thoroughly practical in all branches. State age, wage, and all qualifications by letter to R. F. H., 60, Strand, London.

THE Advertiser, having just passed through a course of practical and theoretical instruction, is desirous of an Engagement as ASSISTANT ENGINEER in any Telephone or Electric Light Company. Address P. R., 98, Queen Victoria-street, E.C.

TO ELECTRIC COMPANIES, MANUFACTURERS, &c.—The Advertiser, who has had twenty years' experience in the driving and charge of stationary engines, wishes to obtain a SITUATION. Excellent testimonials for perfect sobriety and attention to duty, seven years in his last situation, thirteen in his previous one.—G. DAY, care of J. B. WEMYSS, Esq., Stonebridge Park, Willesden, N.W.

ESTABLISHED 1851.

BIRKBECK BANK.—Southampton Buildings, Chancery Lane.

Current Accounts opened according to the usual practice of other Bankers, and Interest allowed on the minimum monthly balances when not drawn below £25. No commission charged for keeping Accounts.

The Bank also receives money on Deposit at Three per Cent. Interest, repayable on demand.

The Bank undertakes for its Customers, free of charge, the custody of Deeds Writings, and other Securities and Valuables; the collection of Bills of Exchange, Dividends, and Coupons; and the purchase and sale of Stocks and Shares.

Letters of Credit and Circular Notes issued.

A Pamphlet, with full particulars, on application.

FRANCIS RAVENSCROFT, Manager.

31st March, 1880.

The Birkbeck Building Society's Annual Receipts exceed Four Millions.

HOW TO PURCHASE A HOUSE FOR TWO GUINEAS PER MONTH, with immediate Possession and no Rent to pay. Apply at the Office of the BIRKBECK BUILDING SOCIETY.

HOW TO PURCHASE A PLOT OF LAND FOR FIVE SHILLINGS PER MONTH, with immediate possession, either for Building or Gardening purposes. Apply at the Office of the BIRKBECK FREEHOLD LAND SOCIETY.

A Pamphlet, with full particulars, on application.

FRANCIS RAVENSCROFT, Manager.

Southampton-buildings Chancery-lane

SLIP

The Telephone in Africa.—A telephone exchange has been opened at Port Elizabeth, South Africa. The lines are of steel wire.

Electric Light in Brussels.—The buffet and restaurant in the Musée du Nord at Brussels are to be lighted by Edison incandescent lamps.

The Inductophone.—We are compelled, owing to the lengthy reports in this week's issue, to leave over an illustrated article on this apparatus till next week.

Electric Lighting for the City.—At a recent meeting of the Commissioners of Sewers it was stated that eight tenders had already been sent in for lighting the new districts of the City.

Royal Society.—The following paper was to have been read before this society by Professor J. A. Ewing, of Tokio, viz.:—"On Effects of Retentiveness in the Magnetisation of Iron and Steel" (Preliminary Notice).

The Telephone in France.—M. Cochery, the French Minister of Posts and Telegraphs, has asked the Chamber for a grant of 250,000 francs to enable him to establish a State telephonic service between certain towns in France.

Electric Light in Madrid.—It is stated that the Madrid Gas Company are about to introduce the electric light as a means of illuminating the Alcala-street. Gas engines and Siemens dynamo-machines will be used to generate the current.

Electric Railway.—The examiners of the House of Lords have reported that the standing orders have not been complied with. The Bill has, therefore, been referred to the Standing Orders Committee to decide whether it is to be allowed to proceed.

Electric Lighting Bill.—Mr. Johnson, the agent here of Mr. Edison, in his evidence before the committee, has given a mass of interesting information about incandescent lighting, its cost, &c. The abstract of this evidence will be given in our next issue.

The Telephone in Newcastle-on-Tyne.—The Northern District Telephone Company, who opened a telephonic exchange in Newcastle some three months ago, have now about 120 subscribers in communication. These are chiefly resident in that part of the town known as Quayside.

Electric Light in Salford.—We believe that the Edison incandescent lamp will shortly be in use in several factories in Salford, near Manchester. Amongst others, Messrs. Platt Brothers will employ this light. The lamps and machines will be erected by the Edison Electric Light Company.

Electric Light in Constantinople.—*La Lumière Electrique* says that the large gardens surrounding the Sultan's Palace at Yildiz-Kiosk are to be lighted by electric lights. The necessary machines and apparatus have arrived, and have been tested by the officials of the Ottoman Admiralty.

Fire Risks and Electric Lighting.—The name of Mr. J. E. H. Gordon was accidentally omitted from the list of the committee appointed by the Society of Telegraph Engineers and of Electricians to consider this question, which was given in our last issue. Mr. Gordon was, we believe, the original promoter of the investigation.

Legal.—An action brought by Mr. George Twigg, of Birmingham, against the British and Irish Telephone Company for damages because of the fall of a chimney stack to which telephone wires had by permission been affixed, resulted in a verdict for the defendants, on the ground that the "wire was not the cause of the chimney falling."

South American Cables.—We are informed that the ss. "Silvertown" has safely arrived at Santa Elena with a large portion of the cable for these lines on board. The "Silvertown" will at once commence to lay her cables towards Salina Cruz, near Tehuantepic, in Mexico. The ss. "Dacia" returned from her work on the West Coast of America, and arrived at Liverpool on the 22nd inst., "all well."

Electric Light in Vienna.—We learn that experiments have been made in Vienna to decide the question of lighting the new Reichsrath buildings. The magnificent peristyle of the building was lighted from above, the light being diffused through glass. The large hall was lighted by numerous lamps, and a lustre of sixty lamps was placed in the meeting hall of the Austrian delegates. The experiments are said to have been satisfactory.

The Edison Light in Philadelphia.—A *Times* telegram, dated Philadelphia, May 19, says that Edison's incandescent light has been introduced in the composing and stereotyping rooms of the Philadelphia *Public Ledger*, and used successfully for three nights, entirely replacing gas. Seventy-four lamps are used, of 16 candle-power each; and the electricity is furnished by one dynamo mechine, driven by a special engine. Eight lamps are supplied for each horse-power.

Fires in New York.—According to the report of the New York Fire Department for 1881, there were 1,785 fires in that city during the year. Of these only four were attributed to electricity. In one case—at the Germania Theatre—the explanation given is, that the insulation of the wire running over a tinned arch above a street entrance being defective, the water of a shower led the current to the tin, it melted the solder, burnt the tin, and ignited the woodwork below.

Edison's Electric Light Meter.—In the report of the second of Mr. Day's lectures on the fire risks of electric lighting, given in our last issue, the Edison electric light meter is alluded to, in the latter portion of the report, as "Mr. Jehl's current meter." To avoid confusion we may say that the meter is the invention of Mr. Edison, and that Mr. Jehl is the gentleman to whom the experiments necessary to perfect the details of its construction were entrusted, and by whom they have been most thoroughly carried out.

Cable Repaired.—The Direct Spanish Telegraph Company announce that their direct cable communication with Spain, *viâ* Bilbao, is now restored. The repairing work was carried out by the Silvertown Company. The ss. "Oersted" was employed in the work. She left London on the 9th, but was unable to do any repairing work for four days, owing to the heavy weather in the Bay of Biscay. The fault was successfully repaired on Friday night, the 19th inst. M. A. le Neve Foster was in charge of the operations, and was assisted by Mr. A. S. Page. The "Oersted" returned to London on the 24th inst.

The Telephone Case.—In the Court of Appeal, on the 22nd instant, in the case of the United Telephone Company *v.* Harrison, Cox-Walker and Co., Mr. Cozens Hardy, Q.C., on behalf of the plaintiff company, asked that, notwithstanding that the judgment was not drawn up, the appeal, which it has been decided to bring, might be entered in the list, so that, should the state of business allow, there might be some prospect of the appeal being heard before the Long Vacation.—The application was refused, and it was stated that, until the Summer Circuits, the Court would be occupied with hearing common law appeals.—The judgment that has been

Digitized by Google

pronounced in this case will be found in another part of our issue.

The Edison and Swan Lamps.—The solicitors of the Edison Electric Light Company, Messrs. Waterhouse and Winterbotham, have written to the daily papers, stating "That the board of that company are advised that the lamp known as the Swan incandescent lamp is an infringement of the Edison patents." The solicitors of the Swan Company, rejoining in the following issue of the papers, state that "they are advised that the Swan incandescent lamp is not an infringement of the Edison or any other patent. The Swan lamp has been before the public unchallenged for a considerable time, 1,200 of the lamps having been nightly in use for several months past at the Savoy Theatre alone."

The Telephone in Collieries.—Telephones have been introduced into the Manvers Main Collieries and the Oaks Collieries, and by their means conversation can now be carried on between the officers on the surface and the workings, which are more than a mile apart. The telephone apparatus, which consists of Johnson's patent transmitter and Bell's patent receiver, with a suitable ringing alarum for calling attention, has been erected by Messrs. Tasker, Sons, and Co., of Sheffield. For colliery work the telephone has proved most useful, and the wonder is that it has not been more widely adopted. As a saver of time and labour, to say nothing of being the only means of communication with the workings in cases of accident, the telephone is pre-eminently useful.

Electric Light in Theatres.—Experiments have been made in the Monnaie Theatre at Brussels, under the supervision of a special committee appointed by the city authorities, to study the best means of preventing fires in theatres. The lamps used were on the Lane-Fox incandescent principle, supplied with current from accumulators. The cables leading from the accumulators to the lamps, and also to the charging machine, were covered with insulating material having the character of asbestos and being incombustible. The motor and machine were placed in the cellars of the theatre, the former being of six horse-power. The stage was furnished with 39 incandescent lamps as footlights, the current supplied to them being regulated by a commutator of variable resistance. This instrument permitted the light to be modified by 10 degrees, without extinction, by the successive introduction into the circuit of decreasing resistances.

Thunderstorms.—Severe thunderstorms are reported as having taken place in the early part of this week in the Midland and Western districts. A terrific storm passed over Nuneaton on Tuesday afternoon, the lightning being peculiarly vivid. During the course of the storm a horse was killed by a flash of lightning on a farm at Badersley Ensor, near Nuneaton. On the same afternoon a boy named Albert Williams was killed by the lightning at Upper Gornal, near Sedgeley. Previous to the storm he was noticed on the top of a hay rick searching for birds' nests. He was afterwards seen to be knocked down by lightning. His body was badly burnt, and his hair was singed. Other persons had narrow escapes. At Wolverhampton the lightning struck a chimney stack adjoining the Peacock Hotel, and knocked it down. No one was injured, though the bricks fell into a room full of people who were dining at the Hotel. Severe storms are also reported as having passed over Cheshire and Holyhead.

Legal.—The case of the Midland Electric Light Company *v.* the Brush Midland Electric Light and Power Company was heard on Friday, the 19th inst., before Mr. Justice Chitty. It was a motion for an injunction to restrain the defendants from using the name of the Brush Midland Electric Light and Power Company, or any other name identical with or so nearly resembling the plaintiffs' name as to be calculated to deceive or mislead. The plaintiffs, whilst allowing that there was no intention of fraud in the defendants' adoption of their name, contended that the word Midland was the keystone of the name which had priority of registration, and that its presence in the defendants' name had, in fact, produced confusion between the two companies. —His lordship, without calling on the defendants, said that confusion between the two names could not arise in the mind of any person in possession of his senses. The plaintiffs' case failed altogether, and the motion must be dismissed with costs.

The Patent Laws.—In a leading article on the telephone case, *The Times* makes some allusions to the present state of the law relating to patents in this country. The article in question concludes as follows:—"It will hereafter be looked upon as a disgrace to our generation that inventors should be taxed to the extent which our present patent laws permit. They are a class to which the country owes much of its prosperity, and yet we withdraw enormous sums from their pockets, which are often the pockets of poor and struggling men, merely to give them a nominal and delusive property in the creations of their own brains, a property which amounts to little more than the right to defend themselves in a court of law if they are attacked. The demand is urgent for a reform by which patents will be granted with discrimination, by which the fees will be reduced to the lowest point compatible with the working of the necessary machinery, and by which some means would be provided of bringing disputes touching infringement under the cognizance of an inexpensive and a competent tribunal." The shadow of coming events makes these words of great interest to inventors in the electrical world.

The Telephone and the Post Office.—In the House of Commons, on Friday, the 19th inst., Mr. R. Martin asked the Postmaster-General when he would be able to state the conclusion at which he might have arrived as to granting a license to the London and Globe Telephone Company, authorising them to work in London and its suburban districts; and whether he had any intention of purchasing the business of one particular company at a large price, and thereby creating a monopoly of telephone service, by which the public would be deprived of the benefit of a helping competition in the development of a scientific invention, which might still be considered to be in its infancy.—In reply Mr. Fawcett said that he had received applications, not only from the London and Globe Telephone Company, but from other telephone companies for licenses to carry on business in various towns, where a telephone exchange is already established, either by a private company or by the Post Office. He was not yet in a position to announce his decision, but he could assure his hon. friend that there should be no unnecessary delay in arriving at a conclusion, and in making it known. He also stated that the Government had no intention of purchasing the business of any telephone company.

International Congress of Electricians.—*L'Electricité* says:—"The greater portion of the political papers have made the mistake of announcing that a congress of electricians would be held in Paris on the 1st May, 1882. We are in a position to state that there will be two distinct congresses. The object of the first will be to give force to the decisions of the congress of electricians (presumably the one held in September last), and the second to

Digitized by Google

adopt international measures for the protection of cables. These two congresses are perfectly distinct from one another, and although both are convened by the Minister for Foreign Affairs they will take place at two different times. The same papers are also in error in giving the date of the meeting of the congress as the 1st of May. We can affirm that the 1st of June is the only date that has been spoken of in connection with the congress on electrical units. We do not think that the congress on the question of the protection of cables can be opened before the 1st of October, owing to the preparations which are now being made by the various Governments in order to formulate the instructions to be given to their representatives." *L'Electricien*, on the other hand, states that the congess on the question of electrical units will not be held until the 1st of October.

New Companies.—The following new companies have been formed:—The British Insulite Company, with a capital of £250,000, to work the patents of Dr. J. A. Fleming for a new material called insulite, and which is designed to supply a cheap and efficient insulating material. Mr. Latimer Clark is amongst the directors, and Mr. J. Hopkinson, F.R.S., is consulting electrician. The company's offices are at 44, Gresham-street, E.C., where the material can be seen.—The Duplex Electric Light, Power, and Storage Company is announced, with a capital of £100,000. It has been formed to work the patents of the "Duplex" system of electric lighting. According to the prospectus a combined generator and storage battery has been devised, which can be charged by hand and used for incandescent lamps.—The Yorkshire Brush Electric Light and Power Company, with a capital of £300,000, has secured a concession for the county whose name it bears from the Hammond Company, which includes the Brush machine and lamp, and the Lane-Fox lamp.—The Jablochkoff Electric Light and Power Company has a capital of £300,000, and is formed to work the Jablochkoff light and machine, and the Gatehouse automatic light changing apparatus. An agreement has also been entered into with the Electric Light and Power Company, by which that Company will supply the Jablochkoff Company with Maxim incandescent lamps.—The Swan United Electric Light Company has been formed to acquire the business of Swan's Electric Light Company, with its patents, &c., including the license to use the patents of Messrs. Swan and Sellon for the storage of electrical energy. An arrangement has also been concluded with Messrs. R. E. Crompton and Co., by which the company have acquired all their existing lighting contracts, and the right to the services of Mr. Crompton and his firm, together with the right of supplying his arc light. Mr. Swan and Mr. Crompton will join the board of the company after allotment as technical directors.

Subdivision of the Electric Light.—Mr. W. H. Preece, F.R.S., writes to *The Times* as follows, with reference to a recent statement made by Mr. Spottiswoode that a committee of the House of Commons had declared that "the subdivision of the electric light was not to be hoped for." Mr. Preece says:—"I think he must have had in his mind my evidence, which was to that effect; for the committee made no such remark. My statement was and remains strictly true. There is great confusion between the problem of the subdivision of the electric 'light' and that of the distribution of the electric 'current.' They are two totally different questions, which are generally mistaken for each other. If a given current, say that equivalent to one-horse power, will give a light, say of 2,000 candles, you cannot by any known means divide that light into twenty lamps of 100 candle-power each. The best that has hitherto been done from one horse-power is to obtain eight lamps of 16 candle-power each. You can, however, distribute the current in any way you please. If one horse-power will give you one lamp of 2,000 candle-power, or eight lamps of 16 candle-power, it is evident that 2 horse-power will give you two lamps of 2,000 candle-power and sixteen small lamps; 3 horse-power, three lamps of 2,000 candle-power or twenty-four small ones, and so on, directly by multiplication and distribution. Mr. Brush has shown how to multiply his lamps, and Mr. Edison has shown how to distribute his currents and multiply his lights, but no one has as yet attempted to solve the question of the subdivision of the electric light. The largest machine yet made, that of Edison, will maintain 1,200 incandescent lamps, giving 16 candle-power each, or a total light of 192,000 candles, with an expenditure of 150 horse-power. Such a power applied directly to the production of light ought to give a light of many million candles. Although I still maintain that the useful subdivision of the electric light is not to be hoped for, it is not to be assumed that I or any one else opposes the distribution of the electric current and the multiplication of electric lamps. This is now practically and economically within the reach of all."

Dimensions of a Magnetic Pole in the Electrostatic System of Units.—In the *Philosophical Magazine* for May Professor J. D. Everett gives the essence of a paper by Clausius, dealing with electrical and magnetic units. He says:—"Electricians are familiar with the fact that a circuit with a current flowing in it is a species of magnet, and that the moment of the magnet thus constituted is the product of the current by a certain area. Hence the moment of a magnet must have the same dimensions as a current multiplied by an area. That is, we must have Pole × Length = Current × (Length)^2; or, more simply, Pole = Current × Length. This equation must be true in any consistent system of units. In the electrostatic system, the dimensions of Current (or quantity of electricity divided by time) are $M^{\frac{1}{2}} L^{\frac{3}{2}} T^{-2}$ (M denoting Mass, L Length, and T Time). Hence, by the above equation, the dimensions of a Pole are $M^{\frac{1}{2}} L^{\frac{5}{2}} T^{-2}$. This is substantially Clausius's reasoning, though I have for brevity somewhat altered its form; and it appears to me unimpeachable. Nevertheless, the result differs (as the author points out) from Maxwell's formula for the dimensions of a pole in the electrostatic system, namely, $M^{\frac{1}{2}} L^{\frac{3}{2}}$. This formula will be found in Maxwell's 'Electricity and Magnetism,' § 626, where the name 'quantity of magnetism' is used instead of 'strength of pole,' or the briefer name 'pole.' It will also be found in the reprint of 'Reports of the B.A. Committee on Electrical Standards,' page 90; but in neither work have I been able to find an explicit statement of the reasoning by which the result is obtained. Perhaps some reader of the *Philosophical Magazine* can give the necessary explanation. In my own treatise on 'Units' the question at issue is not raised, as practically the dimensions of a magnetic pole do not enter into electrostatic discussions. The dimensions of a pole, calculated in the ordinary way from the mutual repulsion of two poles, are $M^{\frac{1}{2}} L^{\frac{3}{2}} T^{-1}$; and from this, by considering the force exerted by a current upon a pole, the dimensions of Current in the electro-magnetic system are found to be $M^{\frac{1}{2}} L^{\frac{1}{2}} T^{-1}$. The relation between these two, it will be observed, fulfils the foregoing condition, Pole = Current × Length. It appears to me that Clausius's result must be accepted as the correct one." The editor of the *Phil. Mag.* announces that a full translation will be given in an early number thereof.

Digitized by Google

AN ELECTRIC RAILWAY IN THE BLEACHING GROUND.

To the many industries which are indebted to electricity as a motive power must be added that of bleaching. In the particular instance under notice, electricity has been made use of to the exclusion of steam on account of its cleanly properties, if we may so call them. For obtaining motive power by means of steam it is impossible to prevent the production of smoke, and smoke in a bleaching ground, to say nothing of cinders and sparks, would be likely to injure seriously the material bleached. Consequently, if motive power is required, it should be supplied by an agency which produces no smoke, and no cinders. Electricity is exactly the agency required.

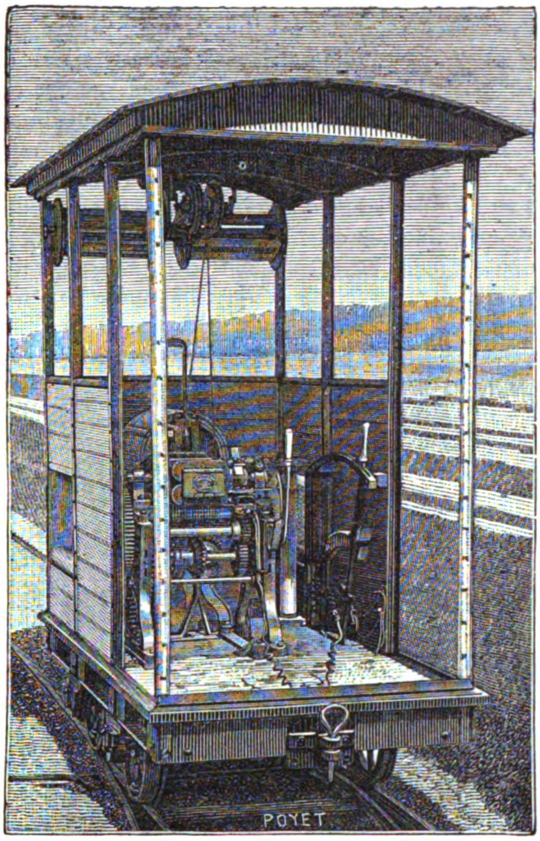

Fig. 1.—The Locomotive Car.

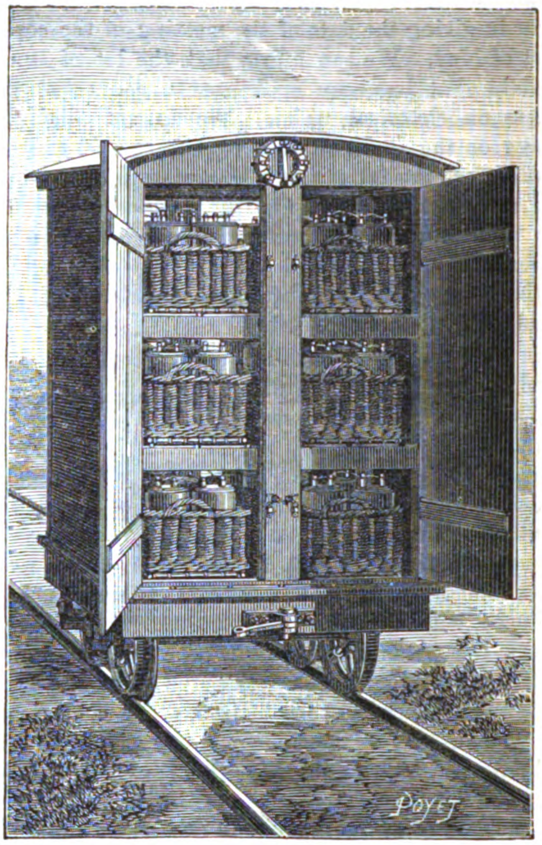

Fig. 2.—Tender carrying Faure Accumulators.

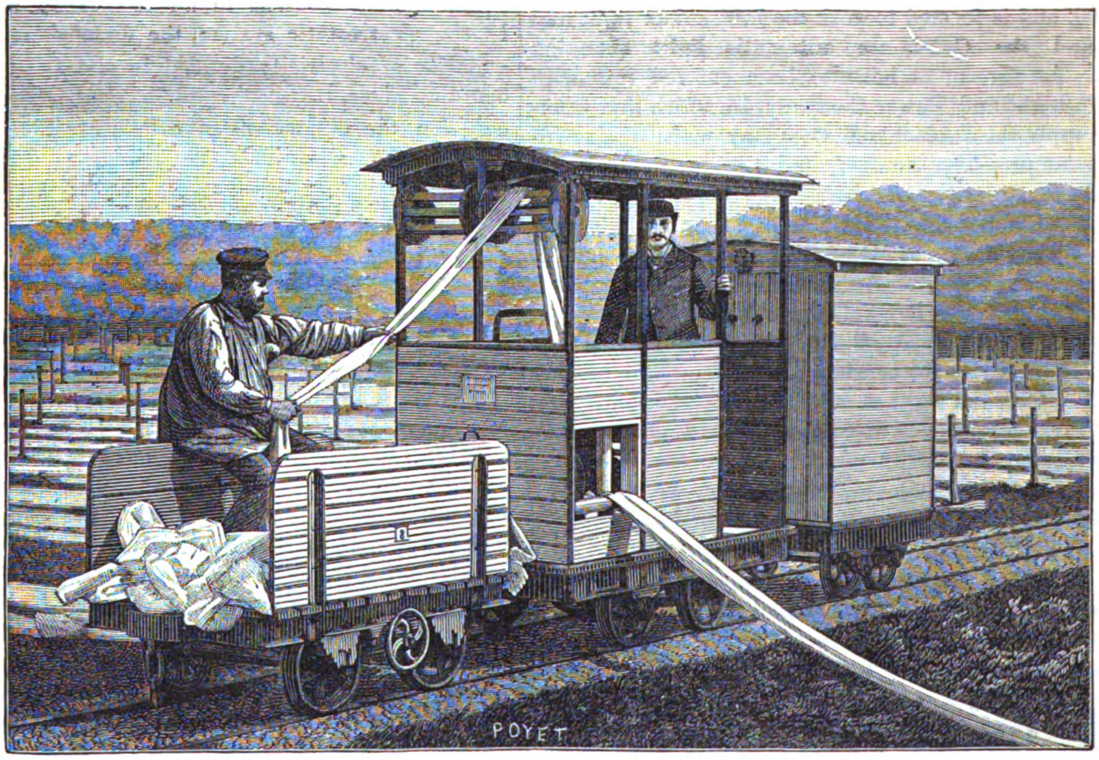

Fig. 3.—Showing the Mode of Hauling In, and also the Bleached Material.

The following account of the way in which electricity has been used to propel a train of waggons in a French

bleaching ground is taken from our contemporary *La Nature*:—

"The bleaching ground belongs to M. Paul Duchesne-Fournet, and is situate at Le Breuil-en-Ange. The establishment is a large one, and is controlled by the engineer-in-chief, M. Clovis Dupuy. The operation of bleaching consists of first treating the material chemically, and afterwards submitting it to the action of the solar rays in pieces or strips of 100 metres long. There are 15 hectares of ground, which are used for the laying out of these strips, so that the operation of taking them up after they have been sufficiently bleached is a lengthy one, and necessitates many workmen.

"The idea of gathering in these strips by special machinery carried on a railway suggested itself to M. Dupuy, but was rejected on account of the smoke and cinders which would be a necessary accompaniment of a steam engine. He then determined to try an electric railway, and accordingly constructed and worked the one we are about to describe.

"The train, which is set in motion by dynamo-electric motor (Fig. 1), actuated by Faure accumulators (Fig. 2), starts from the factory with empty waggons. When it has arrived at the bleaching ground it is brought to a standstill; the dynamo sets in motion the hauling-in machinery, between the rollers of which the end of the first strip of material is placed. The material is drawn in by the windlass rollers, passed over another roller in the top of the framework of the engine car, and thence to the waggon next it, where it is received by a workman and coiled or packed (Fig. 3). The further to save time, all the strips of material in a certain section of the ground are united to one another by their ends, so that one man can collect 5,000 metres of material in 30 minutes, a quantity which, under ordinary circumstances, it would have taken eleven hours to gather in.

"Fig. 4 shows the train fully loaded returning to the factory with 10,000 metres of material. We may now go into the details of the machinery.

"The motor, or locomotive (Fig. 1), consists of a reversible Siemens machine. A lever (Fig. 1 and Fig. 5), serves to start and govern the machine. In the vertical position shown in Fig. 5 the brake is on, and no current can pass to the machine. By lowering the lever contact is made, the rheostat chain (Fig. 5) is more and more extended, and the links make better contact, thus diminishing the electrical resistance and increasing the speed.* The speed of the train is thus varied according as the lever is moved in one direction or the other; when the lever is in the position of rest it at the same time applies the brake. A second lever is provided for reversing the direction of the train by acting on the brushes of the dynamo machine. A third lever enables the motor to be put in connection with the axle of the driving wheels, or with the machinery for winding in the material.

"A tender, attached to the engine car, carries Faure accumulators, large size, constructed by M. Reynier. They are

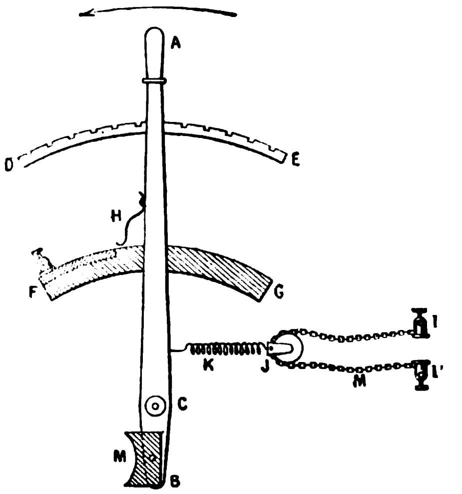

Fig. 5.—The starting lever A B C is the lever arm working between the two guides of the sector D E; F G a wooden sector carrying two contact plates, in connection with the cells; H a spring contact-piece; I J I' a rheostat chain influencing the general circuit. This chain passes over J, which is connected to the lever by a spring, K. M is the brake-shoe; C is the axis of the lever.

arranged in three rows (Fig. 2), in baskets, each of which holds six cells; there are four baskets in each row, excepting the third, which only contains two. Thus there are altogether sixty cells, weighing 500 kilogrammes. The weight of the locomotive is 935 kilogrammes, of the tender 700 kilogrammes, and of each waggon, filled, 800 kilogrammes. The cells are charged by a Gramme machine, which has been used since 1879 to give the current for the eleven Reynier lamps which light the factory. The horse-power available is 60. Three of this only is used during the charging of the batteries, which takes from five to eight hours.

"At the upper part of the tender is a commutator (Fig. 2), which permits the cells to be used in succession, beginning with a minimum of twenty-four, and increasing successively by six at a time, up to sixty.

"The railway as described has been at work for seven weeks or more, with advantageous results. The speed attained is 12 kilometres per hour, but in this particular instance great speed is not sought after or required. The time during which it can be worked is, according to the data of M. Clovis Dupuy, three hours, this time being limited by the charge of the cells."

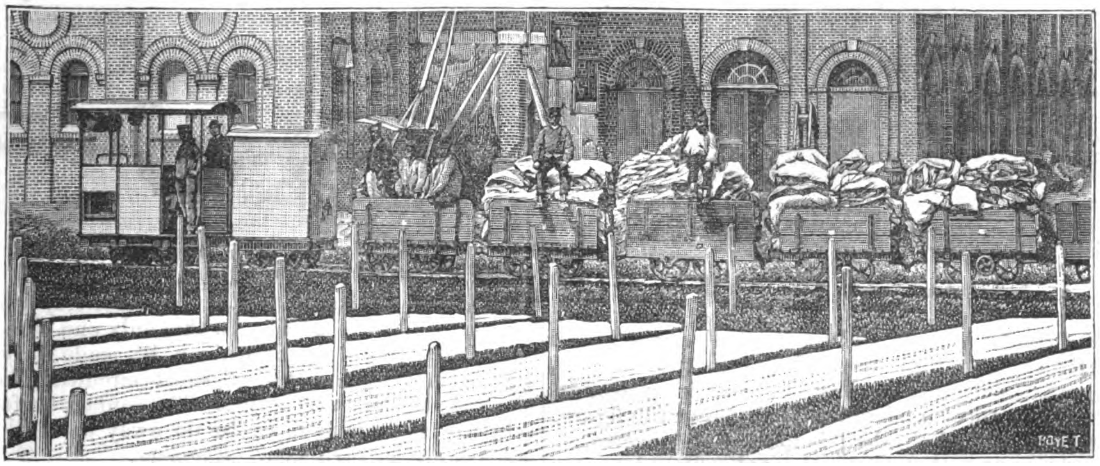

Fig. 4.—Showing the Loaded Train returning to the Factory.

* This rheostat chain was invented by M. E. Reynier, who applied it to a sewing machine which was shown last year at the Paris Electrical Exhibition.

West India and Panama Telegraph Company.—The estimated receipts of this company for the half month ended the 15th May amounted to £3,237, as compared with £2,766 in the corresponding period of 1881. The January receipts, estimated at £4,856, realised £5,039.

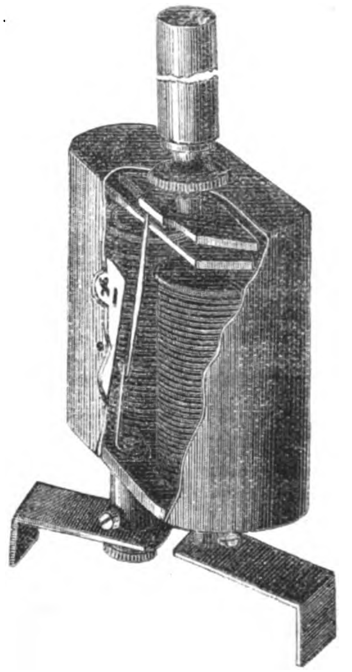
A BATTERY CURRENT TESTER.

The figure represents an apparatus which has been constructed by MM. Barbier and Pieret to enable battery cells to be readily tested, both as to whether they are giving off any current, and the character of the current. The apparatus is composed of a metal cylinder, which serves at the same time as a bell and a covering for the magnets, &c , inside. A handle at the upper part permits the two lower ears to be fitted to the poles of any cell that may be required to be tested. The electro-magnet in the interior attracts an armature, to which



A Battery Current Tester.

is fixed a small hammer which strikes the bell at the back; the interruption of the current is produced by the displacement of a small plate in the shape of a spring placed in the front of the apparatus, and which is shown in the figure. According as the sound of the bell is loud or the reverse, so the strength of the current can be estimated. The character of the current, whether positive or negative, is indicated by the appearance before a small hole in the cylinder of a steel plate with the + and − sign painted on it. This plate is so arranged as to be attracted by either magnet, and at the same time to cause the + or − sign, according to the character of the current, to appear.

BREWTNALL'S PATENT COUPLINGS FOR ELECTRICAL PURPOSES.

The accompanying engravings illustrate a new and simple coupling, invented and patented in England and abroad by

FIG.1

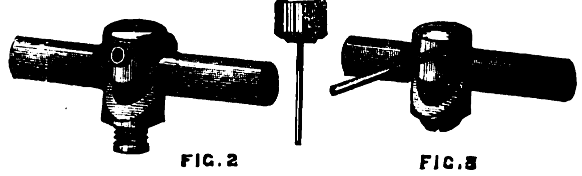


FIG.2 FIG.3

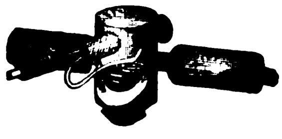
Mr. A. W. Brewtnall, for connecting branch wires with main electric light leads, which will be of especial use in fitting incandescent lamps. The couplings consist of a small brass cylinder, one end of which is solid, and the other fitted with a broad screw or nut, as shown in Figs. 1 and 3. A slot is cut in the side at an angle of about 45 deg. and long enough to receive the main wire or cable. Intersecting this a hole is drilled, either longitudinally or tranversely, to receive the branch wire. When the wires are put in their respective positions, and the screw or nut is tightened up, the main wire or cable is jammed forcibly against the branch wire and against the solid end of the slot. This gives a very firm and enduring contact between the two wires or conductors, and the surface contact is large, thus ensuring perfect electrical conductivity. A fusible portion can also very easily be combined with this form of connector, as shown in Fig. 4, which is an obvious advantage.

These couplings furnish a rapid, easy, and absolutely reliable means of connecting up wires, and entirely supersede the old method of soldering. No tool or material of any kind is required, save a screwdriver and the usual knife or instrument for cleaning the insulating matter off the wires. They

FIG. 4



are supplied at a very moderate cost by Messrs. Faraday and Son, Berners-street.

Fig. 5 shows a new form of ball-and-socket joint to be used

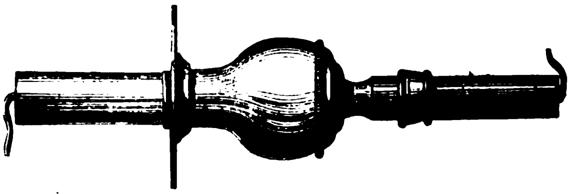


FIG. 5.

with electrical chandeliers, or "electroliers," also introduced by Mr. A. W. Brewtnall. In this only one wire need be used for the lead, and the return can be made through the outer tube without any chance of short circuiting, however much the "electrolier" may swing. The contact surfaces are large, and are so arranged as to do away with all possibility of "sparking" or corrosion.—*Engineer.*

THE CEYLON TELEGRAPH DEPARTMENT.

The greatly improved working of the local telegraphs has lately been the subject of general remark. This improvement is more especially realised by the press in the earlier receipt of Reuter's messages of public news. Up to a short time ago these daily messages seldom came to hand before 6 p.m.; but now a telegram delayed later than that hour is the exception rather than the rule. As a consequence we are able to pass our evening issue fully made up for the press by that time (6 o'clock), and the complaint about late delivery in town should be a thing of the past, if only Sinhalees delivery peons can be made to do their duty.

This is, however, by the way. We have been inquiring about the telegraph improvements, and learn from the director that the second (public) wire recently established between Colombo and Kandy enables the department to work with Paumben direct, almost throughout the day, and to avoid anything like serious delay in the exchange of messages with that station. On Wednesday last, for instance, the maxima and minima message traffic returns were:—

Minutes.	Minutes.	
88	41	Calcutta
130	43	Bombay
76	32	Kurrachee
36	10	Madras

For some time before the second wire came into use, the speed of working had been accelerated considerably, but the additional facility acquired when this second wire is hung between Matale

Digitized by Google

and Mannar will entirely put a stop to delays in transit, and the Colombo public will then practically receive their messages almost immediately after the time at which they reach Paumben. At present the traffic of Jaffna, Mannar, Anuradhapura, and Trincomalee, with other stations, has to pass over the same line, so slightly hampering the through work with Paumben. This, as we have said, will shortly be removed. The reconstruction of the line from Colombo to Kandy being now finished, the new line of three wires between Kandy and Matale along the railroad is the work in hand, and this will be disposed of by the end of April. Colombo railway terminus and the Kandy station are now in direct communication by a special wire just hung for the convenience of the traffic manager in working his up country railway lines. Altogether there are now four lines between Colombo and Kandy, two public and two railway wires. There is also the wire between the Colombo breakwater and Mahara quarry. Between Colombo and Kalutara there are two wires, one for the railway, the public one being prolonged to Galle. The line to Kurunegala has been created in pursuance of the policy which has placed each seat of provincial administration in communication with the central Government, and it is now finished, and a public telegraph office will be opened at Polgahawela station and at Kurunegala in the course of this month.

Between Kandy, Gampola, and Nawalapitiya, double wires are, of course, hung—for public and railway use—and we have no doubt this duplicate system will be carried along the railway course to Nanuoya and Haputale, so giving public telegraph stations ere long at Hatton (and probably one at Wattewella), Talewekelle, Nanuoya, Haputale Pass with branch wire extensions doubtless to Haldumulla and Badulla, as well as to Nuwara Eliya from Nanuoya.. The single wire from Gampola at present passes through the Mountain Sanatarium to Badulla and Batticaloa. Colombo and Batticaloa and intermediate stations work direct through Kandy, and this line is only "broken" (interrupted) when Nawalapitiya has to receive or send a message.

Altogether we may congratulate the colony, at a time when a "dead-and-alive" system of routine marks so many of the departments of the present Government, on the activity and progress displayed in our telegraphs under Mr. Skinner's direction, well seconded by his able lieutenant, Mr. Hurley. The island lines are now all in good working order, well insulated, and the instruments used are giving satisfaction. We have no doubt that further improvements, such as the amalgamation of telegraph and post office at out-stations, so as to enable every central post-station to have a wire, will be in due time carried out. Wherever the railway goes, as we have said, the wire, both for department and public use, is bound to follow. The present district post offices will, doubtless, in many cases be removed to the railway stations and utilised for both post and telegraph. When the wire reaches Haputale, the only extension of importance that will remain for the Ceylon Government to carry out is one thence to Ratnapura and across through Rakwane to Matara and Galle so as to give duplicate communication. But now that the mail steamers are moved from Galle to Colombo, it is doubtful if this will be required, and Matara and the stations beyond (if the telegraph should be required by them), can well be served by an extension from the present Galle line.—*Ceylon Observer*, April 12.

THE TELEPHONE CASE.

After a long trial judgment has been delivered in this case. The plaintiffs were the United Telephone Company (Limited), and the defendants, Messrs. Harrison, Cox-Walker, and Co.

The judgment of Mr. Justice Fry was as follows :—In this case the evidence on both sides has been of great extent and interest, the instruments which are in controversy are of the highest ingenuity and value, and the questions that demand decision are of considerable perplexity and delicacy.

The plaintiff sues on two patents—of these, the first that I shall refer to as the Bell patent, was granted on the 9th of December, 1876; the second, which will be referred to as the Edison patent, was granted on the 30th July, 1877. The defendants have, as is admitted, made and sold three instruments which are in question; first, a receiver, known as the Cox-Walker receiver, which is alleged by the plaintiffs to be an infringement on the Bell patent; secondly, another receiver, the Hickley, likewise alleged to be an infringement of the Bell patent; and, thirdly, a transmitter known as the Hunning, alleged to be an invasion of the Edison patent. Long before the year 1876, in fact about fifty years ago, discoveries had been made by Faraday in electricity and the connected sciences, which undoubtedly lie at the bottom of the present inventions. The substance of those discoveries I take to be fairly stated in the specification to Bell's patent when he says :—"It has long been known that when a permanent magnet is caused to approach the pole of an electro-magnet a current of electricity is induced in the coils of the latter, and that when it is made to recede a current of opposite polarity to the first appears upon the wire. When, therefore, a permanent magnet is caused to vibrate in front of the pole of an electro-magnet an undulatory current of electricity is induced in the coils of the electro-magnet, the undulations of which correspond in rapidity of succession to the vibrations of the magnet, in polarity to the direction of its motion, and in intensity to the amplitude of its vibration, or, rather, to the velocity of its motion." That invention of Faraday was, as we know, one of the most pregnant of modern discoveries. It had long been known that a vibrating metal tongue or reed could be used to make and break the contact of a galvanic circuit, and thus produce an intermittency in the current, and that similar vibrations caused by the successive presence and absence of the magnetic attraction be reproduced in another metal tongue or free reed; and the idea soon suggested itself that if the first tongue were so vibrated as to produce sonorous undulations similar results could be produced at distant places wherever the current was carried. This was the principle of the musical telephones which existed before 1876, and which in certain cases were found, occasionally and uncertainly, to reproduce vocal sounds with musical ones, especially vowel sounds.

An inventor, the German Reis, had gone a step further and used a membrane to set a piece of metal in motion, but according to the evidence before me, it is clear that before Mr. Bell's discovery there was no practical and trustworthy mode of transmitting articulate sounds to a distance by means of electricity. Mr. Bell appears to me to have seized three ideas. In the first place he distinctly perceived that whilst for musical notes the tongue or free reed might act both as transmitter and as receiver, for the human voice you must employ an extended and elastic surface, such as a disc of metal or a membrane extended and attached to a circumference, after the fashion of the drum of the human ear; and, secondly, that whilst for musical notes intermittent currents might be used, the undulations of the human voice could be communicated only by continuously undulatory currents; thirdly, that it is not necessary for the purpose of communicating the human voice to use a battery current, but that an undulatory current adequate to this purpose may be produced by placing two permanent magnets surrounded by coils, one in the transmitter and the other in the receiver, and operating on one of these by the vibrations of a plate of inductive properties placed within the magnetic field. This vibratory action of the plate produces the undulatory current which operates through the permanent magnet of a receiver on another plate of inductive properties placed within its field.

In or before the end of 1876 Mr. Bell had made an instrument which, in the first place, appears to have had a transmitter and receiver of the same character, each of those instruments consisting of a tympan or drum of membrane, which tympan or drum carried a piece of iron at an armature capable of producing inductive action; the receiver appears to have been constituted in the same way, and he appears, in the first place, to have used an instrument of that construction; but in August, 1876, at the Exhibition at Philadelphia, he exhibited an instrument made after a somewhat different fashion, in that the transmitter consisted of a membrane charged with an armature, a piece of steel spring, but the receiver was an annular magnet, furnished with a flat plate by way of armature—the external circuit, the annulus, in fact, of the magnet being one of the poles, and the central core being the other pole; and it appears to me to be clear as exhibited at Philadelphia that the armature was not attached in any way, in any physical or mechanical manner, to the body of the receiver, but that it was held down by the force of the galvanic current which passed through that receiver. Sir William Thomson visited the exhibition at Philadelphia, and naturally attended with the utmost interest to the instrument there exhibited by Mr. Bell. It appears to have answered to a certain extent in Sir William's presence, and he undoubtedly heard words brought from a distant room to that receiver. The discovery, of course, was one of the greatest interest to him, and when he was leaving Boston Mr. Bell placed in his hands a brown paper parcel which contained a transmitter and a receiver, which has been produced in Court, and which have been the subject of a vast amount of discussion. When Sir William Thomson opened that parcel he found that the armature of the receiver was attached to the annulus of the magnet by a screw, and, according to the conclusion which I arrive at, on the evidence, he found the armature tilted at a certain angle from the plane of the top of the receiver.

Sir William Thomson brought these instruments with him to this country, and at the meeting of the British Association which took place in September of that year at Glasgow he exhibited those instruments, and made them the subject of a portion of his address as the vice-president of one of the sections. The words of his discourse have been in evidence before me; they contain a statement of the results which have been arrived at by Mr. Graham Bell, but do not in my judgment communicate to the public the exact method by which those results were arrived at. It will be necessary for me hereafter, considering the objections made to the patent, to consider more in detail the fact of Sir William Thomson's exhibition of those instruments in Glasgow. I mention them now merely as part of the narrative of the case. On the 9th of December, 1876, the letters patent which are first in question were granted to Mr. Morgan-Brown on the communication made by Mr. Bell to him, and those letters patent were the subject of a disclaimer and memorandum of alteration which was filed, I think, on the 13th of February, 1878. The specification as originally filed contained five or six distinct plans of operation; with regard to the first three it is not necessary for me now to say anything more than to observe that they related to what has been called multifold telegraphy, and that they provided for the transmission of several currents along one wire or system of wires. They are not retained in the disclaimed patent except so far as they are necessary to the explanation of the fourth and fifth plans there contained. Speaking briefly, the fourth plan mentioned in that specification provides for the transmission of the human voice, by means of a continuous voltaic current; it provides for a transmitter with a membranous tympanum and a conductive armature; it provides for a similar receiver, and it also adds as an alternative plan the use of metal plates or other conductive substances. The fifth plan is founded on the discovery which I have already mentioned as having been made by Mr. Bell—in that plan the battery is omitted, and the permanent magnets are substituted for the electro-magnets in the last plan, and the current produced by the vibrations is not superimposed upon

Digitized by Google

a voltaic current, but is itself used to create corresponding vibrations in the receiver. A subordinate feature is also described which is really a description only of an electric equivalent in that form. In place of the permanent magnet you find electro-magnets in a secondary or electrical circuit, and not therefore operating upon the generodes in the main current as in the fourth plan—those two plans which form the fifth are in fact for electrical purposes one and the same. It is impossible to doubt the beauty, or the value, or the ingenuity of the discovery that had been so made by Mr. Bell—he had solved one of the most difficult problems of physics, one which undoubtedly had been attracting the attention of men of science for many years past. It was, however, found that the membrane used in the tympan was not entirely successful; in the first place that membrane had, as I have already observed, attached to it an armature—a piece of steel wire—and the presence of that weight at a particular portion of the tympan seems, according to the evidence before me, to have had some disturbing influence upon the action of the tympan itself. Furthermore, the membrane is liable to be influenced by changes of atmosphere and by the difference of moisture in the atmosphere, and was much as the receiver might be at a considerable distance from the transmitter. It is obvious that different atmospheric influences might operate on the two instruments, and therefore place them not in harmony, but in discord. Those difficulties in the way of the use of the membrane induced Mr. Bell, in the memorandum of alterations to which I have already referred, to point out that a great improvement had to be introduced into the instrument by substituting for the membranous tympan a metal plate or metal disc, which, of course, was inductive in its own nature, and was free from the objections which were found to obtain in the case of the membrane. That, as a whole, the instrument disclosed by the letters patent was new appears to me not to be doubted. What had been done only occasionally and ill before by such instruments as those of Reis, which has happened to communicate speech by intermittent currents; what Sir William Thomson himself could not do with the Glasgow transmitter and receiver—because although anxious to exhibit that instrument to the British Association at Glasgow, he had been unable then to show that it could work—what Dr. Muirhead, a witness before me in the course of this trial, could not do in his attempt to copy Sir William Thomson's instrument, that could be done as soon as the complete specification was made known. That the Glasgow instrument, taken as a whole, was incapable of producing this satisfactory result is proved to me by the fact that it failed in the hands of perhaps the most skilful person in the world to deal with such an instrument—Sir William Thomson himself.

It remains, however, to inquire whether the other instrument alone is claimed, or if not, what parts were claimed, and whether the parts so claimed were new, and whether the invention had been infringed by the defendants.

The defendants have used and sold instruments known as the Cox-Walker and Hickley receivers, and no argument has been addressed to me to show that they are not in substance the same as the Bell receiver; but the difficulty which the defendants present to the plaintiffs' case takes the form of an alternative argument. If, say the defendants, you claim only the receiver in combination with a transmitter like Bell's, we have not infringed, for we have never used such a receiver; if, on the other hand, you claim the Bell receiver as a substantive and independent invention then it is not a new one. There is no evidence of the user of the Cox-Walker or Hickley receiver, with an instrument like the Bell transmitter, and, in fact, it does not appear to have been so used. That Bell's specification claims the receiver he there describes as a substantive invention is the common case both of plaintiffs and defendants, and is also in accordance with my own construction of the specification. Has Bell's receiver, then, been anticipated by previous inventions or by public knowledge? Before considering the anticipations, I think it expedient to describe Bell's receiver as claimed by him, and as I understand it, it consists of a horse-shoe magnet, the ends of which are brought into the circuit by means of coils of wire, and in front of which is a metallic plate, capable of inductive action, placed at right angles to the length of the magnet, resting as regards its circumference on the wooden case. The vibrations in this plate are the source of sound in the receiver. In Bell's instrument the receiving and transmitting instruments are interchangeable, and the fourth and fifth plans both, in my judgment, describe an apparatus in which there are such instruments as I have described used for both these purposes.

The anticipations relied on are the first and second instruments made by Reis, or described by Reis, and the publication of Bell's own earlier plans through Sir William Thomson. Now, with regard to the instrument which has been called the first Reis, it appears to me to be made out plainly in the evidence that it was known in this country before the patent was taken out, but there is no pretence of a plate armature being used in that instrument. The machine depends for its operation on the repeated making and breaking of the currents, and upon the fact that the rod of iron included in the coil of the receiver gives a distinct tick each time it is demagnetised. The repetition of these ticks is made to produce the vocal sound. The essential parts, therefore, it appears to me, of the Bell receiver, are not in any way to be found in the receiver of the first Reis.

With regard to the second Reis, which is the instrument described in Mr. Legat's paper, in the "Zeitschrift" of the German and Austrian Telegraph Union, two questions arise. The first is, was it so published as to be part of the public knowledge on this subject before the taking out of Mr. Bell's patent? The only book in which an account of this is said to have been published is the "Zeitschrift," to which I have already referred, which is, of course, in the German language. It contains, however, two plates, the one describing the transmitter, and the other receiver, and I think it would be difficult for a person looking at those plates, and having any knowledge of magnetic or electric science, not to come tolerably clearly to a conclusion as to what the object of the instrument was. It appears that the book was deposited in the usual manner in the Library of the Patent-office, and also in the Library of the Institute of Civil Engineers; but in the latter case it was catalogued as a journal, and, somewhat strangely as it appears to me, was not catalogued either under the head of electricity or magnetism, or any kindred subject; but it is to be borne in mind that this paper is to be found, not in some scientific journal, not mixed up with other papers on other subjects, but it is in the journal of a society devoted to telegraphic purposes, the existence of which, I should think, can hardly be unknown to persons skilled in such matters in this country, and where it seems to me very natural that anybody would search for information, as, in fact, Dr. Muirhead did search for it, and to some extent found it. It is true that the only person who is shown to have consulted it in this country is Dr. Muirhead, who, though unable to read German, was enabled by his knowledge of the technical terms to spell out some information from the paper.

Upon the whole, though not without some doubt, I have come to the conclusion that there is evidence before me upon which I infer that the communication made by Legat in that journal must be considered to have been within the knowledge of persons skilled in these matters in this country; it appears to me that that is the fair inference from the facts proved before me. I need not say in coming to that conclusion I have endeavoured to attend to all the earlier decisions, including the decision of the Court of Appeal upon the Patent Skate case; and I think that the conclusion which I have already expressed is consistent with those decisions; though I am bound to admit that different minds might, as a matter of fact, come to different conclusion on the matter. Assuming then that the second Reis, as described by Legat, was a matter of public knowledge, it remains to consider whether the instrument as there described was an anticipation of the receiver as patented by Mr. Bell. In my judgment it was not. Looking at the plates it appears to me to be plain that the armature in Reis's receiver was not a disc at all, it was not a plate at all, but that it was a beam, a solid bar—when I say solid, I do not mean that it was rectangular; it appears to me to have been a bar whose section was oval—and that is the result which is conveyed to my mind by the plate, and I think that the model which has been exhibited before me in which that bar is converted into a twisted or curved disc does not really and truly represent the instrument as described by Reis. I think, therefore, that the criticisms of Sir Frederick Bramwell on that model were perfectly well founded, and that there was nothing in the Reis which can be considered to have been an anticipation of the armature of the description indicated in Bell's patent. No doubt Reis's invention is coming near to the invention which was afterwards made by Mr. Bell, but it appears to me not to be the same; and I am not at all convinced that it will operate in the same way. It is perfectly true there is some evidence before me that Reis's instrument will speak, but it does not appear to me that there is any evidence which shows that it could be made successfully to speak before Mr. Bell's patent was made known; and it is obvious that the advances which have been made in telephonic science, very largely in consequence of his discoveries, have enabled persons to use instruments in a manner which neither their inventors nor their users could have used them before the discovery, and I think this must be further borne in mind, that instruments as little like the true Reis as the ones that have been exhibited would, I have no doubt, apply within the description of Reis's instrument as being universal instruments. I next approach the inquiry whether the disclosure which has been made through Sir William Thomson, and through the various scientific papers which copied or examined this instrument before December, 1876, the Glasgow receiver, made the principle of the Bell receiver which was afterwards patented a portion of the public knowledge. As I have already mentioned, Sir William Thomson explained during his discourse at Glasgow—both the transmitter and the receiver—they were not in action; they do not appear to have been connected, and no experiment was performed or at that time could be performed by Sir William Thomson to explain their action, because, as I have already said, he had attempted to make them speak, and he had failed. Both instruments, as I gather, were on exhibition some time afterwards, at first apparently in the room in which the lecture had been delivered, and at a subsequent date in the laboratory of the Glasgow University, which was open to everybody interested in the subject; and there is evidence before me from which one would infer they were the objects of continual curiosity to persons interested in this class of discovery. Professor Barrett saw them there, and made drawings, which he exhibited to his class at some date or other; and Dr. Muirhead made a rough sketch. The announcement of Sir William Thomson was communicated to Mr. Ayrton, who at that time was thousands of miles off, and a description of it appeared in the *Telegraphic Journal* of October, 1876; every person one may suppose, who is interested in such things, probably within the four corners of the world soon became aware of the discovery which had been announced by Sir William Thomson.

That the Glasgow receiver can now be made to speak, though not very distinctly, I know from what has taken place in this court, because I have heard it; but I do not forget that the utterances which I heard were the result of applying to this receiver a great amount of galvanic energy, and a transmitter, which, so far as I can learn, was of a perfectly exceptional character, a Hunning furnished with seven separate cells; further, I have no evidence that any one made the Glasgow receiver speak before the publication of Bell's invention. There is no doubt that, as exhibited at Glasgow, the armature was fitted on by a screw and with a tilt, and there can also be no doubt that some of the most competent and skilled persons who saw it, like Sir William Thomson himself, came to the conclusion that the disc was intended to be so used, and that the tilt was part of the design and intended structure of the instrument, and that is not wonderful when one bears in mind the fact that down to this time almost all the experiments which had been made, or instruments which had been formed for the purpose of transmitting speech, had used an instrument in the nature of a free reed or tongue, and that this disc so fastened on had, therefore, the position of a free reed or tongue—it might be operated upon by the galvanic attraction of the circles of the receiver. There were others who saw the instrument, and who came to the opposite conclusion; but I have before me evidence which shows that Mr. Dunscombe, an instrument maker, who was instructed to make a copy of it from a photograph or from an engraving published of the Glasgow receiver, made it purposely with the tilt. In this conflict of evidence I have come to the conclusion that it was far from plain that the tilt of the disc was not an intentional part of the structure. The effect of this tilt on the action of the disc is great; it makes it act, as regards its vibrations, partly as a tympanum and partly as a free reed. As the armature appeared at Glasgow it was, in fact, intermediate between the old form of armature, the free reed, and the latter form of Bell in which the flat disc was used. The Glasgow instrument differed in other particulars from the Bell receiver; in the Bell the magnet was wholly within the case, and the circumference of the disc rested on the wood, and was held down by the wood; in the Glasgow receiver the magnet was annular, the circumference of the instrument being one pole and the interior core the other,

Digitized by Google

and the disc when held down at all was held down by the magnetic attraction, a form which requires, as I think, a much greater exertion of galvanic force than the mere adoption of a disc mechanically kept in front of the magnet; lastly, the Bell receiver is capable of being used as a transmitter, a quality which does not belong to the Glasgow receiver. These differences may appear to be small, but small diversities in delicate matters often make the whole difference between success and failure; and in the present case I have the distinct testimony of Sir William Thomson and others that the Bell receiver is superior to the Glasgow receiver, and my own experiments with the Glasgow receiver, even under the most favourable circumstance, lead me to the same conclusion. I do not forget Professor Silvanus Thompson's Bristol receiver—I did not at first hear well through it, but subsequently I heard better, but I think that that has been worked with a less tilt than as it was originally made, or than the Glasgow receiver possessed; and with the whole light cast upon the best mode of user by discoveries subsequent to 1876—that instrument I may observe was only made in the beginning of the present year. With the single exception of this Bristol receiver, and another instrument very similar in form, but having a thinner armature, and a rough and unsuccessful copy of the Glasgow receiver attempted by Dr. Muirhead, I find no case of the Glasgow form of receiver even having been used. The burden being on the defendants to show that the anticipation of the Bell receiver by the Glasgow receiver was by an instrument practically as good as the patented one and of an invention which had passed beyond the stage of mere experiment, I think that they fail in discharging that burden.

There remain two other objections to be considered—the first of those depends upon the first clause made in the specification as amended by the disclaimer. That claim is in these words:—"The combination substantially as set forth and described respectively in the fourth and fifth plans above referred to, but subject always to the disclaiming notes of a permanent magnet, or other body capable of inductive action with a closed circuit, so that the vibration of the one shall occasion electrical undulations in the other or in itself, and this I claim whether the permanent magnet be set in vibration in the neighbourhood of the conducting wire forming the circuit, or whether the conducting wire be set in vibration in the neighbourhood of the permanent, or whether the conducting wire and the permanent magnet both simultaneously be set in vibration in each other's neighbourhood." This claim is said to be a claim to undulatory currents pure and simple; that is, to the combination of a vibrating magnet with a current, all of which was well known to Faraday. To accomplish Mr. Bell's object four points of correspondence or identity are necessary. In the first place, the vibrations of the transmitting magnet must correspond to the vibrations produced by the voice; in the second place, the undulations of the electric current must correspond to the vibrations of the transmitting magnet; in the third place, the vibrations of the receiving magnet must correspond with the undulations of the current; and, in the fourth place, the audible vibrations in the air must correspond with the vibrations of the receiving magnet. If all these correspond, the desired result is produced. Mr. Bell's real stages were the first and the last, the bringing together of the vibrations in the air and of the two magnets at the two ends of the operation, the unification so to speak of the diaphragm and of the magnets—but the first claim, so runs the argument, is to the correspondence of the vibrations of the transmitting magnet with the undulations of the current, a thing as old as Faraday, and hence the patent is void. But the patentee himself has shown his consciousness of what his old knowledge was, because in the passages which I read he explains, as it seems to me, with reasonable clearness, that the correspondence between the vibrations of the magnet and the undulations of the current was a thing well known of old. To read the first claim therefore as one to Faraday's invention would be to make the document inconsistent with itself, and I think that the words "substantially as set forth" in the fourth and fifth plans introduced into this claim must be taken to confine the claim to the application of Faraday's principles to cases where the agitating magnet or inductive substance is itself agitated by the voice. I have already expressed my opinion that Mr. Bell was the author of a very remarkable discovery. I think, furthermore, that he has endeavoured honestly to describe that discovery in his specification, and where these two things are found, I think it is the duty of a judge to give, if needful, benign interpretation to the words of the document.

Lastly, it is objected that by his original specification Mr. Bell claimed to use for his disc or plate either membrane or steel or any inductive substance, and that by his disclaimer and memorandum of amendment he finds steel to be preferable, and claims not any inductive substance, but any equivalent plate capable of inductive action. I am unable to see in this change anything that can affect the validity of the patent. I think the description of the subject matter of the plate is adequate, and that the plate as described must be inductive, and equivalent to a steel plate as regards its capacity to vibrate with the voice. When those qualities are found it seems to come within the description contained in the amended specification. Those being the objections made to Bell's patent they all in my opinion fail, and I think that therefore the plaintiffs are entitled to an injunction to restrain the sale of the two receivers which are alleged to be violations and infringements of that patent.

I now approach the second part of the case which deals with Mr. Edison's patent. If a portion of the circuit consists of substances the parts of which are capable of being brought near to one another by pressure, the effect of the pressure will be that the resistance of the circuit will be diminished and the current will be increased. The most important part of Mr. Edison's invention consists in using the principle to produce undulations representing the voice by means of a plate actuated by the voice and causing pressure on the circuit, and according to the view of the plaintiffs' witnesses and of Professor Dolbear it is requisite for the practical success of this plan that there should be used a material of low conductivity. It is further requisite that it should possess, either in itself or in the mechanism by which it is supported, sufficient resiliency to revert to the condition in which it existed before the pressure was exerted. This device was called by Mr. Edison a tension regulator. The principle involved was not new; the law that the current of a given battery varied inversely with the sum of the resistance of the circuit was old and familiar to electricians; and the fact that resistance was capable in certain cases of being diminished by pressure was known as regards certain materials, though the effect of pressure on the resistance of metals and any other substances was at the date of the patent an obscure subject, and appears to be still far from expostulation. Wherever the metallic point had constituted part of a circuit, and had been subject to any pressure, inasmuch as all metals have some elasticity, there had been, in theory, a tension regulator, because the resistance lessened as the faces of the metal points broadened. Such a tension regulator as Mr. Edison invented has been discovered in Reis's instrument. Again in Clerac's tube, carbon in some form or other had been subjected to pressure in order to lessen the resistance to the current; but there the result was produced by screws, and was not varied automatically in proportion to any other force. In Mr. Bell's patent of 1876 the production of electrical undulations, by alternately increasing and diminishing the resistance of the circuit, had been explained, but the mode for use had the electrodes in water, the mode of action of which was limited, to a certain extent, by reason of the generation of gases from the electrical decomposition of the water. Another similar invention appears to have been made by Mr. Gray, but its precise nature has not been disclosed to me, and nothing has been produced to affect my conclusion that Mr. Edison, by putting a plate, actuated by the human voice, of a substance capable of having its resistance diminished by compression and requiring resiliency, had a novel and brilliant discovery of course associated with it. Mr Edison's patent bears date the 30th of July, 1877; the specification was filed on the 30th of January in the following year, 1878. Two disclaimers and memoranda of alterations have been filed, one of the 10th of February, 1880, and the other on the 13th of June, 1881, and by those memoranda very great alterations have been made in Edison's original claim.

It now becomes necessary to consider the specification of Mr. Edison, and the question which is so closely connected with it, as to whether the Hunning transmitter is an infringement of the specification. On referring to the specification, as amended by the disclaiming notes, it will be found that Mr. Edison uses this language: "This invention relates to that class of electrical instruments in which sound becomes one of the elements in the transmission of the communication, and a corresponding sound is produced at the receiving station, so that oral communications can be sent by electricity, and clearly distinguished at the receiving station. Musical tones may also be sent, but my present invention is especially available in transmitting and receiving oral communications. In transmitting musical tones the respective notes each have a definite period for each vibration, hence there is a response at the receiving end from the notes that vibrate in time with the electric pulsations sent, but in speaking there is little change in the musical tone, but considerable in the modulations and inflections of the voice. In my present invention I make use of the vibrations given to a diaphragm or tympan." I pause there to make this observation, that, in considering this specification, two questions principally require decision—the first is as to the nature of the diaphragm or tympan referred to in the specification; the second is as to the matter of the tension regulator, and what parts necessarily go to make up that tension regulator, as substantially described in the specification. Now, before reading further, I will make this observation: that it appears to me that the words diaphragm or tympan ought to receive their ordinary signification in this specification, unless there is anything to show the contrary. The ordinary signification of the word diaphragm I take to be a mere partition or separation—something which, as one witness said, separates something from something else. It is, perhaps, most often applied to a separation existing in that which but for the separation would be one continuous cavity; but it is not in my judgment necessarily confined to that use. A tympanum, or, as the word is used in the specification, tympan, signifies in my judgment primarily a thing like a drumhead—a thing in which a substance elastic in itself, but not acting as an elastic substance unless strained, is strained over its circumference and acts in the manner of a drumhead. Now it will be observed throughout this specification that what Mr. Edison refers to is a diaphragm or tympan. I say that, not forgetting that in some cases he uses the one word, and in some cases the other, and according to the conclusion which I have arrived at, which I will now state, in order that it will make more plain the meaning of the specification, I think that the quality which he required in his diaphragm is plainly expressed in the specification, namely, that it shall vibrate with the voice. It has been urged upon me that a tympan possesses another quality, that of magnifying the vibrations produced by the voice. It is quite true that a tympan does possess that quality, but it is equally true that a diaphragm by no means necessarily possesses that quality, and it appears to me that using the words interchangeably and describing the quality that they must possess, that of repeating vibrations, it would be wrong to require in everything which is to come within the ambit of this specification a quality not belonging to a diaphragm, and not expressed or referred to in the specification as being essential to its operation. Making those observations, I now return to the reading of the specification. "In my present invention I make use of the vibrations given to a diaphragm or tympan, by speaking into a resonant case, to produce a rise or fall of electrical tension upon the line with such accuracy that the electric pulsations or waves will represent the atmospheric sound waves produced by articulation, and the electro-magnet at the receiving station will respond to the electric waves in such a manner as to reproduce articulation by acting upon a resonant plate." There I find that the diaphragm, or tympan, whichever it is, is to be something which will vibrate, and which by its vibrations will give rise to the rise and fall of the electric current, nothing more. Then referring to the pictures or diagrams he says, "The resonant tube or box *a* is of a size and shape adapted to being spoken into, the same having an opening at one end or side, and a diaphragm or diaphragms *b*, against which the sound waves from the human voice act, and these and the motion that the diaphragm receiver is the means of producing a rise and fall of electric tension on the line by the devices hereafter set forth." Now, there again I find that what he aims at is a diaphragm vibrating with the sound waves, nothing more, which by its pressure on the substance below operates on the electric current. Then he says—"The general features thus described pervade my entire invention." We have therefore arrived at the general statement of his invention. Then he proceeds—"But in developing the same many useful and important modifications and variations have been made, which I will proceed to set forth." Then, after making some remarks, which it is not necessary for me to read, and referring to the difficulty he had experienced in producing hissing consonants, and to the form of the box which is intended to get over that difficulty, he says:—"The next feature requiring consideration

Digitized by Google

is the character of the diaphragm in the speaking instrument. Many materials have been employed by me, such as metals, horn, vellum, celluloid, ivory, &c.; but almost all of these produced a prolonged or secondary vibration from their own resonant character, hence the articulation is defective, and the sound vibrations blend. After extensive experiments, I find that mica is almost entirely free from any resonant action, and hence it will respond with the greatest accuracy to the sound vibrations, and being of a laminated character can be employed of any desired thickness, and when secured at its edges responds with the greatest accuracy to the sound vibrations, and does not require to be strained; furthermore, the changes of temperature and atmospheric condition have little or no effect upon the mica diaphragm or tympan." I only pause to observe here that it is plain that the mica structure is not, properly speaking, a tympanum, because it is not strained, and that he therefore shows that what he prefers above all others is that which is more properly described as a diaphragm and not as a tympanum—of course, I do not forget it has a certain operation as a tympanum; but what I mean is that the mica not being strained is not within any conception of a tympanum, as usually described. Then he says, "I find it is not practical to open and close the line circuit in instruments for transmitting the human voice, the circuit to the line must be always closed, and the transmission be produced by a rise and fall of electric tension, resulting from more or less resistance in the line. This resistance may be produced in several ways." Now we approach his description of the tension regulator. "I have shown several which will hereafter be named, but I find the most delicate to be small bunches or tufts, or discs of semi-conducting elastic fibre such as particles of silk, and an intermediate conducting or semi-conducting material. This device I call an electric tension regulator; it is more or less compressed according to the vibrations of the diaphragm or tympan, and the electric current rises in tension as it is compressed or lessens as the fibre expands." Then he proceeds to describe more in detail the application of this particular electric tension regulator, and he says:—"The fibre is rendered semi-conductive by being rubbed with plumbago, soft metal, or similar material, or by a deposit of metal upon its surface, or by fine particles of conducting or semi-conducting material mixed with it, that conducting power varying with the density of tuft or bunch of fibre." That tension regulator, consisting of the silk with the metallic coating or other substance put over it, is the one which is described in greatest detail by Mr. Edison; but many other forms of tension are described, and those, it appears to me, may be classified in this way. I find a tension regulator constituted of semi-conductive substance with inherent resiliency, such as the one I have already described. I find others which are to be constituted of a semi-conductive substance with an artificial resiliency, that is, a resiliency gained by a spring or other mechanism by which it is applied. I find others in which the operation proceeds on a different principle, they depend on circuiting, as it is called; that is to say, on diminishing the distance through which the electric current has to travel. And those, again, are of two kinds; there is one the operation of which is a little complicated, operating by a spring, and there is another in which the electrodes are inserted in water—the electrodes by pressure from above approaching other electrodes below, therefore diminishing the water space between the two—and, lastly, there is a very complicated arrangement with a rheostat, the short effect of which I conceive to be that a current which in its nature but for the rheostat would have been intermittent is converted into a continuous current, the rheostat operating for a sufficient time to prevent the current ever entirely ceasing, and in that way a continuous but undulatory current is produced.

The claim made in respect of these tension regulators is this:—"In an instrument for transmitting electric impulses by sound, a diaphragm or tympan of mica, substantially as set forth." I have already expressed my opinion that the words diaphragm or tympan must be taken to be used in their natural sense—anything which separates the substance below from the air or the substance above would be a diaphragm, anything which is stretched in the nature of a drumhead would be a tympan, and both those according to the description must be capable of being vibrated by the voice, and if they are that, they are diaphragms or tympans within the meaning of the words as used in the specification.

There remains to consider what is the meaning of "the tension regulator substantially as hereinbefore described." It appears to me plain that the patentee did not intend, and the specification does not intend, to confine them to the particular forms of tension regulator which have been indicated. The description of the first form, as I have already observed, is the most minute; I find as requisite, first, the quality that with its compression the resistance shall be lessened and the current shall be increased. There is probably a quality present, more or less, in all cases in which the substance through which the current passes is broken into pieces. The resistance lessens as the interspaces increase, and *vice versâ*. Secondly, I find that its substance must either from its inherent character, or from its composition as a whole, be of a semi-conductive character; the material must not be an absolute non-conductor, for that would destroy the current; it should not be a good conductor, for then the interruption would probably bear so small a proportion to the current as not adequately to influence the stream, or create sufficient undulations in the result. Accordingly the evidence satisfies me that, though theoretically high conductors could be used as tension regulators, and though such substances had been occasionally used with success, yet practically, and especially with a view to the uniformity of results, semi-conductors are best. It is said that this result is due to the fact that in high conductors the point of fusion is low, so that the pieces get fused together; but as it appears that all the high conductors are easily fusible, and the semi-conductors are not so, the distinction drawn was sufficient for practical purposes. Thirdly, I find the material must have had such a resiliency as will enable it on the withdrawal of the pressure to return to its previous condition, and thus affect the current which had been increased by the pressure, and be ready again to yield to pressure and again to recover its old position. The necessity of such a quality I find expressed not only in the description of the silk, in the first part, as an elastic fibre, and in the various contrivances to produce an artificial resiliency, but in the general description of the nature of the instrument which requires such a recuperative elasticity if it is to act on more than one single occasion. Accordingly I find that in the various forms of tension regulator indicated in the letters patent this resiliency is acquired, though in various ways; in some by the inherent elasticity of the substance, the silk or cork; in some by the elasticity, as in the cases where plumbago points are used by means of springs; in some as in the lamp-black, and in the coke by the pressure of the elastic gases in the interstices of the material. I think, therefore, that the true meaning of the claim which I have just read is the union of a tympan or diaphragm capable of vibrating under the sound waves with an electric tension regulator having the quality which I have just described, because that appears to me to be an electric tension regulator substantially hereinbefore described.

I now approach the question which is very intimately connected with the consideration of the specification—Is Hunning's transmitter an infringement of Edison's transmitter? In Edison's transmitter we find, first, a diaphragm or tympan, or plate, which receives the sound of the voice. Below that there is a cork, not of the same size as the diaphragm, placed in the centre, and of a smaller area. Below that comes a piece of platina foil, which is the same size as the cork, and corresponds with the size of the cavity in which the tension regulating substance is placed, in which is one of the electrodes in the current. Below that comes the lamp-black or other substance which is used for the purpose of the tension regulator, and below that comes the bottom of the box, which is itself the electrode, in which is placed a screw for the purpose of initial regulation. The Hunning transmitter is different in this way—that it has no diaphragm or cork separate from or other than the platinum foil. The platinum foil in Hunning's receives directly the human voice. They are of the same character, in there being a cavity or cell in which the metal bottom is one electrode, and the platinum foil at the top the other, but the differences are, I believe, to be fairly stated as follows:—First, the materials in the cell are different; coke has been used by Hunning, lamp-black has been preferentially used by Edison. Coke is not mentioned with any of the articles used in Edison's specification. In the next place the size of the particles is different, the particles of lamp-black being, in fact, very much smaller than the particles into which the coke is crushed. In the next place, as I have already pointed out, there is in Edison's the superimposition over the platinum of cork and disc; and, lastly, there is the screw at the bottom which is applied in the Edison for the purpose of giving initial pressure, and there is a certain amount of difference in their action. In Hunning's the up-and-down motion produced by the voice is communicated through the foil to the particles directly; in Edison's, the up-and-down motion of the voice is translated into circular nodel ripples in the disc or tympan; this is re-translated, so to speak, to the centre, into an up-and-down motion which is communicated to the cork, and which the cork communicates to the foil, and the foil to the air. The result appears to me to be that that action in Hunning's is more accurate because more direct; in Hunning's case there is not that magnifying of the operation of the voice that takes place in the presence of the tympan or disc in Edison's. The Hunning transmitter appears to me, therefore, to be an improvement on Edison's patent, but it may none the less be an infringement of it, and I have come to the conclusion that, like Edison's, it is the combination of a diaphragm, vibrating with the voice, that being the platinum foil, with a tension regulator consisting of a semi-conductive resilient and compressible substance, and it is therefore within the scope of Edison's specification.

It has been argued that Hunning's transmitter acts on a different principle to Edison's, that the one demands compression and the other freedom of motion; that in the one the presence of a diaphragm is essential, and that in the other it is not—but the evidence, amongst others, of Professor Dolbear, shows that the presence of the foil is essential or useful in both cases. In both cases it acts as an electrode, in both it requires extension in order that an electric current may pass through all parts of the substance which constitute the tension regulator; in both it keeps the enclosed substances in their places. Before passing from this subject, and, considering the meaning of the word diaphragm, I think it not immaterial to observe that Mr. Hunning, acting with the assistance of the patent agent, whose name he mentioned to us, in describing his own invention, described the top of the platinum foil as a vibrating diaphragm. That is exactly the conclusion which I have drawn—that the platinum foil is a vibrating diaphragm, and I have concluded that Edison described as the essential requisite of his invention the combination of a vibrating diaphragm with a tension regulator.

The discovery Professor Hughes made in 1878, that the vibrations produced by the voice might operate on a heap of particles directly and without the intervention of any diaphragm or tympan, or any such thing, has in my opinion suggested the argument that Hunning's and Edison's transmitters operate on different principles; but not only is it the fact that the Hunning transmitter is not used without the platinum foil, but it has not been shown that it can be so used with success, and, according to the evidence of Professor Silvanus Thompson, the same physical principle, namely, that of diminishing the resistance and increasing the current by the increase of contact from pressure, underlies the light of the tension regulator of Edison and the microphone of Hughes.

I now come to consider the two objections which have been made to the validity of Edison's patent on the ground of the nature of the claims. The first of those is based upon the first claim, which is in these words "in an instrument for transmitting electric impulses by sound." If it did, it appears to me that the claim would be bad, because I think it is really the claim of the application of an old substance to a particular purpose without the use of any ingenuity in that application, without the use of any invention in that application; but if it means that the mica diaphragm is claimed in an instrument for transmitting electric impulses by sound, which is described in the specification, then I think that it is not in any way bad, and upon the whole I have come to the conclusion that it may be read as relating only to the mica diaphragm in combination with the rest of the instrument. It is to be borne in mind that in construing claims one must construe them not as enlarging the operation of the description, but rather as disclaiming everything which is not claimed. They are inserted for the purpose of drawing the line between what the patentee knows to be old and what he desires to claim as new in the invention he has described.

I now come, however, to the last and very serious objection to the validity of the patent. It is this—Mr. Edison discovered an instrument of the highest ingenuity, which is commonly called the phonograph. That instrument is a purely mechanical one, it has nothing whatever to do with electrical or magnetic science, it has nothing necessarily to do with the

Digitized by Google

transmission of sound to a distance, it is in substance a diaphragm actuated by the voice, which operates upon a style, which impresses itself on an impressible plate. The impression which is made on that plate again actuates a style, which again actuates a diaphragm, which again actuates the air—that which is operating the one diaphragm in the form of human voices is reproduced on the other diaphragm in the condition of audible sounds. Mr. Edison points out in his specification that the voice can thus be produced by the second diaphragm. He also points out that the instrument may be used in another mode, namely, by connecting the second diaphragm with a transmitter, and using that diaphragm as the diaphragm of the transmitting instrument, in which case the second diaphragm not immediately produces an audible sound, but produces an undulation of the electric current, while at the end of the current the receiver reproduces the audible sound. The description which is given of the instrument is this:—"I am enabled to record the sounds produced by the human voice or otherwise by causing the movements of the diaphragm to be registered on paper or soft sheet metal, and then the paper may be used in an instrument to reproduce the sound upon a delicate diaphragm by giving to the same a vibration similar to that originally given by the voice." Then he proceeds to describe the figures:—"Fig. 4 is the indenting transmitter, the diaphragm having a knife-edge point; *i* is the paper which has previously been passed through a machine to raise a V-shaped rib, 6. The movement of the diaphragm of *h*, when the drum is in motion, causes the knife-edge point *l*[1] to indent the raised rib to varying depths, according to the amplitude of vibration of the diaphragm. Thus these indentations represent accurately all the tones and varying inflections of the human voice. The paper, after being indented, is passed through a second apparatus in Fig. 5, almost similar to *h*. A spring, 9, has a knife-edge, which rests upon the raised indented rib 6, the spring being connected to a delicate diaphragm, 10, by a string or straw. The indented rib reproduces in the spring 9 the movement of the indenting point, and either by direct action, or through the vibration of a string, conveys the same motion to the diaphragm of *n*, and reproduces previous sounds."

Now pausing here, it appears to me to be plain that Mr. Edison has described a substantive discovery of the very highest interest and ingenuity, by which at one spot this instrument receives and reproduces the human voice. Then he goes on to say, "If these sounds are to be transmitted over a telegraph line the diaphragm 10 is provided with a cork disc and fibrous tension regulator," and then, as I have already pointed out, the second diaphragm, instead of reproducing the voice at the time, acts in fact upon the tension regulator. Now what is the claim made by Mr. Edison in respect of that apparatus? It is this—"The method herein specified of recording the undulations of the diaphragm of yielding material, and the reproduction of sound by such material acting upon a diaphragm to communicate to the same vibrations similar to the original ones, substantially as set forth." It is impossible for me to read that claim and not to believe it to be a claim to the instrument whether used in combination with an electric current or not. Its capacity to produce sound without any relation to the electric current has been pointed out and dwelt upon. The mode of indenting was a novelty; the mode of reproducing that sound was a novelty; and the claim appears to me to cover the phonograph in both its applications, its application to produce human sound directly and immediately at the spot when the voice had been spoken to it, and its application also as a transmitter of the same voice at a distance. Has that remarkable discovery so made by Edison been in any manner described in the provisional specification? The statute, as we all know, requires that the provisional specification shall describe the nature of the invention, and before I proceed to consider the provisional specification in this case, I think it desirable to refer to some of the authorities which explain the principle upon which I ought to proceed in considering it. In the case of Bailey *v.* Robertson, which has been referred to so often during the course of the argument, Lord Blackburn very clearly explains the function of the provisional specification. At page 1874 his lordship says:—"The patent law dating from the time of James gave a monopoly solely to that invention of the first inventor; it, therefore, gave a monopoly solely to that invention which was his invention; he could not claim an invention greater than the title of the patent, but the titles were of extreme generality. It is in this particular instance 'for improvements in preserving animal substances.' Almost any kind of thing would come under that description; the mere title gave very little instruction. Then, in the time of Queen Anne, the Attoney-General of the day invented what was obviously a very great improvement. He made it a condition that the patentee should, within six months, particularly 'describe and ascertain' the invention and the manner in which it was to be performed, if not it should be void. If that was done at the end of six months, that specification fixed what was the invention for which the patent was granted. Then, during the six months, it would have been, and before specifications were invented it must have been, a question of evidence of what was the invention for which he went to the Crown, and for which the Crown granted a monopoly, and the traverse of that would be the proof. Then came the statute of 1852, which introduces a further amendment. It enacted that when persons went to apply for letters patent they should deposit a provisional specification. That provisional specification describes the invention in terms very different indeed from those in which the final specification described it. In this case, instead of saying, It shall particularly describe and ascertain the nature of the invention, and in what manner the same 'shall be performed,' all that the applicant leaves with the law officer of the Crown when he applies for a patent, he shall state the nature of the invention—no more than that; and then, when the law officer of the Crown, to whom it is referred, has looked at it and finds it does state the nature of the invention, but thinks the nature of the invention as stated is too large or too vague, he may require him to amend it; but if not, then he grants a certificate to use the patent publically without at all thereby making a present of the discovery to the public; and when it came to be a question whether or no what he was doing during that six months did avoid the patent, I take it the process must have been to say, look at the nature of the invention described in the provisional specification, and say whether this which you have been doing, and which you say was a part of the patent, is fairly within the nature of the invention you have described. In that case you are protected, but if it is a new and separate invention, and a different one, then you are not protected. I cannot but think that when that is once looked at it becomes pretty clear that, when the nature of the invention has been described in the provisional specification in the way which has been mentioned, if something were found out during the six months to make the invention work better, or with respect to the mode in which the operation may be performed, a thing which is very likely to happen when, in carrying out his invention, the inventor finds that some particular bit will not work so smoothly as he expected, and it is necessary to add a little supplement to it, still the nature of his invention remains the same, and it is no objection that in the complete specification, which comes afterwards, the invention or application is described more particularly and in more detail, or even if it be shown that there has been more discovery made, and so as to make the invention which he has described in the provisional specification really workable. If nothing more is done than that, I think it is good; but as soon as it comes to be more than that, and the patentee says, in the provisional specification I describe my invention A, and in the complete specification he says I hereby describe A, and also B, then as far as regards B, it is void, because the letters patent were granted for the invention that was described in the provisional specification, and do not cover the invention that is described in the other." Again in the case of Newall *v.* Elliott, the Court of Common Pleas made observations to a similar effect. "The office of the provisional specification is only to describe generally and fairly the nature of the invention, and not to enter into all the minute details as to the manner in which the invention is to be carried out." And similar language is used by the Master of the Rolls in one of the cases which have been referred to, where he says it might be roughly, but it must be fairly done.

Now I turn, with the light thrown by those cases as to the proper mode of construction, to the provisional specification in this case, and find that the title, which is to be read as part of the provisional specification, is, "Controlling by sound the transmission of electric currents, and the reproduction of corresponding sounds at a distance." And the inventor proceeds in this manner, he says—"The vibrations of the atmosphere, which result from the human voice, or from any musical instrument or otherwise, are made to act in increasing or lessening the electric force upon a line by opening or closing the circuit, or increasing or lessening the intimacy of contact between connecting surfaces placed in the circuit at the receiving station; the electric action in one or more electro-magnets causes a vibration in a tympan, or other instrument similar to a drum, and produces a sound, but this sound is greatly augmented by mechanical action. I have discovered that the friction of a point or surface that is in contact with a properly prepared and slowly moving surface is very much increased or lessened by the strength of the electric wave passing at such point of contact, and from this variation in the friction a greater or less vibration is given to the mechanism or means that produce or develop the sound at the receiving station, thereby rendering clear and distinct the sound received that otherwise would not be audible." I pause there to observe that it is plain that that description refers entirely to the transmission of sound or the controlling of sound by means of electric currents, or electricity in some form or other, and cannot in my judgment be taken to apply to an instrument which is capable of being worked in a very remarkable manner, without the application of electricity in any shape or form. Then the inventor proceeds in these words—"to carry out the peculiarities of my invention." It is obvious, therefore, that the substance of the invention has been disclosed in the preceding paragraph, "to carry out the peculiarities of my invention under the varying conditions of use I have devised several modifications of the transmitting, receiving, and intensifying devices employed in this sound telegraph," all evidently referring to sound to be transmitted to a distance, "portions of the apparatus are interchangeably available in transmitting or recording," and I observe, in passing, the evidence goes to show that at that time recording, as used in connection with telegraphy, meant some sort of telegraphic representation of the sound, because no other had been known till this invention was made—"others are adapted to local use," some are only available in "transmitting, and others are only for receiving, and some portions of my improvement can be availed of to make a record of the atmospheric sound waves or of the electric waves or pulsations corresponding thereto, or resulting therefrom." Now, no doubt, some of those words do explain, or might be held to refer to an instrument like the phonograph; but when I ask myself whether they in any manner describe the nature of the invention, I am bound to say that they do not. These, as I have already observed, are merely methods for carrying out the peculiarities of the invention; which invention, I repeat, is confined to the transmission of sounds by electrical agency to a distance. Supposing an inventor had, during the six months which preceded the complete specification, invented the phonograph, not as applied to the electric telegraph, but by operating itself, can it be said that the invention would have been protected by the description contained in this provisional specification of that instrument. I agree that the provisional specification need not describe the manner in which an invention is to be carried into effect. I agree that it need not describe the nature of the invention otherwise than roughly; but it ought to do so fairly and honestly, and if Mr. Edison was at the time at which these letters patent were granted in possession of that very remarkable mechanical invention by which speech could be reproduced, not necessarily at a distance, but in the same room as that in which it was uttered, I do not think the provisional specification was an honest statement of the nature of that discovery.

On that ground I come to the conclusion that Mr. Edison's patent cannot be upheld; and I must, therefore, grant an injunction in respect of the first part, and dismiss the action as regards the second.

Then arises the question of costs, and, upon the best consideration which I can give, I think I shall act in mercy to the parties if, instead of apportioning the costs, I grant the injunction without costs, and I do so accordingly. The form of the injunction will be the usual one. I think it will be found at page 352 of Sir Henry Seton's book: "The injunction be awarded to restrain the defendant, his agents, tenants, &c., during the continuance of the letters patent"—of course you refer to the particular ones—"or any extension thereof from manufacturing or selling, or disposing, or using any instrument of the same construction"—as to the two exhibits which you will introduce, "or only colourably differing therefrom, or any other instrument constructed according to the plaintiffs' patented invention, or only colourably differing therefrom, or being an enlargement of the plaintiffs' said patent, and from in any way infringing the plaintiffs' said patent."

THE ELECTRICIAN.

TO CORRESPONDENTS.

All communications to be addressed to 396, Strand, London, W.C.

All letters intended for insertion in THE ELECTRICIAN, *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

We cannot undertake to return drawings or manuscripts, and must, therefore, request Correspondents to keep copies.

SUBSCRIPTIONS.

THE ELECTRICIAN *can be had, by order, from any newsagent in town or country, at the various railway stations; or it can, if preferred, be supplied direct from the office, on the following terms (paid in advance):—*

Quarterly .... 4s. 10d.
Half-yearly .... 9s. 9d.
Yearly .... 19s. 6d.

P.O. Orders to be made payable to James Gray, at West Strand Post Office.

THE RECENT TELEPHONE DECISION.

In venturing to review some of the scientific details of the careful and elaborate judgment delivered on Friday last in the High Court of Chancery by Mr. Justice Fry in the late telephone suit two preliminary remarks will not be out of place. Firstly, remembering the adage, "*ne sutor*," these remarks will be confined strictly to scientific and technical matters, avoiding entirely questions of law and interpretation. Secondly, the care, patience, and extraordinary clearness with which the various points raised in evidence were treated from the Bench must have struck all persons in court. No trial could possibly have been more fair, and it is only to matters of scientific fact and their logical significance, some of which, amid the complicated issues raised, seem to have been overlooked, that the following criticisms, if such they can be called, are directed.

In the judgment, as printed from the shorthand notes, it is stated that the telephones which existed before 1876, "in certain cases were found, occasionally and uncertainly, to reproduce vocal sounds *with* musical ones, especially vowel sounds;" also that "an inventor, the German Reis, had gone a step further, and used a membrane to set a piece of metal in motion." Now, whatever Reis may or may not have accomplished, he was led by the study of the human ear to construct an instrument which he called a "Telephon," in which, for the first time, there was a combination of a *tympan* with a device for regulating, by means of a *loose-contact*, the flow of an electric current. This device, in which two pieces of conducting metal—preferably platinum —were brought into more or less intimate contact by the motions of the voice acting through the tympan, was, to borrow Edison's term, a "tension-regulator." The term—not a well-chosen one—signifies a device for producing variations in the strength of the current by varying the resistance under different degrees of contact. That it may, with strict propriety, be applied to Reis's platinum contact device is clear, because, as Sir W. Thomson has said, "the resistance between two perfect conductors in contact with one another may be continuously varied from a very large resistance to a resistance of a small fraction of an ohm." It is, therefore, true, as Mr. Justice Fry remarked (p. 11 of "Judgment"), that such a tension regulator as Mr. Edison invented had "been discovered in Reis's instrument." Now, this transmitter of Reis's invention transmitted not only song when it was sung to, but speech when it was spoken to, though in the latter case imperfectly, because, by reason of the delicacy of its construction, any very loud sound broke the continuity of the circuit—a result more disastrous to speech than to song, since to transmit the latter needs only that the number of the vibrations and not their amplitudes or forms be reproduced. The instrument became, in consequence, better known for song than for speech, though primarily intended for both. In his original memoirs Reis recounts how words were transmitted with curious fidelity as to the inflexion or modulation of the voice, though unfamiliar words were not readily recognised. Reis also mentions the importance of keeping the metal surfaces clean. That the instrument not only did speak, but was intended to speak (as a separate function from singing) is attested by a printed document now lying beside the writer, and in his possession since July, 1876. This document is a copy printed in 1865 of the instructions sent out with the instruments of Reis, and in it the person listening at the receiver is directed to signal to the operator at the transmitting end by means of a little Morse key (attached to the end of the receiver to serve as a "call") as follows:—"One tap, *sing;* two taps, *talk.*" It is, therefore, inadequate to the facts to speak of Reis's instrument as having "happened to communicate speech," when such communication was expressly intended and designed. Equally inadequate to the facts is it to say that such speech happened to be communicated "by intermittent currents;" for the transmission of speech with recognisable inflexions and modulations cannot be effected by intermitting the current with abrupt make-and-break. There is hardly a single telephone transmitter in practical use to-day that is not liable to break contact abruptly if subjected to too loud a sound, but when this occurs articulation is spoiled. To this accident Reis's telephone was even more liable on account of the lightness and delicacy of its contacts.

Another statement of the judgment that needs scientific revision is the following, with reference to telephones anterior to September, 1876:—"The fact that down to this time almost all the experiments which had been made or instruments which had been formed for the purpose of transmitting speech had used an instrument in the nature of a free reed or tongue. . ." What are the facts? To transmit speech Reis used a tympan, not a tongue. A tympan, not a tongue, was used in the old toy string-telephone. Tongues were only begun to be used when the musical tone-telegraphs were devised, in 1873 or 1874, in America for transmitting several messages at a time in the Morse code in different musical notes. Such telegraphs were devised both by Graham Bell and Elisha Gray. Each of these inventors, months before September, 1876, had passed from the problem of transmitting tones to that of transmitting speech, and each had already returned from tongues to tympans

Digitized by Google

so soon as the problem of transmitting speech was to be attacked.

Again, it is stated that the "Bell receiver is capable of being used as a transmitter, a quality which does not belong to the Glasgow receiver." Without stopping to inquire what argument is based on this alleged difference in quality the writer will simply state that it is wholly illusory. He knows from his own experiments that the Glasgow receiver *will* act as a transmitter, and that it will, moreover, transmit better than the companion instrument which was shown at Glasgow as the "transmitter;" both of them will "receive," though the membrane telephone (the "transmitter") receives very badly.

The next point calling for remark is the following, which refers to Edison's transmitter. "It is plain that the mica structure is not, properly speaking, a tympan, because it is not strained. . . . . I do not forget that it has a certain action as a tympanum." Now, Edison's specification (page 2) runs:—"The tympans are of parchment, foil, mica, sheet-metal, or similar material." The printed evidence does not show that any witness on either side described the mica structure as vibrating in any other mode or manner than in that of a true tympan Every one of the diaphragms shown—and there are thirty-two of them visible—in the drawings of Edison's specification are true tympans. Further comment is surely needless, or would be if the suggestion that the mica structure is not a tympan were not so innocently at variance with the precise function served by that very definite organ in the combination claimed by Edison. In Edison's provisional specification the word "diaphragm" occurs but twice, and each time as an obvious synonym of "tympan." If in the complete specification it is not used in the same sense, then it includes not only more than is shown in the drawings but more than is included in the provisional specification.

The next and last remark will be by way of comment, not on Mr. Justice Fry's judgment, but on the theory of the telephone as apparently laid down by the claim to employ semi-conducting material in a "tension-regulator." It is well known as a universal law of electricity that any conductor, bad or good, conducts better when in perfect contact than when the contact is imperfect. Therefore, in this universal law there is, theoretically, a means of making a "tension-regulator" out of any material whatsoever that will conduct electricity, by applying Reis's principle of *loose-contact*. Moreover, it is readily proved that, *cæteris paribus*, the better the conductor the better its action in this respect. It is obvious that to throw the current into the most effective undulations in its strength, the changes of resistance introduced by the action of the loose-contact ought to be as large as possible in comparison with the total resistance of the circuit. Now, to produce these changes most effectively, which substance will answer best? It is clear that the resistance should be a maximum when the contact is least perfect, and a minimum when the contact is most perfect. The maximum resistance can be got either with good conductors or with bad conductors, since the resistance of *any* loose joint becomes infinite when all pressure at the point of contact is removed. The minimum resistance cannot, however, be obtained with a poor conductor, for with this, however great the pressure, the resistance will be greater than with a good conductor. It is certain, then, that with good conductors—*cæteris paribus* always understood—the effective changes of resistance will be greater. But, unfortunately, *cætera* are not always *paria*. The best conductors, silver and copper, for quite other reasons, deteriorate rapidly when used as tension-regulators; though they act excellently for a time. The metal surfaces oxidise, and are apt to stick by fusion. Long ago telegraphists knew this, and used platinum by preference as being less fusible and less rustable. Long ago, too, for the delicate contacts of relays it was suggested to use plumbago, which neither fuses nor rusts. Plumbago was *not* used in relays because it happens to be a semi-conductor. Now, taking conductors in order, the best first, and rejecting all that will rust or fuse, the first that remains is *coke*. Coke should, therefore, *à priori* form an excellent material for contact points to regulate the current; and, in fact, for telephonic purposes it is, in one form or other, almost exclusively used. Pure lampblack, which conducts thousands of times worse, and is relatively not even hemi-demi-semi-conductive, will not fuse or rust; but it required all Edison's skill and ingenuity to make of this unpromising material the lampblack button transmitter now practically discarded in favour of the Blake and other transmitters. There is, moreover, no connection whatever between conductivity and fusibility. Sodium, lead, tin, and bismuth are far worse conductors than silver, and far more fusible. Galena and a host of "semi-conducting" substances of kindred character are fusible, as is also selenium. Of the most absolute non-conductors known, some are quite infusible, others readily fusible. Edison has nowhere suggested infusibility as a principle to be applied in his transmitters, and of the substances he names as material for his semi-conductive tension-regulators several—for example, amorphous, phosphorus, and "soft metal"—are far more fusible than the best conducting of the metals is. The opinion that "all the high conductors are easily fusible, and all the semi-conductors are not so" is, unfortunately, against the scientific facts.

THE CRYSTAL PALACE EXHIBITION.

The Direct United States Cable Company.

In the gallery under the large clock the exhibit of the Direct United States Cable Company will be found. We have previously referred to the cables radiating to the East, but the system of this company is towards the West. The company was originally formed in 1873, but the cables were not completely laid until some two years after. The system was open to the public for traffic on the 15th September, 1875.

The cable extends from Ballinskelligs Bay, County Kerry, Ireland, to Ryebeach, Northamptonshire, United States, and has a total length of about 3,000 nautical miles. It is laid in two sections, the main section being about 2,450 miles from Ireland to Torbay, Nova Scotia, and the short section about 550 miles from Torbay to Rye Beach, New Hampshire, U.S.A.

The company started business with a tariff of 1s. per word, but this only lasted a fortnight, and the earnings under this rate were unsatisfactory. The cables were interrupted on several occasions, and in November, 1875, the tariff was raised to 3s. per word, but again reduced in March, 1877, during competition with the Anglo-American Company, to 1s. per word. During the whole of this period the financial results were anything but encouraging, and no dividend whatever was paid to the shareholders, nor was anything placed to reserve. This led to a reconstruction of the company; Mr. Pender, M.P., became chairman, with Mr. J. W. Fuller secretary and manager, and a joint-purse arrangement was made with the Anglo Company, the 3s. tariff being resumed. This tariff has since been varied, in consequence of further competition.

Joint-purse arrangements have also been entered into with the French Cable Company, and with the recently formed

Digitized by Google

American Telegraph and Cable Company, and the tariff now established is 2s. per word, a tariff which we have reason to believe is considered moderate by the telegraphing public on both sides of the Atlantic.

The shareholders have every reason to be satisfied with the management of the Company, seeing that since its reconstruction in 1877 a dividend at the rate of 5 per cent. has been regularly paid, and a substantial reserve fund accumulated. In its recent joint-purse arrangement the Company has secured a strong alliance with the Western Union Telegraph Company of America, which owns and controls the whole of the telegraph service throughout the United States of America and Canada, and we hope that it marks the commencement of a long era of prosperity for the Direct Company and its allies.

The instruments exhibited at the Crystal Palace form a very interesting collection, and show the manner in which the company's entire system is worked between London, Liverpool, and New York. On the land lines on this side of the Atlantic the ordinary Morse printer is employed, while on the land lines on the American side the ordinary American sounder is in operation. Over the main section of the cable the mirror apparatus of Sir W. Thomson is used, and over the short cable there is through working between Torbay and New York, with Allan and Brown's relay and the aid of manual translating apparatus at Ryebeach.

Both cables are worked with Muirhead's duplex apparatus, which has been the means of increasing their carrying capacity to a very considerable extent, giving, in fact, additional transmitting power throughout, equal to a second cable. From the above it will be interesting to note that there is actually only one transmission between the shores of Ireland and New York city, through direct working between Torbay and New York having been established since the introduction of the Allan and Brown relay. The result of this has been a considerable acceleration in the time of transmission, which has been greatly appreciated by the public. As illustrations of the speed of the Direct Company's system, we may mention that ever since the company has been open for business the results of the "Oxford and Cambridge Boat Race," the "Derby," and other important sporting events in which the Americans take the liveliest interest, have reached New York within 30 or 40 seconds after being handed in at the company's London office.

CORRESPONDENCE.

THE SELLON-VOLCKMAR ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Certain statements have lately appeared relating to the above-named accumulators or storage batteries, the patents of which belong to the "Electrical Power Storage Company." With regard to these statements, it is scarcely necessary to give any explanation to those who know me; but, as many who may be, nevertheless, interested in the subject do not, I shall feel obliged if you will publish the following particulars:—Having for long given attention to secondary batteries, and having succeeded in obtaining results which I considered of great value, I took out in England in *September* last certain patents, supplemented later by others. These patents would at the same time have been applied for throughout the world but for the necessity of awaiting the completion of my final specifications.

Towards the end of *December* Mr. Volckmar, whose name I then heard for the first time, was introduced to me as possessing a secondary battery of much merit, which upon examination proved to be in essential points the same as my invention. The patents had been taken out by him in October in many Continental countries, as also in England, and thus the position was, that although later than myself in his application for England, the Colonies, and America, he had anticipated me for the Continent generally. An arrangement was, therefore, made for the amalgamation of our respective interests.

At this juncture a patent was published, taken out by Mr. Swan, of Newcastle, in May, 1881, covering a portion of my first specification, and to prevent any possible difficulties arising in the future I purchased his rights for a considerable sum, and thus the combination of these patents was completed.

I need not here detail the features of the Sellon-Volckmar accumulator further than to say that in the judgment of some of the best scientific authorities of Europe it is an absolutely new and very valuable form of secondary battery, and in no way an infringement upon the Faure, which I assert it greatly exceeds in power and durability.

It was the intention of Mr. Volckmar and myself to deal personally with our patents, but a few intimate friends, who knew of the results obtained, expressed the wish to join with us in their development, and a small private company was formed *the internal arrangements of which are no concern of the public any more than those of a private firm*, inasmuch as no member of the public was ever asked to subscribe, or did subscribe, one single farthing.

The terms which were arranged for the cession of the patents to the Electrical Power Storage Company only concern those (all of high position and thorough business qualities) who approved of and entered into them.

The exact facts are, however, that *the cash paid covered only the expenditure already incurred*, the whole benefits of which were transferred to the company; and that we, the owners of the patents, who had the full right to ask what terms we thought fit, made our whole interest and profit in the business dependent upon its success; and that for a total amount of fully paid-up shares, which might, with the probable extension of capital, yield us each a proportion of the profits equal only to three-sixteenths, we ceded our patents *for the whole world*.

With regard to not guaranteeing the validity of the patents, no counsel of standing ever allows his clients to "guarantee" their patents, however sure they may be of their validity, and the usual clause, which I have always accepted myself in *purchasing* patents, was inserted in regular course. The case was, however, altered when applications were made for concessions or purchase of patent rights *after an attack, which we cordially invited*, had been threatened by the Faure Company, and it was determined to protect any subscribers to subsidiary companies against the contingency of an adverse issue by guaranteeing the return of all money received.

The Electric Carbon Company of Scotland has nothing to do with the Electrical Power Storage Company. Until I saw the prospectus in the newspapers I did not even know of its formation.

With reference to Mr. Volckmar, who I have found to be a gentleman of honour and integrity, the matter has come before the law courts, Mr. Volckmar having immediately upon the original publication of the libel commenced an action; and any discussion thereupon at present would be out of place.—Yours, &c.,

May 20th, 1882. John S. Sellon.

FAURE'S BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The following information may be of some interest to you:—"I reached New York yesterday (May 12th) in the French mail steamer 'Labrador,' that left Havre on Sunday, April 30th, having on board a shipment of seven tons of Faure accumulators, manufactured in Paris by the Force et Lumière Company. These accumulators were fully charged before leaving Paris, and were shipped on board the steamer at Havre in this state. Owing to want of space I was only able to make use of fifty cells during the voyage. With a portion of that number I succeeded in lighting up the smoking saloon of the steamer during the entire voyage with two Edison half lamps, the average time of lighting on each night being about five hours and a quarter. With the remaining cells I lighted part of the engine room and my own cabin, and made experiments with different types of incandescent lamps to test their suitability for steamship lighting. The cells I employed on board have not been touched, charged, or changed during the entire voyage, and I am perfectly certain that they still retain more than half of the charge with which they left Paris. They appear to have stood the voyage exceedingly well, although they were subjected several times to a drenching from salt water, and there seems to have been hardly any visible leakage. I am shortly going to commence the manufacture of these cells in New York, and prior to their completion I shall continue to make experiments with those I have brought with me from Europe." My name is doubtless familiar to you in connection with the Pullman limited express train on the Brighton railway, in which I made the first installation of lighting by accumulators on an English railway.—Yours, &c., W. Lachlan.

Coleman House, New York,
May 13th, 1882.

SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Will you please inform me if the following experiment is new:—I find that by adding about 5 per cent. of alcohol to the ordinary acid solution in a Planté secondary element that the action of forming is very rapid, and requires but an hour to develop a heavy oxide surface capable of taking a large charge.

My plan is generally to connect both lead plates to the carbon pole of several Fuller cells and a carbon electrode to the zinc pole, thereby developing both lead plates simultaneously. Afterwards I take out the carbon electrode and connect the lead plates to different poles.

I understand from Mr. Cuttriss, of the Duxbury Cable Station, that he, too, by the employment of a gas, has succeeded in hastening the forming action.—Yours, &c.,

Boston, May 8th, 1882. E. Berliner.

THE GRAMME MACHINE.

TO THE THE EDITOR OF THE ELECTRICIAN.

Sir: A circular has recently been sent round by the British Electric Light Company to the licensees for the sale and users of the dynamo machines made under the patents of Mr. C. F. Brush belonging to this corporation, claiming that the "Brush" machines are an infringement of the

Digitized by Google

"Gramme" patent, granted in June, 1870, having, therefore, about two years to run.

With reference to this circular, I am instructed by my directors to state publicly that this company is prepared to guarantee the licensees and users of the "Brush" machines against any such claims, which, they are advised, are utterly untenable.—Yours, &c. (for the Anglo-American Brush Electric Light Corporation, Limited),

WILLIAM CORDNER, Secretary.

Belvedere-road, Lambeth,
May 24th, 1882.

SWAN'S SYSTEM OF ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your interesting article on Mr. Swan's exhibits at the Crystal Palace you say (page 15 of your issue for 20th of May)—"We may say that with any incandescent system there is absolutely no personal danger from contact with the wires." Now, at the commencement of your article (page 14, second column) you say that Mr. Swan makes use of "machines with a higher internal resistance (than Edison) and lamps of a lower resistance." This, taken in conjunction with the context, means, I suppose, that Mr. Swan uses currents of high tension, which are, I believe, dangerous to life.

I am puzzled to know, therefore, how there can be no danger from contact with the wires of this system. It seems to me that the act of touching the two terminal screws of the little lamp illustrated on page 14 would give one a smart shock, if nothing worse.

I can understand that there may not be so great danger when all lamps are arranged in multiple arc, even with high tension currents, but even then surely there cannot be said to be "absolutely no personal danger;" and if the lamps are arranged in series I take it there is great danger attaching to incautious handling of the wires.

If you will help me out of my difficulty a favour will have been conferred on—Yours, &c., A TYRO.

CURATIVE ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Agreeing with what Mr. Desmond FitzGerald has stated "That magnetism exerts no physiological action whatever," I wish to make a few remarks on Dr. Shettle's letter in last week's *Electrician* on curative magnetism.

We all agree that the earth is a magnet, but Dr. Shettle bases many of his arguments on the assumption that the attraction of gravity and magnetic attraction are the same force. If gravity be due to the magnetic attraction of the earth, gravity ought to increase as we approach the magnetic poles of the earth, just as the dip of the magnet increases. But, according to Dr. Shettle's arguments, a piece of wood, a block of stone, a sheet of glass, and a human being have the same properties as a permanent magnet; they are all subject, in different degrees, to the laws of gravity; gravity is magnetism; therefore they must be all, more or less, magnets.

Dr. Shettle mentions his own case as the result of the curative effects of magnetism. He says he experienced great relief by placing a band, made up of a number of permanent magnets, round his waist when he was seized with the attacks he mentions in his letter. The curative effects of placing a belt made up of a number of pieces of cold metal round the waist of anybody suffering from a nervous complaint I have no doubt would be very efficacious in many cases. I have also heard of the curative effects of a cold smoothing iron, of wet cloths, of a bottle filled with cold water, and, in fact, of ice placed on the pit of the stomach of persons suffering from attacks of indigestion.

To prove the effects of magnetism on the human body, Dr. Shettle says, let anyone stand between a sensitive galvanometer and a permanent magnet, and observe the effect produced on the galvanometer when the poles of the magnet are reversed. The effect that is observed in such a case is due to the direct influence of the permanent magnet on the suspended small permanent magnet in the centre of the galvanometer coil. The fact that the magnetic rays pass uninterruptedly through the human body proves what Mr. Desmond FitzGerald has stated "that magnetism exerts no physiological effect whatever."

Dr. Shettle might place a sensitive galvanometer and a permanent magnet each side of a stone wall, say three feet thick, and observe the effect on the galvanometer upon reversing the permanent magnet above mentioned. He would find it the same, whether the intervening space between the permanent magnet and the galvanometer were a stone wall or a human being.

For the mere interest of the matter, I carried out the following very simple experiments, which appear to bear out Mr. Desmond FitzGerald's conclusions with regard to the physiological effects of magnetism.

I used an astatic mirror galvanometer, so sensitive that a current equal to ·0013 of a volt would register a deflection of one division, I placed a powerful permanent magnet about three feet directly behind the galvanometer, with its poles in the same plane. Several persons passed rapidly between the galvanometer and the magnet without causing the slightest change in deflection.

I afterwards connected thick insulated wires to the holes of the galvanometer, and led the ends about fifty yards away. Whilst somebody held the distant end of the wires in each hand a powerful permanent magnet was passed up and down his body, round his waist and chest, without causing the slightest galvanometer disturbance.—Yours, &c.,

H. C. DONOVAN.

Morden Wharf, East Greenwich, S.E.

LITERATURE.

Elementary Lessons in Electricity and Magnetism. By SILVANUS P. THOMPSON. Second Edition. [London: Macmillan and Co.]

This little work supplies a want long felt both by teachers and students, and occupies a position which no other work hitherto published has been able to fill. The book is well designed, and interesting to the general reader, while it carries the student by insensible steps far beyond the boundary at which non-mathematical students have hitherto been obliged to stop, and gives them, at least, a very useful insight into those realms which few, except trained mathematicians, have hitherto been privileged to enter; and though it has been found necessary to darken the glass somewhat lest the too great glory of that land should dazzle the eyes of those accustomed only to Nature's darkness, yet the dark glass has been so applied that facts appear in their true relations, and the introduction to the study of electricity as an exact science is made sufficiently inviting to induce the student to desire a further acquaintance with it and with the mathematical methods necessary for its development.

The division of the book into two parts, in the first of which the more elementary phenomena are described and classified, while their more thorough investigation is relegated to the second part, is very convenient both for teachers and students. The first part, comprising the first three chapters, constitutes an elementary course of study sufficient for the purposes of some readers, and forming an excellent introduction to the more advanced course which occupies the remainder of the work. In the latter part many of Maxwell's results are presented in a more elementary form than any in which they have hitherto been published, while, at the same time, the accuracy of the statements and of the reasoning upon which they are based is in most cases maintained. It may be questioned whether the very brief accounts of some of the most important electrical and magnetic measurements will be of much value to the student, especially when no caution is given respecting the great errors to which some of the methods are liable, *e.g.*, those for determining the internal resistance of a battery; but this merely indicates that

Digitized by Google

the whole of electrical science cannot be contained in a readable form in a pocket manual.

It would be of little value to the reader to enlarge further upon the good points of this useful little work. They will continue to be possessed by it, and will do much to advance the knowledge of the science. There are, however, a few points in respect of which we think slight alterations in future editions might be made with ease and advantage. Some of these we shall venture to point out, not detracting from the worth of the present work, but in the hope that its value may be increased in the time to come.

On page 9 it would be well to distinguish between *isolation* and *insulation*. A body is *insulated* when no electricity can enter or leave it. It is *isolated* when it is removed from the action of all other bodies. This distinction is useful, though not generally recognised.

The electrostatic unit of electricity is defined as "that quantity which, when placed at a distance of one centimetre from a similar and equal quantity, repels it with a force of one dyne." Now, this quantity will depend on the nature of the dielectric through which the action takes place, and to avoid difficulties in the future it is as well that the action of the dielectric should be at this early stage clearly recognised. The addition of the words *through air* to the definition will avoid the ambiguity and introduce the dielectric to the reader's notice. (The same remark applies on pp. 192 and 210.) A little later the dielectric receives full credit for the part it takes in inductive action, and on page 61 we are told that "the old theory of action-at-a-distance" is "logically unthinkable." This may be so, but it is dangerous ground on which to venture in an elementary treatise. Any hypothesis which leads to a deeper investigation into Nature's secrets is a step forward, and should be regarded as a scientific procedure. If, then, the introduction of a medium leads us to investigate the properties of the medium and the manner in which stress is communicated through it, we have, as Maxwell pointed out, made a step in advance, and the medium provides us with more to think about than the direct action theory; but whether the result ultimately arrived at is more "thinkable" than the other hypothesis we leave to professional *thinkers* to decide. There is, however, one point in connection with the action of the dielectric to which the attention of the student should be called. On page 61 it is stated that the glass of a Leyden jar is "squeezed between the attracting charges of electricity." Now, Faraday stated and Maxwell showed that there is a *tension* along the lines of force and a pressure (equal to it) at right angles to these lines. This is duly recorded later on in the book, but the student may have some difficulty in reconciling this with the statement that the glass is squeezed. Inasmuch as the material of the glass prevents the approach of the coatings to each other in obedience to their attraction, or, more properly speaking, to the tension of the dielectric between them, it must experience a mechanical pressure; but some light may be thrown on the matter by an illustration. Suppose two metal plates to be on opposite sides of a brick wall, but connected by stretched india rubber strings, which pass through holes in the wall. The wall, which prevents the approach of the plates, will be subject to pressure; but the elastic strings, which are the vehicle of the stress between the plates, and correspond to the dielectric, properly so called, are subject to tension. Remove the bricks and mortar, and the plates will approach one another, the strings contracting; remove the material particles of the glass, and the medium remaining will cause the armatures to approach, as in an air condenser, in virtue of its tension. In saying this, we do not imply that it is possible to remove the material particles of the glass without in some way modifying the dielectric, which is the vehicle of the electric stress.

On page 33 it is stated that the explanation of the fact that electricity resides only on the outside of charged conductors is to be found in its property of self-repulsion; "hence it retreats as far as it can from the centre, and remains upon the surface." This statement is, no doubt, put forward only as a partial truth; but the student is apt to infer that, so long as electricity repels itself, it will all go to the surface of conductors, whatever be the law according to which the force varies as the distance. Suppose a swarm of flies in a room all to repel one another, and that in virtue of the repulsion they recede to the walls, thus leaving the air perfectly free. It is surely conceivable that it would occur to one of the flies that, if he left the wall and took up his position in the middle of the room, he would then be farther from his neighbour than if he remained upon the wall, and other flies following his example might take up other positions in the room, so that the final state of affairs would be a surface distribution on the walls, together with a distribution through the air, according to some particular law. Whether this will take place or not depends upon the particular law of repulsion. If the repulsion varies as an inverse power of the distance numerically greater than the second, as, for example, the inverse cube, the flies would then be partly distributed through the air. If the student is at first led to believe that any law of repulsion will produce the same effect, he must fail to appreciate the argument which deduces the law of inverse squares from the experimental fact that there is no electricity within a closed hollow conductor.

The vexed question respecting the chemical theory of the voltaic cell and effects of contact of dissimilar metals is, unfortunately, still in such a position that an author is at liberty to enunciate almost any view he pleases respecting it, provided that he states clearly that the theory enunciated is simply his theory. We fail, however, to appreciate the reconciliation between the two theories supposed to be effected by the following statement (page 68):—"The real truth is that the electricity of contact and the chemical action are both due to molecular conditions of the substances which come into contact with one another, though we do not yet know the precise value of the molecular conditions which give rise to these two effects." This seems very like darkening counsel by words. Thomson's well-known experiment with the divided ring is quoted in support of contact electricity, but the result obtained by Mr. John Brown, of Belfast, who repeated this experiment in an atmosphere of sulphuretted hydrogen and found the potentials reversed, is not cited. The fact, as pointed out by Maxwell, is that the experiment only serves to determine the difference of potential of the air or other gas in the neighbourhood of the metals, and not the difference of potential of the metals themselves. The only method we have at present to determine the last-mentioned quantity is the measurement of the Peltier effect. In the "Contact Series of Metals," given on page 69, it is stated that the order is "in air," but no reason for this is assigned till we reach the foot note at the end of the chapter. On page 137 we are referred to paragraph 159 in order to learn "how the views of Volta and Faraday are to be harmonised." On referring back, as directed, we are disappointed at finding the harmony lie in this, viz., that the chemical and electrical behaviour of metals "probably both result from a yet undiscovered cause."

On page 126 we learn that when a plate of zinc and a plate of copper are dipped in water an electrometer will show that the metals and the water are all nearly at the same potential, but that if acid be added to the water it becomes slightly negative relative to the metals. We should be glad to know how the electrometer will prove this. An electrometer is capable of determining the difference of potential between two copper wires attached to the metals or between a copper wire attached to one metal and a second copper wire dipped into the water; but we know of no method of determining the difference of potential between a metal and an electrolyte. Even the Peltier method breaks down here, as Maxwell pointed out, because we do not know the exact nature of the chemical action which goes on in contact with the plates or the energy of the ions in the condition in which they are transferred through the liquid.

On page 81 we are told that "a fluid cannot propagate itself indefinitely without loss," and because a magnet can magnetise a piece of steel without losing any of its own magnetism it is therefore inferred that magnetism cannot be a fluid. We are far from wishing to maintain the contrary, but might not the same argument be applied to electricity on

Digitized by Google

account of the phenomenon of electrical induction, and is it conclusive in this case?

The notion of electric potential is very properly introduced at an early stage of the lessons, and on page 40 it is explained to be "the degree to which a body is electrified." No mention, however, is made of the fact that a body may be unelectrified and yet at a very high potential on account of charges of positive electricity on other bodies in the neighbourhood, or may even have a negative charge and yet be at a high positive potential. In fact throughout the earlier lessons the student gets into the habit of always associating positive potential with a positive charge on the conductor at that potential, and negative potential with negative charge, and he finds it more difficult to "unlearn" this erroneous knowledge (?) than he would to get the true idea of potential if properly presented to him at first. On page 193 we have the formal definition of potential, but in the foot-note on that page it is stated that "'potential' must be understood as 'power to do work.'" Surely this is confounding potential with energy. Potential is an attribute of a point in space, and a point may be at a high potential though there is no electricity there; it cannot, however, be said to have power to do work, any more than a *point* a thousand feet above the sea possesses energy in virtue of its position and of gravitation. Electricity possesses energy when at high potential, and energy is the product of potential and charge.

The proof on page 195 that $V = \Sigma \frac{q}{r}$ does not require the integral calculus to make it "*complete*," but only a very slight change in the form in which it is presented. A complete elementary proof will be found in Maxwell's "Elementary Treatise on Electricity."

The theory of thunderstorms, given on page 255, is the following:—The clouds consist of extremely small drops of water which have become charged with electricity by evaporation going on upon the earth's surface. "Suppose eight of these minute particles to join into one. That one will have eight times the quantity of electricity distributed over the surface of a single sphere of twice the radius . . . . and its electrical potential will, therefore, be four times as great." From this it appears to be inferred that the potential of the cloud will also be increased. Now, it is quite true that if the eight drops were the only drops in the neighbourhood, and they were made to coalesce after being a long way apart, the potential of the single drop would be four times that of the original drops; but the potential of any drop of water in the cloud, *due to its own charge*, is very small compared with that due to the charges of the other drops in the neighbourhood, and consequently its potential will be increased only by a very small percentage on account of the coalescence, while the average potential of the cloud itself will not be sensibly affected by the coalescence of drops in every part of it. If, however, the larger drops fall, so that the *mean density* of the cloud near its lower surface is increased, its potential there will also be increased.

In the preface we are introduced to an old doctrine under a new name, *i.e.*, "The Conservation of Electricity." Whether this is a happy title or not we leave to others to decide. The notion that electricity in moving through conducting wires behaves like an incompressible fluid was entertained by Cavendish. Long before he had the opportunity of perusing Cavendish's paper Maxwell taught that electricity behaves like an incompressible fluid, and that all electric discharges consist of currents in closed circuits. Thus in the discharge of a Leyden jar the same quantity of electricity passes across every complete section of the dielectric as through the external circuit, the difference in the two cases lying in the fact that in the wire the electricity has free course, while in the dielectric it can move only through very small distances. According to this view, when a charge of positive electricity is given to an insulated conductor through an electrode an equal quantity is squeezed out through its surface into the dielectric, and an electric displacement, diminishing in extent as the area increases, takes place across every section of the dielectric, till some neighbouring conductors are reached, from which (if they surround the charged conductor) an equal quantity of positive electricity is expelled. In fact, if any imaginary closed surface is drawn it is impossible to increase the amount of electricity within that surface. Now, the conservation of matter and of energy only teach us that the increase of the matter or energy within such a surface is equal to the amount which passes through the surface. The conservation of electricity teaches us that the quantity of electricity within the surface *cannot be increased at all.* But in respect of this principle, and of the unity of the nature of electricity, the book is by no means true to its colours. Of this many examples might be cited. The explanation of the action of the cylinder machine on page 43 is in the language of the two-fluid theory. On page 11 we are told that "the quantity of electrification produced is, however, by no means equal to the amount of the actual mechanical friction." The meaning of this we scarcely hope to discover.

Many other minor points we have noticed, some of which are misprints. Twice in the statement of a law the inverse power of the distance is mentioned instead of the inverse square. On page 116 the intensity of the magnetic field is expressed in dynes, though it is not of the same dimensions as force. In the statement of Maxwell's rule on page 158 the positive direction is not specified. On page 181 it is not made clear whether electric distillation is, after all, distillation or not. From the statements on page 230 a student may infer that it takes several hours to send a signal through a long cable. In reading page 181 we confess to a curiosity to know more of the "prodigious effect" of the electric shock on the monks.

THE FAURE ELECTRIC ACCUMULATOR COMPANY (LIMITED).

The first ordinary general meeting of the Faure Electric Accumulator Company (Limited), was held at the Terminus Hotel, Cannon-street, on the 23rd inst., under the presidency of Sir A. J. Otway, Bart., M.P.

The SECRETARY (Mr. Herbert Canning) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, as this is the first occassion on which I have the pleasure of meeting you here, allow me in my own name and in that of the board to offer you my congratulations on finding so large an attendance—so many gentlemen interested in what I do not hesitate to characterise as the greatest invention of modern times—one I believe calculated to effect a revolution not by any means inferior to those created, as to light, heat, and motive power, by the use of gas and by the discovery of the power of steam. It will be my duty as concisely and as clearly as I can to state to you the position of this Company, and our view of its prospects. If I should fail in making our position clear it will be open to any gentleman present to ask any question of me by way of obtaining further information, and on this you may rely, that as far as it is in my power he will obtain that information in a straightforward manner. Now, gentlemen, before I proceed on those remarks which are necessary to elucidate the position of the Company, and to describe the work of the administration over which I preside, it is absolutely necessary that I should make a passing remark on an incident, and on a publication which has appeared with reference to this Company, but I shall do so in no unfriendly spirit whatever. I desire to consider both the incident and the publication really as resulting from a somewhat excited brain, and I desire to deal with a business matter in a business-like spirit. One rule I have made in life, from which I hope I shall never depart, namely, not to allow personal feeling to interfere in a business matter, and where I have charge of the interests of others I feel that it is exceedingly easy to sink any personal uneasiness in relation to such matters. Now, the incident to which I refer—and I dismiss it in one word—was the circumstance that a large shareholder, indeed the vendor of these patents, thought it right to summon a meeting of shareholders a few hours previously to this meeting, which had been previously announced to take place. I need scarcely say that the meeting took the exact view which I anticipated that it would take. It is not usual in England, and I hope not anywhere, to pass judgment on statements till you hear them, and, therefore, the meeting deferred any opinion till they had heard the statement I shall make to-day. With regard to the publication. I really cannot treat these publications seriously, but it is my duty to say that I do not accept any of the statements contained in them as giving a fair and proper representation of the state of things in this Company. If it is necessary I am prepared to refute them, but I believe it would only stir up ill-feeling, and so far as I imagine it would not be productive of any advantage to the shareholders, the property, or the board that I should do so. I must, however, say this—and on this statement I think you may found my opinion of the whole indictment of the board—I must say this with regard to the conclusions to which the writer of those allegations comes, the conclusion he came to after a short statement was that the best thing this Company could do was immediately to go into liquidation. Well, to ask a company that has a very large balance at its bankers, that owes no one 6d., that has never made a call on its shareholders, and that has what it conceives a most valuable property, that is now carrying on and has entered into contracts for profitable business, and has prospects, as soon as ever it can obtain those articles it was formed to sell (accumulators), of a very large and profitable business—I say that to

Digitized by Google

ask a company under such circumstances to go into liquidation seems to me one of the strangest conclusions to which any man could possibly come. I now pass from all this to the consideration of what the Company is, what it has hitherto done, and what its prospects are. Gentlemen, this Company was not formed, let me say in a word, for gambling purposes. It was never the intention of the gentlemen who summoned me, any more than any one, to connect themselves with any company formed for that purpose. I can quite understand that gentlemen who have seen large fortunes made, and who will, perhaps, see large fortunes lost, in the gambling speculation going on at the present moment in electric light companies, are disappointed at nothing of the sort going on in this Company. Of course, really this Company was formed for a very important purpose—formed for the purpose of introducing to the public an invention, which, as I have said, I consider one of the most remarkable of modern times—an invention for the storage and distribution of electric energy to be worked under the patents obtained in this country by M. Faure. I have remarked on some process of the vendor of this patent, but let me say of that gentleman that he is a man of very remarkable ability and capacity, and one thing I entirely adopt is the very interesting memo he sent to me some time ago as to this patent, and that is the conclusion to which he comes—that the future belongs to electricity, that electricity must be worked by accumulators, that the accumulator Faure (that which we possess) is the only practical accumulator in existence, and that, although accumulators may and certainly will be invented, the Faure accumulator will hold its own, and that if it does not there is room for the Faure and other accumulators also. I adopt those conclusions entirely. I should have liked to give you a description of it, as there may be some who do not know what this accumulator is, but it would take far too much time. I wish, however, to state this—you find a most admirable description of the accumulator in a lecture given by Professor Ayrton at the London Institution in a little pamphlet which any one may possess. I propose from that pamphlet to select only one passage, as it deals effectively to my mind with an objection that was brought against the Faure accumulator as having disappointed some of the expectations formed of it. This is the quotation which I wish to read:—"When the Faure accumulator was first invented there were various suggestions of electricity being delivered at houses every morning like milk in cans, and the exaggeration of this idea no doubt did something to prejudice the cells in the eyes of the public. The reason why milk is delivered in cans and brought by carts is simply because the total quantity required is so extremely small. If milk were required to be consumed in large quantities like water is we should have it sent through pipes and not by cans. The main use of the accumulators will be as stationary reservoirs corresponding with cisterns for water or gasometers for gas. But in certain cases where the accumulators can be used to propel a cart, as in the case of tramcars—not the cart employed solely to carry the accumulators, then there is not the same objection to their being moved about, seeing that the total weight necessary is small compared with that necessary for a steam engine or a compressed air engine for tram lines to develop the same horse-power." In that sentence you have, to my mind, a complete answer to the only thing I have heard like disappointment expressed as to the Faure accumulator since it came to the public. I now pass to the work of the board and the constitution of the Company. When this Company was formed I must ask you to remember that we were dealing with an entirely novel invention. There was hardly anyone who knew anything at all about the accumulators, about their powers or their manufacture. We had, therefore, to look about us, and to see how best we could carry into effect the purpose for which we had come together, and for which we had invited the support of the public. We guided ourselves, in the first instance, by the advice of the gentleman who had great experience, to whom I alluded beforeas a man of great experience, as far as any one could have great experience of anything concerning accumulators—I mean M. Philippart—who was associated with M. Faure in the matter. He advised us as to the conditions under which we should proceed to supply ourselves with accumulators, and he recommended a very eminent firm in Liverpool, the firm of Fawcett, Preston, and Co., to be the makers of these accumulators, suggesting hereafter an idea which I think very excellent—that a construction company should be formed to develop the further construction and supply of these accumulators. Well, we entered into arrangements immediately with Messrs. Fawcett, Preston, and Co., and have succeeded in effecting a very good arrangement of a tentative character with that firm by which they are to supply us with a certain number of accumulators weekly on terms which will give what we consider a proper profit to the company. Our engineers, Professors Ayrton and Perry, went down to the manufactory of Messrs. Fawcett, Preston, and Co. last Saturday, and spent two days there, and reported that the manufacture of accumulators by Messrs. Fawcett, Preston and Co., which has only been quite recently started, is now progressing rapidly and satisfactorily, that over 300 large accumulators are now quite ready, and that the firm is now turning out 300 a week, and is arranging to deliver 1,000 a week if necessary. So much, therefore, for the work of Messrs. Fawcett, Preston, and Co. with regard to the delivery of accumulators. Well, gentlemen, we then said to ourselves that a necessary condition of a company such as ours was to be surrounded by men of acknowledged ability in the different branches they had to conduct. There was associated with the Company from its very beginning a legal firm which I do not hesitate to say stands second to none—Messrs. Freshfields. In all legal matters we have been guided by the advice of that firm. We secured the services of two gentlemen as scientific advisers whose names it is only necessary to mention—Profs. Ayrton and Perry, both of whom are here to-day, and we have secured their services on terms which I am perfectly sure the Company will consider satisfactory. We have a secretary who bears a name which is well known in scientific circles, and who is himself an efficient secretary; we have got a good staff, and we have obtained the services as manager of the Company of a gentleman who I do not hesitate to say is better qualified than any gentleman I know to manage matters connected with an accumulator company, in consequence of the large experience he has had in the company which first brought these accumulators to notice. He is now by my side, and I believe we shall find him a most efficient coadjutor and able manager. So much for the constitution of the Company. I have been connected now with powerful and successful enterprises in this city for many years, and I do not hesitate to say this—in none that I know of has there ever been so much attention given to the affairs of the company as has been given by this board, which has been styled an apathetic board. If I were to tell you the number of meetings this board has had you would be surprised. It will suffice, however, to say this—from the time we undertook the administration of your concerns there has not been a day, save Sundays, on which some members of the board have not met to consider the affairs of the Company, and how it could best be carried on. Well, gentlemen, we had at starting difficulties to meet. I believe any enterprise that is worth anything, that has a future, has, and must have difficulties to meet. It is, however, the duty of those concerned in conducting such an enterprise to overcome them, not to succumb to them. One of the principal difficulties was this—that when we were first launched into existence the public was skilfully prepared by mysterious paragraphs in newspapers, then by speeches delivered at banquets, and then by well arranged articles for the advent of another accumulator that was utterly to destroy and to replace this by its qualities. So that we did not feel that apprehension that some of our shareholders felt when all these mysterious paragraphs made their appearance. We adopted a very simple proceeding. We directed our solicitor to inquire the name of the writer, and also to take steps as far as was right and proper to proceed to action the moment that one of those accumulators that were so puffed and paraded were sold. We were advised that till certain proceedings took place we could not do more than take the first necesssary steps to defend our position. I must again do justice to M. Philippart, because no sooner was this assertion of ours challenged than he gave his name and address, and declared himself the author of certain allegations. No sooner was this new accumulator launched than we took steps that are necessary to protect the rights of this Company in the High Court of Chancery, and it is our intention to pursue these steps with all the energy that is necessary, unless we should be delivered from the necessity of war, by that which is always better than war, namely, a satisfactory peace. I presume that there is no one so fond of fighting that if he can get what he is going to fight for without fighting, he will not accept that. It is true that I have heard of some gentlemen who are never happy unless engaged in fighting, and, so fond are they of law suits, that when engaged in law suits with all their enemies, they will proceed to institute law proceedings with their friends and allies; but that is not our intention at all. We mean to defend the rights of our Company to the utmost of our powers, and to do so we have fortified ourselves by the advice of those who are most competent to give advice in such matters. First we have referred to a gentleman whose name will carry in this country the unquestionable weight of authority—we have referred to Sir Wm. Thomson, who has not the slightest doubt whatever that the accumulator of which we have heard so much is a direct infringement of our patent. We have fortified ourselves by legal advice, and have retained the services of most eminent gentlemen—I do not hesitate to say of gentlemen who are acknowleged to be most eminent in questions of this nature. We have retained the services of all these gentlemen, and as far as we have been able hitherto to gather legal advice, we have come to the conclusion that there is no question whatever that an infringement of our patent has been committed. If that is the case, all this advertising, all this puffing, is to our advantage. The more gentlemen prove that accumulators are necessary for all these electric light companies that are in the market, the more they prove our case. What could we desire more than that gentlemen should prove the necessity of accumulators, when we establish that we are entitled to everything that that accumulator does? We have but one thing, in my opinion, to be careful of, and that is to do nothing ourselves to damage our prospects. Of course, a house divided against itself cannot stand, and if people spread about ideas—ideas for which there is not the shadow of a shade of truth—that we are in any way doubtful of our patent rights, or the value of them, why no greater damage can be done to the prospects of this Company should such an absurd notion as that obtain credence. There is no foundation for it whatever. There is no one connected with this Company who has a right to have any doubt, because all authority we have applied to is against any doubt on that point. Therefore, our course is extremely simple. We have to defend our rights, and to establish them to the satisfaction of the proprietary, as I hope we shall by some means or another—if necessary, by proceedings in the High Court of Chancery. Now you will see, probably, what was your directors' programme, and I should like, in a few words, to tell you how far we have carried it out. Having associated ourselves with the gentlemen to whom I have alluded, and formed a company in the way I have related, we then asked ourselves, What are we to do? Well, the first thing was to get work—orders—and then get accumulators to allow us to carry out those orders. We thought we should do well if in starting we did this—if we got a public building, such as a very conspicuous and large hotel in which to use and show our accumulators; if we got the lighting of a well-known theatre, and showed the advantage of our accumulators; if we got the lighting of a very well-known and large private house in this country in order to show the value and use of our accumulators; if we succeeded in showing their value in the lighting of a railway train; and if we succeeded in showing their value in propelling a tram car. In almost all these things we have succeeded. In some of them we are actually at work, and in others we have contracts ready, which will be carried out as soon as ever we procure the accumulators. We have made an arrangement with the Grand Hotel, Charing-cross, an hotel sufficiently conspicuous to satisfy anyone, where our accumulators will very soon be seen at work. With regard to this, perhaps, you would like to know how far we have gone. The arrangements for the lighting of the large dining room at the Grand Hotel are now nearly completed, and this installation shows the enormous importance of Faure's accumulators, since it was made an essential condition that, as the engine room for the electric light is under a private dining room, the engine must not work during the evening. Hence, without the accumulators, the lighting of this hotel would have been impossible. We have also an agreement ready to sign at any moment with a most popular and conspicuous theatre—we could, indeed, sign them with several theatres if we were provided with the necessary accumulators. We have an agreement ready to sign and settle for the lighting of the private house of a nobleman very well known in this country, himself of scientific attainments, not very far from London. I do not know whether we shall be able to carry that out as soon as was expected. Here is, on my right hand, Mr. Edwin Freshfield, who presses us to light a church in which he is very much interested. We are quite

Digitized by Google

prepared as soon as we can get the accumulators to light his church, and if we light his church successfully there is no reason why we should not light St. Paul's Cathedral. As you are aware, we have for six months been lighting without any assistance the Pullman car train which runs three or four times a day on the railway of which I am a director. I am a constant traveller on the railway, and I am enabled to give an opinion as to the practical working of the light, and I unhesitatingly say that it gives satisfaction. I hear nothing but satisfaction expressed by the numerous people who travel by that Pullman train. We have propelled a tram car of a most unwieldly character; nevertheless, we sent that tram car at the rate of seven miles an hour, and I have no doubt whatever that we shall very soon be able to send a tram car at a speed very far exceeding that. The difficulty we have is a very simple one—it is really that we cannot execute the orders which are ready to be given to us. We cannot get the accumulators fast enough, but we do hope, either by a great development of the works of Messrs. Fawcett, Preston, and Co., or by the creation of a company for the purpose of their manufacture to overcome that difficulty, and then I really do not know what limit to set to the work which may fall to this Company. As far as I can get instructions from others I hold the accumulators to be absolutely necessary to the successful carrying out of the electrical enterprise that is before us. This is our statutory meeting, at which no accounts are laid before you, and no accounts can be laid before you, but I have given the best of all accounts in the account I have been able to give you by word of mouth. What I ask of you is to have confidence in the administration of this affair by those able gentlemen by whom I am surrounded, and my own impression is that they are fully competent (I do not speak of myself) to carry your affairs to a successful issue, and I know that it is their wish and desire to do so. There may be some of you who differ from that opinion, and may think that others could manage matters more satisfactorily. If that is so, by all means place them here. We are not the men to stand in the way of the success of the Company if it can be better arrived at by others; but so long as we retain your confidence, and the duty and responsibility devolve on us of conducting this great invention, it will be our duty and pleasure to devote such time and ability as we possess to the administration of your affairs in such a manner as I hope will have the result of bringing about a large profit to those who have joined in this interesting enterprise.

M. PHILIPPART then addressed the meeting, speaking in French, and

The CHAIRMAN afterwards stated that that gentleman had in his remarks acknowledged the entire honour of the directors, and that a meeting, such as that which he (M. Philippart) had convened on the previous day, though unusual in England, was not at all unknown abroad. He had also expressed his satisfaction at hearing the steps that the directors were now taking. He, however, appeared to think that they should have gone more quickly and made more progress. On that he might remark that sometimes those who appeared to go slowly went best. Under the circumstances M. Philippart had expressed himself as being very much at one with the directors. Half the number of shares asked for had been *bona fide* applied for and paid up—20,083 among 357 shareholders. They also had £10,000 at their bankers. They would consider with other proposals the proposal of M. Philippart as regarded placing the remainder of the capital. Replying to Mr. Keyser, the chairman repeated the work which the Company had done and were doing, and again stated that they could not complete the contracts to which he had referred, as they had not yet obtained the necessary accumulators. The first delivery of accumulators would be made that week. The making of these accumulators was very delicate work. The other Company had produced no accumulators. This Company had now 300 large accumulators ready at Liverpool; they would turn out 300 a week, and they hoped to have 1,000 a week if necessary. He considered that it might be wise sometimes to further their business to show a light from which perhaps no great profit was derived direct.

Professor AYRTON, in reply to another shareholder, referred with satisfaction to the result of the visit of Professor Perry and himself to the works of Messrs. Fawcett, Preston, and Co., and pointed out the advisability of a little delay in order to ensure the quality of the accumulators. The experiment in connection with the Kemp Town train was of enormous importance. In the lighting of the Brighton Pullman-car train the accumulators were charged by a fixed engine at Victoria, and a sufficient store of electric power was put into them to enable them to keep the whole train lighted on the journey from Victoria to Brighton and back again, including the waiting at Brighton. In the case of the experiments with the Kemp Town train the electricity was produced directly by the motion of the train turning a dynamo-electricity machine in the guard's van, and the surplus of the electricity which was not required to produce the light was stored up in Faure's accumulators on the train. Without accumulators such a system was absolutely impossible. This experiment had been thoroughly approved of, and the engineer of the Brighton Company was now making arrangements to continue it on a much larger scale.

A SHAREHOLDER inquired the number of accumulators which would be necessary to enable the directors to declare a dividend.

The CHAIRMAN replied that that was not a question for a statutory meeting, and the directors had not gone into it.

A SHAREHOLDER stated that it was said that the excessive weight of the Faure accumulators was a great objection to them, and that the advantage of those who were pirating this Company's invention obviated that objection.

The CHAIRMAN replied that the weight of the accumulator for lighting the Pullman trains was 15 cwt. (not three tons, as the shareholder stated he had been informed). It was difficult for him to say whether the other company's accumulators were so light, as he had not seen one.

A vote of thanks to the chairman closed the proceedings.

THE ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on the 25th inst. at the Cannon-street Hotel to consider the agreement referred to at the meeting of the Direct United States Cable Company, which is fully reported in this issue.

The SECRETARY (Mr. T. H. Wells) having read the notice convening the meeting,

Viscount MONCK, who presided, reminded the propietors of the policy which he referred to on the last occasion as that which they were then pursuing experimentally, namely, that of reducing the tariff to a low rate, with the object of increasing the traffic so that all the cables would be filled. He was now able to state that the experience of that policy was not sufficiently encouraging to induce them to persevere in it. The Jay Gould cable having become an accomplished fact, they had felt it judicious to come to the agreement which the shareholders had been called together to consider. He then proceeded to remind them that the directors had no control whatever over new competitors springing up, but observed that as far as any agreement could do so, this arrangement would guard them in the future against fresh competition. The proportions in which the traffic was to be divided had been regulated by their reference of what the cables would take in competition, without reference to agreements at all.

The SOLICITOR, at the request of the chairman, having read the heads of the agreement.

The CHAIRMAN moved its approval.

The MARQUIS OF TWEEDDALE seconded to motion.

A discussion followed, to which the chairman replied, and the motion was then declared carried, with three dissentionts.

A vote of thanks to the chairman brought the proceedings to a close.

THE DIRECT UNITED STATES CABLE COMPANY (LIMITED).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel, Cannon-street, on the 25th inst., "to consider, and, if approved, to confirm and adopt an agreement made between this Company, the Anglo-American Telegraph Company Limited, La Compagnie Française du Télégraphe de Paris à New York, and the American Telegraph and Cable Company, with respect to the division and appropriation of the traffic receipts. By this agreement, taken in connection with the existing agreements between this Company, the Anglo-American Telegraph Company and La Compagnie Française du Télégraphe de Paris à New York, the joint receipts of the four cable companies will become divisible in the following proportions:—From the date at which the American Telegraph and Cable Company shall have one cable in complete working order and condition, and regularly opened for traffic:—18·375 per cent. to the Direct Company, 55·125 per cent. to the Anglo Company, 14·000 per cent. to the French Company, and 12·500 per cent. to the American Company, and from the date at which the American Telegraph and Cable Company shall have two cables in good working order and condition, and regularly opened for traffic, the division of traffic receipts will be in the following proportions: —16·275 per cent. to the Direct Company, 48·825 per cent. to the Anglo Company, 12·400 per cent. to the French Company, and 22·500 per cent. to the American Company. The above division of traffic receipts is subject to certain modifications in the event of interruption of the respective cables."

The SECRETARY AND TRAFFIC MANAGER (Mr. J. W. Fuller) having read the notice convening the meeting as above,

The CHAIRMAN said: Gentlemen—Before putting the resolution which we have invited you to come to approve to-day I shall make a few remarks, so as to give you a fair idea of the present position of things and our reasons for entering into this agreement. We have called you together to-day for a special purpose. This is the third time that I have had the honour of addressing you at an extraordinary meeting. The first was to ask your approval of a joint-purse arrangement with the Anglo-American Company. That has been carried on for some time, and, I believe, with very fair success. The second, to ask your approval of an arrangement of a similar nature with the French Company; and now, for the third time, to ask your approval to probably the most important of all, I refer to the joint-purse agreement which we have just completed with the American Telegraph and and Cable Company, and we have also made a working arrangement with the Western Union Land Telegraph Company, a company to which I alluded at our last half-yearly meeting. At that meeting, you will remember, I gave you a considerable amount of information, not only on the subject of the 1s. tariff, but also of the formidable opposition which we were about to meet. I also indicated that a great deal of time and money might be required to maintain our contracts with the various land-line systems in America with which we had traffic arrangements, viz., the Atlantic and Pacific and the Franklin Companies in the United States and the Dominion Telegraph Company in Canada; and these companies, having been brought under the control of the Western Union Company, made the difficulties still more complicated, and gave us a still more powerful combination to contend with. I foresaw in this a very formidable competition, lower dividends, and vast law expenses, and I may tell you, gentlemen, that expensive as law is in this country, it is still much more so on the other side of the Atlantic. Therefore, it became a serious question whether it would not be desirable to come to some arrangement if one of an honourable nature could be come to, beneficial alike to this Company and to all parties. (These are the reasons which induced us to go into these negotiations, because we know perfectly well that competition means lower dividends, and in many instances no dividends at all. The dividends we have been paying have not been by any means excessive, and it is our desire to maintain for this Company, as we have from the time we became directors of it, a uniform dividend. This we have done at 5 per cent., and this I hope, through these arrangements, we shall be able to continue to pay to our shareholders.) Our first attempts in that direction failed, but there was an evident desire on the part of the American Cable Company and of Mr. Jay Gould, who created it, that some understanding should be arrived at. I have always held that arrangements between telegraph companies are desirable where they could be mutually beneficial. Well, gentlemen, negotiations were reopened, and the result is the agreement now submitted to you, which I hope will prove satisfactory. I am therefore before you to-day to ask you to sanction it, and before doing so I think it right that I should give you a slight sketch of the companies with whom the working arrangements are

Digitized by Google

entered into. The Western Union Company has the control of the telegraphic system of the whole of the vast territory of North America, including Canada, representing a capital of upwards of sixteen millions sterling. To form an idea of the enormous extent of their system I may mention that the length of wire owned and controlled by them is 327,171 miles. You will better realise this when I state that the total length of wire of the British Post Office system is 116,680 miles, and I may also mention that we have the assurance that if direct land wires are required between the sea board and the important cities of America, so as to give every possible facility to submarine telegraphy, they will be constructed by the Western Union Company, and I may tell you that such is our confidence in the power of that Company that we have made it part of the arrangement that they shall take over during our pleasure our offices in New York and work our land lines between there and our cable termini at their own cost, and I may say, gentlemen, that this bargain will, I believe, benefit our exchequer to the extent of some thousands a year. Of course, if any competition should arise which would necessitate our taking posession of our offices again we are at perfect liberty to do so, and we have reserved to ourselves the right to do so; but, having such a powerful connection on the other side to protect our interests there, we do not anticipate any competition that will require such a change. You will see, gentlemen, from these arrangements that we have secured a very powerful ally in America—so powerful, that they will be bold indeed who will attempt to lay down cables to America in the face of a company possessing the whole control of all the land telegraph systems both of America and Canada. But no doubt we shall hear of such competition. Indeed, only a day or two ago I heard of another company which was to come out with a 9d. tariff, which, after allowing for outpayments, would only leave about 6d. as the cable company's proportion. Now, gentlemen, we can speak with some confidence on this question of rates. We have given the 1s. rate nearly a year's trial, and we find that had we gone on for another year we should not have been able to declare the dividend, moderate as it is, which we have done since this Company was reconstituted. We have also the experience of the French Company, who are under the control to a great extent of the Telegraph Department of France. Before that Company changed the tariff from 1s. to the present rate of 2s. they were obliged to satisfy the Minister of Telegraphs that the 1s. rate was unremunerative; and I believe, though I have not been officially informed, that the advice of the Government accountant who was sent to inspect their accounts was that they ought to charge 3s. instead of 2s. per word if the shareholders were to receive such a return as they were entitled to expect. Mr. Jay Gould also discovered that a 1s. tariff would not give a fair remuneration on such a property as this. As evidence of this you will remember that while we were working at 1s. he opened his cable at a 1s. 6d. rate; and, finally, he intimated to us that, even if no arrangement were made, the 2s. tariff was the one which ought to be adopted. These arrangements have led to our resuming the 2s. tariff. I may mention, as a justification of this step, that during the whole of the time the 2s. tariff was in force we never had any complaint from those who used the cable, and were, therefore, principally concerned; and I find now that the tariff has been advanced, that a similar feeling of satisfaction has been expressed, and for this simple reason—that a 2s. tariff as against a 1s. in large commercial operations is but a very small percentage upon the operation itself, and, consequently, rarely influences in any way the number of telegrams forwarded. If we had found by experience that the 1s. tariff would have given us such an amount of traffic as would have secured to us the very moderate dividend that we have hitherto been able to pay you, we should have continued at the low rate, but strange as it may seem, our experience with the 1s. tariff has been that even lately, instead of the traffic showing a growing development, it has actually diminished. That is a very remarkable fact, and it is well that you should know that the 1s. tariff has not induced the amount of traffic we naturally expected. I may say further—for I believe in very considerable progress in the submarine telegraph system—that, had we continued at the 1s. tariff till we got as much out of that tariff as we are now getting out of the 2s. rate, it would have cost the combined cables something like £2,000,000 sterling. That is a very important fact, and it is one that the public should understand as well as the shareholders, and I mention it as showing that we are carefully watching your interests, and trying, as far as we possibly can, to maintain not only an efficient system of telegraphy, but, at the same time, pay a moderate dividend to our shareholders. There would be nothing so dangerous as to render telegraphs unremunerative. I do not exaggerate when I say that three-fourths, and probably nine-tenths of the trade of the world is carried on by the aid of submarine and land telegraphy. The commercial world could not live without it; the political world would be in a state of tension, and commercial enterprise would suffer greatly were these cables interrupted, or were the companies placed in the position of having worn out cables, and no reserve wherewith to replace them. Therefore, it is in the interest of the public, of governments, and of the commercial community of the different countries of the world—aye, and of social life, that these submarine systems should be maintained, and maintained so as to give a moderate dividend to the shareholders. I believe now that this combination just completed makes it the most powerful of its kind in the world. I believe that those on the other side of the Atlantic, with all their natural enterprise, are with ourselves earnestly interested in giving their first consideration to having a thorough, complete, and efficient service. I may, I think, without any breach of confidence, read a telegram which I have received among others. It runs as follows:—"Gould, New York, to Pender, London. I have received your message advising me of the execution of the cable contracts. I am greatly pleased that they are finally settled, and hope and trust they will prove profitable to all interests, and this result can beyond doubt be achieved if we only pull together strongly in the line you indicate of improving and perfecting our international exchange of telegraph business." Now, while I have said that this is perhaps the most powerful combination ever entered into, some might call it by an ugly name, and say that it is a great monopoly; but I hold that there is nothing of the monopoly character in it. You cannot call a system of combination which gives an efficient service to the public, and only yields a 5 per cent. return—you cannot call that monopoly, and therefore I say that the public, whose interests should be protected as well as those of the shareholders, are largely benefited at the present moment by the combination which has just been completed. I have, therefore, shown you gentlemen that in all these negotiations the interests of the telegraphing public have been carefully considered. I also hope that this new arrangement will enable us to maintain at least the 5 per cent. dividend, and such a reserve fund as will make our property permanent by providing us with the means of replacing our cable when it should cease to live. I have said in a previous part of my remarks that I believe three-fourths, if not nine-tenths, of the whole of the business of the world is carried on by the aid of submarine telegraphy. As proof of that I have been watching the negotiations in respect of the present agreement and arrangement, all of which have been carried on by cable; and most important negotiations you will admit they are, representing or involving, as they do, a capital of over ten millions sterling. The speed, the accuracy, and the time saved has astonished me, although I have been so long connected with submarine telegraphy; and I was amazed that human thought should be so rapidly transmitted and retransmitted, so that a lawyer sitting here one day had in the morning an answer to the points dealt with on the previous day. All this leads one to believe that telegraphy has now got such a hold of the various interests of the world that it is simply impossible that they can do without it, and that its progress is as certain as that the sun appears in the heavens. As an interesting fact in connection with our cable, and showing the celerity with which events can be communicated across the Atlantic, I may mention that the name of the winner of the Derby race yesterday was transmitted from our London office to New York in 35 seconds. I have given you a little, I hope, pleasant information on the subject of telegraphy. I have shown you that we are attending to your interests in making this arrangement. I cannot say that no other company will come forward to compete; but I say that any other company now attempting to compete with those who have the control of the whole system of America will regret it. As a gentleman has said to me, I should like to sell the stock in that company at 50 per cent. discount the day it comes out. It is impossible that it should be a success without an enormous sacrifice of time and money; and as to waiting till telegraphy increases so as to give a return on the amount of the fresh capital invested, the only view I can take of it is that it would be a folly that does not exist in the mind of any man at the present moment. With these remarks I shall ask the solicitor to read the heads of the agreement we have entered into with the American Telegraph and Cable Company.

The Solicitor (Mr. John Mackrell) having accordingly read the principal features of the agreement,

The Chairman, continuing, said: Now, gentlemen, you have heard the heads of the agreement read, and I shall, therefore, read the resolution. If any gentleman has any remark to make upon the heads of the agreement or the observations which I have just made, I shall be glad to hear him and to give him the best answer I can. The resolution is:—"Resolved. That the agreement now submitted to this meeting, dated the 12th May, 1882, and made between the Anglo-American Telegraph Company Limited, the Direct United States Cable Company Limited, and La Compagnie Française du Télégraphe de Paris à New York of the first part, and the American Telegraph and Cable Company of the second part, be, and the same is hereby, ratified and confirmed, and that the directors be, and they are hereby, authorised to carry the same into effect."

Mr. W. Ford: I beg to second that.

The Chairman: If any one desires to make any remarks I shall be very glad to listen to them now.

Mr. Jackson: Without occupying much time I should like to say something with respect to this agreement, or rather with reference to the prospective policy of the united board under the circumstances of this arrangement, which you have designated, and which we must presume generally is, a very powerful combination—the most powerful yet attempted by the Atlantic Telegraph Boards. Viscount Monck said to-day that the policy of the Anglo-American Board was to secure to their shareholders a moderate or fair dividend with the lowest possible tariff, and I think that that is the principle on which the united companies should act as anticipating, or rather as preventing that competition which you decry, and which we, no doubt, would have very much suffered from in the establishment of these two new cables had not such an arrangement as this been come to. If you could publicly state—and I wish it had been so stated at the Anglo-American meeting—that after a fair and moderate dividend on their stock, the policy of the companies would be to reduce the rates, and not to take advantage of the possible consequences of this organization, it would have a beneficial effect. Though you may say that the object of the boards of these companies is not monopoly, yet still it could be worked as a monopoly under favourable circumstances. It is to be presumed that a fair dividend on the general capital of the companies could be obtained at a 2s. tariff in a very moderate period even. There is a very considerable amount of capital to come in to share those receipts. The enumeration by you of such a policy, which I believe is the feeling of the board of this Company, that a moderate dividend and sufficient reserve for renewals would satisfy them, and that they would be prepared to share with their customers any further increment of dividends in the reduction of tariffs, would, I am quite sure, be the only policy which, under the circumstances, could stop that extraordinary speculation or enterprise which is ready to float Atlantic telegraph companies with the certainty of 50 per cent. discount of their capital to which you have referred. You know better than me, but it is perfectly certain that, notwithstanding that discount, national susceptibilities have to be satisfied. The French nation would not be content to have its messages carried over a friendly line of another country; Germany felt the same; and the principal source of our revenue—America—held the same view. Well, these great countries, which represent the bulk of the trade carried over these cables, are now in possession of their independent lines, and I think that the ground for competition has very much been cut away; but still, once take advantage of a possible position, and seek to pay the same dividend as a water or gas company, competition will again be encouraged. The Anglo-American Company paid 9 per cent. in 1870. I know that, for I had the pleasure of receiving it, and in 1872 that company paid 10 per cent. and a bonus of 2 per cent., but then it had a monopoly. There was no competing line. If the directors of these united companies should be tempted to take advantage of their position I hope you will say that it is not only the intention but the resolution of this Company to be satisfied with a moderate dividend and sufficient reserve for renewals, and that any benefit beyond that from this arrangement will be divided among their customers. I think that that

Digitized by Google

decision would be most important in preventing the competition which you have so often decried.

The CHAIRMAN: Gentlemen: When we gave the 1s. rate, we did it with the honest desire to benefit the large telegraphing public, and to satisfy ourselves as to whether that would be a remunerative tariff for the shareholders. As I told you in the few remarks I addressed to you, we found that that 1s. rate not only did not give us a return, but that looking at the percentage, looking at the progress made, it would have taken five years before the 1s. rate would have given us the same return as the 2s. rate. You would, therefore, have required to spend over £2,000,000 sterling to get the return from the 1s. which we are now getting from the 2s. tariff. Of course, even at the end of the five years, it is difficult to say whether we should have got it or not. We are as anxious to have low rates and large traffics as any one. We have tried very high rates. We had a considerable period of 4s., and a considerable period of 3s. We then went down to 2s., 1s., and at one-time 6d.; but watching carefully the different rates, we think that that which is not considered at all too high by the telegraphing public is the 2s. tariff, and we consider that that rate is one which will be fairly remunerative. We, therefore, decided at the present moment to make that the tariff. If there should be such a change that we conceive it would be better to lower the tariff, we have not made a rule which cannot be broken to-morrow. The real question for us to consider is the rate that will be most satisfactory to the public, and at the same time give a fair return to the shareholders. As to what we call the *amour propre* of France and America, France was determined to have her cable, and she has got it. With regard to America, what has astonished me, as I have said at previous meetings, was that the Americans were so long without a cable of their own. They have an enormous traffic between this country and America, and I have often thought why they did not have a cable, with their capital and enterprise. However, they left us to do the work. We have been the pioneers and leaders in every way. They have now chosen to come in, and I do not see any harm in letting them have a fair proportion. The proportion they are now to receive is not the full proportion for the two cables which are to be made. In another year we may, after all, find that we are strengthened by these two new cables instead of being what I call lessened in our dividend. I am quite hopeful that with the tariff we have now fixed we shall get such a return as will enable us to continue our 5 per cent. dividend, and maintain the reserves which we have provided hitherto. I have spoken of *amour propre*, and it was said that Germany had some idea in the some direction. There is now direct telegraphic communication between Germany and New York, *viâ* the Atlantic system of telegraphy, by the submarine telegraph just completed between Emden in Germany and Valentia in Ireland. Germany, therefore, without coming through London or France, has now her own cable between Germany and New York. Therefore, we have met the *amour propre* of these countries. Each country has communication with New York, and I am hopeful, looking at the combination now formed, that we shall have a little peace in the Atlantic for some time. At all events, what we have done to-day is in the belief that it was better to do that than in competition throw away a large sum of money, and probably disgust our shareholders as well. With these remarks I will now put the resolution. Those in favour of it will please hold up their hands. To the contrary. Carried unanimously. I am obliged to you for your attendance to-day, and I believe I may congratulate you on what I believe is a very fair arrangement in the interests of all concerned.

Mr. JACKSON: Before we separate I think that a vote of thanks is certainly due to our chairman on this occasion. I think, too, that our prospects are brighter than they have been for some time. I move that our best thanks be given to the chairman and his colleagues.

A SHAREHOLDER seconded the motion, and it was carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I thank you. You may rest assured that there is no part of your interests that we are not watching carefully, and this has been a very anxious time. These negotiations have been going on for six months. Every point has been fought carefully, but I hope and believe in a spirit of bargain so fair that both parties are satisfied with it.

The proceedings then terminated.

THE LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).

The annual general meeting of this Company was held last week at the offices, Old Broad-street. Mr. Pender, M.P., presided, and, in moving the adoption of the report and the payment of a dividend of 3s. a share, stated that the revenue of the past year had been £18,300, showing a decrease of £2,800, as compared with the previous year. This decline was attributable to the undue competition of the land lines of the Brazilian Government with the cables of the Western and Brazilian Telegraph Company, upon whose traffic this Company depended for their dividends, and also to the frequent interruptions of the cables of that Company. It was satisfactory, however, to know that the Western and Brazilian Company were putting all their cables into efficient order, and they had recently re-established communications with Para, a most important station. The debt of the Uruguayan Government had increased from £7,443 to £8,311, but any portion of the land-line receipts not already collected had not been considered as profit. He thought they would in time be able to realize that debt. An anonymous letter had appeared in *The Times* commenting on the honorarium of the directors. As he stated at their last meeting, the directors had voluntarily reduced their fees. They had, he asserted, positively rescued the concern from ruin, and for the trouble in connection with doing so they had received £300. When the undertaking was re-established and it was made an English company they put aside to a reserve fund a portion of the honorarium which was granted to the directors on the formation of the Company. The Western and Brazilian Company were now negotiating with the Brazilian Government as to taking over their system, which included this Company's; and, should a satisfactory conclusion of those negotiations be arrived at, it might be necessary to call another meeting.—Mr. Hollocombe seconded the motion.—Mr. Robinson Kendal contended that dissatisfaction was felt at the amount of the directors' fees, which, he said, represented one-ninth of the entire net revenue of the Company. He urged the amalgamation of the Company with the Western and Brazilian Company, and concluded by moving an amendment to the effect that the dividend be paid, but that, instead of adopting the report, the meeting be adjourned to enable the directors to alter the Articles of Association so as to reduce the annual remuneration of the directors from £1,200 to £600.—Mr. Roberts seconded the amendment.—The chairman, in replying, stated that the directors were quite agreed as to the advisability of an amalgamation with the Western and Brazilian Company, for which object negotiations had been going on, but it was a question of terms, and they were determined to maintain the preferential position which this Company enjoyed compared with the other Company. Their remuneration was not £1,200 but £1,000. In reply to questions he said the capital cost of the land-lines had been £90,000, and, as they were efficiently maintained, it was not so necessary to make provision against their depreciation as in the case of submarine lines. The Company, too, was only just emerging from its troublous into a prosperous condition. The debentures would fall due in 1884, and he hoped they would be able to renew them on more favourable terms. He then put the amendment, which he declared lost on a show of hands, and afterwards put the resolution, which he declared carried.—A poll was demanded by Mr. Kendal.—The retiring director and auditors were next reappointed, and the poll was afterwards taken, with the following result:—In favour of the motion and against the amendment, 12,860 votes, to 1,718 of which a technical objection had been urged; and against the motion, and in favour of the amendment, 7,735.—The chairman, therefore, declared the amendment lost and the resolution carried.

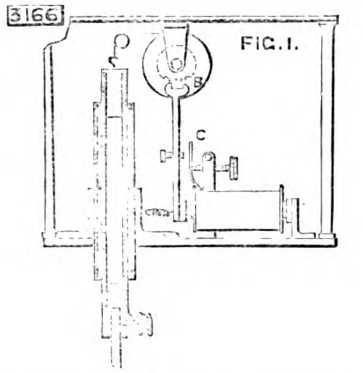
RECENT INVENTIONS.

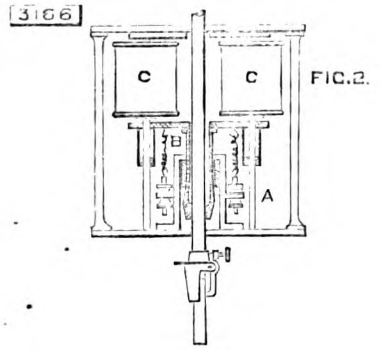
ABSTRACTS OF SPECIFICATIONS.

3166. ELECTRIC LAMPS, *W. Morgan-Brown, London.—20th July*, 1881.—(*A communication from G. P. Harding, Paris.*) 6*d*.

In one form of lamp, to regulate the arc the inventor uses an escapement, B, actuated by a



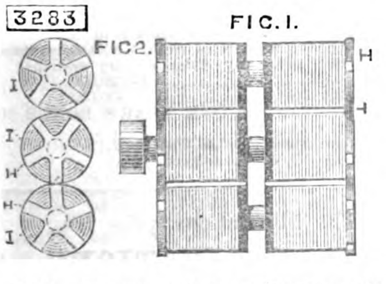
shunt brake, C, the escapement being arranged with a recoil action giving falls of precise mea-



sure to the carbon. A second form is a modified clutch lamp, in which a cone clutch, A, is fixed to and forms part of an armature, B, actuated by magnets C C.

3283. IMPROVEMENTS IN ELECTRIC GENERATORS, *S. Pitt, Sutton.—26th July*, 1881.—(*A communication from S. J. M. Bear, Mitchell, Iowa, U.S.A.*) 8*d*.

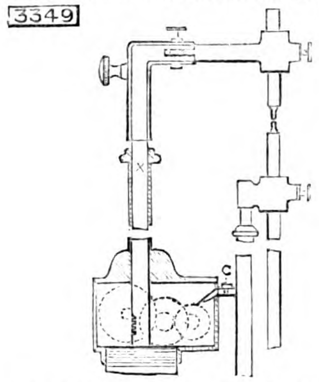
The object of this invention is to construct a machine in which the poles of the armature and the field magnets may be brought into the closest proximity, or even absolute contact with each other, without lessening its efficiency. Figs. 1 and 2 show a machine of this kind, the three straight electro-magnets, having their cores parallel. These cores are provided with polar exten



sions H H. The spaces between H H are filled with non-magnetic material I I, to complete a solid disc at each end of each of the magnets. The magnets are assumed to be mounted in a frame, so as to allow the revolution of each magnet about an axis concentric with its core, with the solid polar discs at their extremities either in actual contact or close proximity. Fig. 2 shows the angular position of H H with reference to each other. Various modifications of this machine are described.

3349. IMPROVEMENTS IN ELECTRIC LAMPS, *A. W. L. Reddie, London.—2nd August*, 1881.—(*A communication from D. A. Chertemps, Paris.*)—6*d*.

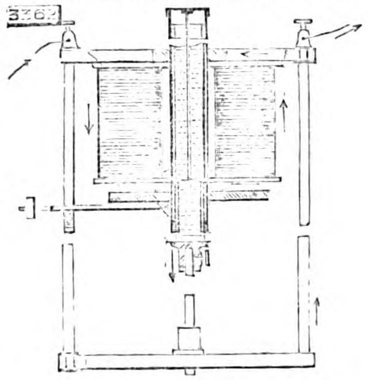
The construction of the lamp will be seen from the figure. The arc is formed by the lower carbon holder being drawn down by a solenoid not shown; spring pawl G will then arrest the motion of the



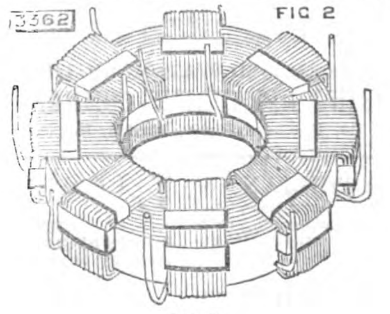
clockwork until again set free, when the rack rod X will be free to descend and bring the carbons into contact. The two screws shown permit of the adjustment of the upper carbon sideways, and also of the regulation of the arc.

3362. IMPROVEMENTS IN ELECTRIC LAMPS, &c., *J. Hopkinson, F.R.S., London.—3rd August*, 1881. 6*d*.

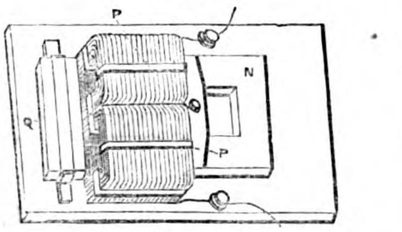
The upper carbon is carried from the armature of an electro-magnet, not rigidly, but by means of a catch, which, when the arc becomes too long, is



liberated by the action of the armature. The motion of the carbon is controlled by the fluid contained in the upper carbon holder. Fig. 1 explains the construction of the lamp, the arrows



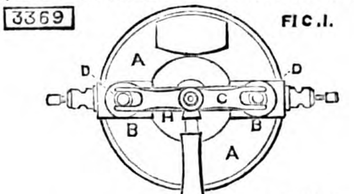
FIC.3

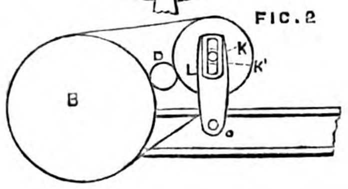


representing the direction of the current. The inventor also regulates the current supplied to any lamps by an adjustable self-induction coil. Fig. 2 shows one form of this coil. A ribbon of thin sheet iron is coiled into an annular form, there being a layer of insulating material between the overlapping portions or layers. Round this ring copper wire is coiled as shown. These coils are connected with plates, into which contact plugs connected with the main wires can be inserted, so as to place one or more coils in circuit. The ring may be cut in half in order to be able to place the copper coils in it, and subsequently joined. Fig 3 shows another form of this current regulator. The action is as follows:—When electro-magnet N is drawn from coils P and is at a distance from armature Q, the coefficient of self-induction is small, and as it is thrust in and approaches the armature the said coefficient increases. If a lamp be in circuit the current through lamp is diminished as N is thrust into the coils of P.

3369. WORKING GEAR AND APPLIANCES USED IN ELECTRIC LIGHTING, *K. W. Hedges, Westminster.—23rd August*, 1881. 6*d*.

This invention relates to such things as switches and driving gear. The switch, Fig. 1, is fitted between the contact pieces by insulating material A A, and from the end of the lever a loose con-

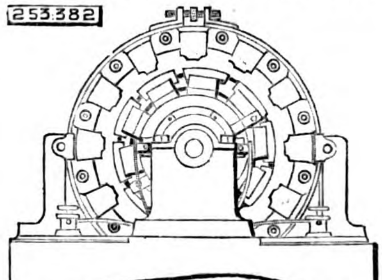




tact piece D, which can be moved as it wears the contact piece B. Fig. 2 shows the arrangement for driving the shaft of machines, where B is driving pulley, D that on machine, and L an idle pulley on spindle K[1] on block K.

253,382. MAGNETO-ELECTRIC MACHINE, *Ludwig Herman, Union, N.J., assignor to himself and Julius Jonson, New York, N.Y.—Filed May 13th*, 1880.

Brief.—An armature mounted on an excentric driving shaft is brought in contact with or in close proximity to the field-of-force magnets. The magnets are parallel with the shaft, and the entire body of the armature is wound with conducting



wires in the direction of rotation. Pole pieces are provided at the ends and in the centres of armature and field-of-force magnets. The electrical connections are such that the field magnets at one side of the point of nearest approach of the armature are of one polarity and those on the other side of the opposite polarity at all times.

255,497. INCANDESCENT ELECTRIC LAMP, *Phillip H. Diehl, Elizabeth, N.J.—Filed January 10th*, 1882.

Claim.—(1) An electric lamp consisting of a hermetically-closed glass globe, a light-giving part inside of the globe, a secondary coil supported within the globe and placed in circuit with the light-giving part, and a primary coil arranged exterior to said globe and in inductive relation to the secondary coil, substantially as set forth. (2) The combination of a glass globe containing the light-giving part, an extension made integral therewith, and secondary coil supported at the interior of the extension and placed in circuit with the light-giving part, and of a primary coil arranged exterior to the globe and in inductive relation to the secondary coil, substantially as specified.

THE EXCHANGE TELEGRAPH COMPANY, LIMITED.

Head Offices--17 & 18, Cornhill, E.C.; Stock Exchange, E.C.; 27, Regent Street, W.

Incorporated the 28th March, 1872, under the Companies Acts of 1862 and 1867, and by Special License from H.M. Postmaster-General.

This Company will undertake to supply recording instruments, telegraphically connected with the Stock Exchange, by the aid of which Subscribers, at their respective offices, may be kept continuously advised throughout the day of the constantly occurring market fluctuations in stocks and shares.

Instruments are placed in the offices of Subscribers and kept in order by the Company, free of every expense but that of rent, and inspectors visit them daily to supply ink and paper.

Terms: £50 per annum, payable quarterly in advance.

Applications for instruments to be made to the Secretary at the above address.

Not having any springs or clockwork to wind up or to depend on, these instruments are acknowledged by those familiar with the system of telegraphy to be the only instruments yet invented that are capable of doing the work required of them continuously for a lengthened period, as evidenced by the fact that the Gold and Stock Company of New York, having the monopoly of this kind of business in the States, and which owns all the patents of the day of any value, has, after due trial, discarded all others.

The Company is prepared to treat with provincial Companies requiring instruments for the delivery of news for either single or double wire systems under the Company's patents, whereby from central stations identical information can be simultaneously delivered to any number of recipients by automatic, self-adjusting, printing instruments requiring no local batteries, no winding up, and no knowledge of telegraphy on the part of the receiver, the printing being in bold roman type, and the propulsion of the paper being effected by the electricity supplied from the Central Office.

The instruments supplied by the Company can be had to work either on single or double wires, and to print either on a slip or tape of paper, as has hitherto been the custom, or on a broad band of paper in column form.

The system has been in use by the Exchange Telegraph Company (Limited) in the City and West End of London since 1872, and by MacMahon's Telegraphic News Company (Limited), for the delivery of Parliamentary, Sporting, and General Intelligence, since 1879.

The Company will supply householders and others with its

DISTRICT CALL SYSTEM.

By the aid of a small automatic telegraph instrument a Subscriber can at any hour, day or night, call a messenger, cab, or policeman, or give the alarm of fire, and will obtain the required assistance within three minutes of making the signal. Subscribers, when absent from their homes for a season, can leave their houses closed, and have them taken charge of by the Company, and rendered perfectly secure against burglars by a telegraphic communication with the nearest District Call Station of the Company, where a policeman will always be in readiness day and night to respond to calls.

Provincial combinations to work under the Company's Patents will be treated liberally.

The Company is also prepared to supply Municipalities with its system of

STREET FIRE ALARMS

as recommended by H. M. Postal Telegraph Department to the Metropolitan Board of Works for the Metropolitan Fire Brigade, and which has received favourable mention by Captain Shaw in his last annual report.

These Alarms have recently been considerably improved by the Company, and are acknowledged to be the simplest yet constructed.

All communications to be addressed to the Secretary as above.

THE NEW MATERIAL

For ENGINEERS (Sanitary and Hydraulic), ELECTRICIANS, AXLE MAKERS, BRASSFOUNDERS, PUMP MAKERS, RAILWAY COMPANIES, CARRIAGE and WAGGON BUILDERS, &c.

SUBSTITUTE FOR LEATHER, RUBBER, AND PERCHA.

It is unequalled for Washers of all kinds, Hot and Cold Water Packings and Plumbers' uses generally, Insulators, &c.

THE PATENT VULCANISED FIBRE

Is supplied in Sheets from 1-32in. to 1in. in thickness, and in two qualities: Flexible, 2s. per lb.; Hard, 2s. 3d. per lb.

MOSSES & MITCHELL, 62, QUEEN VICTORIA STREET, LONDON.

TO SHIP OWNERS, SHIP BUILDERS, AND CAPTAINS.

No VESSEL should proceed to Sea without her boats being fitted with

"CARPENTERS" PATENT DETACHING AND PICKING UP GEAR.

Admitted by all to be the most simple, secure, and complete ever adopted.

It is under the control of one man, and quick and certain in action. Hooks are entirely dispensed with.

The Gear can be used by any person, however unaccustomed to ships' tackles and falls. A large number of vessels have been fitted, ncluding the Telegraph ships "CHILTERN," "JOHN PENDER," and "FARADAY."

For full particulars apply to Mr. WATSON SMITH, Managing Director,

BRITISH AND FOREIGN BOAT LOWERING APPARATUS COMPANY (Limited), 6, Great Winchester-street,

Or the Agents:—Messrs. SCRUTTON and CAMPBELL, 114, Fenchurch-street, London, E.C.; and Mr. ALFRED SIMEY, 3, Arcade Chambers, Sunderland.

WANTED, a thoroughly practical ELECTRICIAN, or ENGINEER well up in electricity, to undertake the management and development of an Electric Lighting Department with a Company who are in possession of certain patents for electric lamps. Address, by letter, 411, Oxford-street, W.

WANTED, VOLUME VII. of "THE ELECTRICIAN." Apply, by letter, stating price, to J. S. T., 2, Walton-street, S.W.

WANTED, a GENTLEMAN to CALL UPON ELECTRIC LIGHT MANUFACTURERS with SAMPLES of quite NEW INVENTIONS for insulating and other purposes connected with Electricity. A large business can be readily effected by a really first-class man, to whom liberal terms will be accorded. Address, "Lux," Office of "The Electrician," Strand, W.C.

ENGAGEMENT REQUIRED by an ELECTRICIAN for Electric Light Company. Has four years' practical experience in arc as well as incandescent lighting.—A. B., 20, Frith-street, Soho.

A QUANTITY of INSULATED WIRE, 7-22 Copper G.P. No. 1; also No. 14 Copper 11-32 G.P., considerably under cost.—H. R., 2, Harcombe-road, Stoke Newington.

ELECTRICIANS desiring FINANCIAL ASSISTANCE to develop and utilise their discoveries are invited to address E. D. C., care of C. MITCHELL and Co., Advertising Agents, Red Lion-court, Fleet-street, E.C.

LIFE ASSOCIATION of SCOTLAND.

Founded 1838.

HEALTHY PERSONS OF ALL AGES will find in the BONUS SYSTEMS of the LIFE ASSOCIATION of SCOTLAND advantages far exceeding those which can be obtained under any of the ordinary systems.

Claims and Bonuses paid.............................. £4,028,000
Annual Revenue 436,000

Immediate Entrants in Class A will secure ONE YEAR'S BONUS MORE THAN LATER ASSURERS in that class.

LONDON—5, Lombard-street, and 48, Pall Mall.

SLIP

Cable Interrupted.—The Great Northern Telegraph Company announce that their Amoy-Shanghai cable is interrupted.

Brazilian Submarine Telegraph Company. — The traffic receipts of this company for the five weeks ended May 26 amounted to £14,561.

Electric Light for Portsmouth.—It is stated that arrangements are being made for testing the electric light in some of the principal thoroughfares of this town.

Electric Light for Kensington.—The Kensington Vestry have appointed a sub-committee to consider the question of introducing the electric light into the parish.

Cable Repaired.—The Brazilian Submarine Telegraph Company's St. Vincent-Pernambuco cable, which was found to be interrupted towards the latter end of last week, has been repaired, thus restoring communication with South America.

Western Brazilian Cables Repaired.—The Western Brazilian Telegraph Company notify the repair of the Bahia-Rio de Janeiro section of their cables, and with this repair their whole system between Para and Montevideo is now in perfect working order.

The Swan Lamp.—We hear that the Swan Electric Light Company, of Newcastle-on-Tyne, have received an order to erect their lamps in Blagdon Hall, the seat of Sir M. W. Ridley, Bart., M.P. Blagdon Hall is situate, we believe, near Newcastle.

Electric Light at Bedford.—The Bedford Domestic, Artistic, and Scientific Exhibition, which opens on the 6th June, will be lighted with Brush arc lamps, for which a contract has been made with the Provincial (Brush) Electric Light and Power Company (Limited).

Electric Light in a Salt Mine.—The Witton Hall Salt Mine in Warrington-road, Northwich, is now lighted up by Brush lamps in place of the candles generally used. There are sixteen large arc lamps employed. The lights were erected by the Hammond Company, of Dale-street, Liverpool.

Cable Ship "G. E. Wood."—The India Rubber, Gutta Percha, and Telegraph Works Company have received a telegram from Mr. H. Benest from Galveston, announcing the safe arrival of the ss. "G. E. Wood" at that place on the 25th May. She will proceed at once to the laying of the cable she carries.

Underground Wires in New York.—The sub-committee appointed at Albany to report upon the practicability and feasibility of laying wires underground in cities in New York State have made a report in which they strongly urge the Legislature to pass a law compelling telegraph and telephone wires to be run underground.

South African Telegraphs.—The revenue receipts from the telegraphs in Cape Colony for the month ended March 31, 1882, were £5,686, against £5,402 in the same month of last year, or an increase of £284. For the quarters ended same date the figures were respectively as follow:—1882, £15,238, and 1881, £14,274, or an increase of £964.

The Worcestershire Exhibition.—The city sheriff of Worcester, Mr. Goodwin, having offered to place sufficient engine power at the disposal of the committee of this exhibition for electric lighting purposes without any further charge than engineman's wages, the hon secretary has been authorised to negotiate with the Hammond Company to supply the Brush light for four months, at a cost not exceeding £200.

Crystal Palace Electrical Exhibition.—We understand that it is probable that this Exhibition may remain open for a further period, the management having sent out circulars requesting the exhibitors to keep their stalls open for another three months. We believe that the replies to these circulars have in most cases been satisfactory, and that a good majority of the stands will remain open for the above period.

SS. "International."—The ss. "International," belonging to the India Rubber, Gutta Percha, &c., Works Company, arrived at Kingston, Jamaica, on the 25th May. She will coal there, and then proceed to complete the Galveston-Tampico section of the Mexican Telegraph Company's cables. Mr. Theophilus Smith joins the "International" at Kingston with Mr. J. Rymer Jones, and takes charge of the expedition.

International Electrical Exhibition at Vienna.—The General Committee of this Exhibition held a meeting on the 25th May, when it was proposed and carried that the Electrical Exhibition should be postponed until March or April, 1883. This alteration has been brought about owing to the Viennese manufacturers having promised to exhibit at Munich, Trieste, or Nuremburg before the date of the Vienna Exhibition was decided upon.

The Jablochkoff Light in Paris.—The Compagnie Générale d'Electricité announce that the Jablochkoff light has only been temporarily discontinued in the Avenue de L'Opera at Paris, owing to a re-arrangement of the works. The Municipality have renewed the company's contract for lighting the avenue for another three years, and have also given them power to introduce the light into the houses in the district served by their mains.

Edison Lamps in Brussels.—We are informed that the Edison incandescent lights, as fitted up in the restaurant and dining rooms of the Musee du Nord at Brussels, have proved entirely satisfactory, and fully meet the expectations of the management and public. It is now proposed to increase the plant to twice its present capacity, which consists of one dynamo and 120 lamps of one carcel intensity. Mr. E. G. Acheson is the engineer in charge of the work.

Tenders Wanted for Electric Lighting.—The Camberwell Vestry are inviting tenders for lighting a portion of their parish by electricity as an experiment. Further particulars, with specification, &c., can be obtained at the surveyor's office, Vestry Hall, Peckham-road, S.E. Tenders are to be sent in sealed, and endorsed "Tender for Electric Lighting," and delivered at the Vestry Hall by 5 p.m. on the 12th June, on which day the general purposes committee of the above vestry will meet to consider them.

Charing-cross Electric Railway.—The Charing-cross and Waterloo Electric Railway Bill, which passed unopposed through the House of Commons, has been stopped in its passage through the House of Lords, the examiners having reported that the standing order of the House applicable to this Bill has not been complied with. The Bill has, therefore, been referred to the Standing Orders Committee, which was to meet yesterday (Friday) the 2nd of June, for them to decide whether the Bill should be allowed to proceed.

The Hickley Telephone.—In the High Court of Justice on May 25, before Mr. Justice Fry, Mr. Cozens-Hardy, Q.C., with Mr. Moulton, applied on behalf of the United Telephone Company for an interim injunction to restrain Messrs. Orme, engineers, of 65, Barbican, from selling Hickley tele-

Digitized by Google

phone receivers—which were held by his lordship in the action against Messrs. Harrison, Cox-Walker, and Co. to infringe the patent the plaintiffs hold for Bell's telephone—until the hearing of the case of the United Telephone Company *v.* Orme and Co. The injunction was granted.

Magnetic Properties of Steel and Iron.—Mr. L. M. Cheesman sums up the result of his investigations into the effect produced by the mechanical hardening of iron and steel on their magnetic properties in a paper contributed to the *Annalen der Physik and Chemie* as follows:—"Iron in a mechanically hard condition can receive more permanent magnetism than in a soft condition. The magnetic moment of a steel magnet in a mechanically hard condition is greater than in a soft condition, according as the ratio of its diameter to its length is less or greater than a certain limit."

Private Electric Lighting Bills.—The Select Committee on Electric Lighting have resolved to recommend to the House that all the clauses asking for powers to supply electric light be struck out of all the private Bills this Session. The Committee have likewise come to several conclusions as to the regulations to be applied to the supply of electricity for lighting purposes, which they have drawn up in the shape of resolutions. They are given in another column. It is understood that these will be incorporated as amendments of the Government Bill. The Committee have adjourned until Thursday, June 8th.

Thunderstorm in Paris.—The Paris correspondent of the *Standard*, describing a heavy thunderstorm which occurred early on Monday morning in Paris and the neighbourhood, says:—"Houses in the Grande Rue de Passy and in the Rue de Boulainvilliers were struck by the lightning. Severe storms and heavy showers are reported from different parts of the country, particularly from Pontoise and Chatellerault. In the latter place the walls of several houses were destroyed by the lightning, and the cellars were inundated by the torrents of rain. For two hours the thunder never ceased, and 1,200 flashes of lightning were counted within that period."

Patents.—The Commissioners of Patents have just issued two volumes of abridgments relating to electricity. The first includes all the specifications having reference to electro deposition and electrolysis from the earliest period down to the end of the year 1876. A very liberal scope is given to the words, so as to include methods of protecting ships' sheathing where electricity is supposed to come into play, as well as a number of eccentric patents for purifying and extracting metals by the aid of voltaic currents. The other volume relates to the generation of electricity and magnetism, and deals with the patents from 1867 to 1876 inclusive, the earlier years being included in a volume issued some time back.

Electric Meters.—In *La Lumière Electrique* for the 27th May, M. Marcel Deprez contributes an article on these meters, in which he gives extracts from his writings on this subject. He charges both Mr. Vernon Boys and Messrs. Ayrton and Perry with having reproduced his ideas and utilised the information contained in his writings in the construction of their respective instruments for measuring electricity without having credited him with the invention. He also asserts that Mr. Boys has adopted the form of integrater invented by M. Abdank-Abakanowicz. In the present article M. Deprez describes his own instrument with illustrations, and reproduces the description of Mr. Boys's meter, as given in *The Electrician* of recent date; he also announces his intention of describing and illustrating the integrater of M. Abdank-Abakanowicz in a future article.

Telegraphic Communication between Reigate and Redhill.—In the House of Commons on Thursday week Mr. Freshfield asked the Postmaster-General if his attention had been directed to the very imperfect and unsatisfactory telegraphic arrangements between the towns of Reigate and Redhill in Surrey. Those places were less than two miles apart, and contained 8,000 and 10,000 inhabitants respectively; they used until lately to be united by a wire, but now all messages between them and the surrounding populous towns and villages had to make a circuit of fifty miles, and were subject to much delay and uncertainty, having to pass through a busy London office; and whether he would cause measures to be taken to remedy this evil.—Mr. Fawcett stated, in reply, that it had been decided to make certain improvements, under which Reigate would have communication with Redhill by a direct wire.

Society of Telegraph Engineers and of Electricians.—The council have determined that this society shall offer three premiums annually for the best original paper sent in to the society on telegraphic or electrical subjects during the session by any person not being a member of the council of the society. The first premium will be called the Society's Premium, and have a value of £10; the second, the Paris Electrical Exhibition Premium, value £5; and the third, the Fahie Premium, value £5. The awarding of the premiums will rest with the council, to whom power is reserved of declining to award either or any of the said premiums in any year in which they may consider the papers offered as unworthy of the distinction. The premiums will consist of books or scientific apparatus. No person will be entitled to receive more than one of the said premiums in any one year. The first premiums will be awarded in 1883 for the best papers sent in between this date and the end of May next.

Legal.—Seaver v. Philippart.—This was an action brought in the Chancery Division of the High Court of Justice on Friday, the 26th May, by Mr. F. I. Ricarde Seaver in order to obtain an injunction to restrain the Faure Electric Accumulator Company from issuing to M. Simon Philippart, or to a Belgian Company called La Force et la Lumière, any share in the Faure Company, and to restrain Philippart and the Belgian Company frrom dealing with any of such shares or taking the certificates for the same out of the jurisdiction, and in order to obtain payment of a commission of 5 per cent. upon the net profits in cash or in shares of the Belgian Company in launching the Faure Company, to which commission the plaintiff alleged himself to be entitled under an agreement made on April 6th, 1882, between himself and the Belgian Company.—Vice-Chancellor Hall made an order for an injunction in these terms extending over the first motion day in the next sittings, directing the plaintiff to give the usual undertaking as to damages, and giving the defendants leave to move on short notice to dissolve the injunction.

New Companies.—The following new companies have been started since our last issue, viz.:—The British Indian Electric Light and Power Company (Limited), with a capital of £250,000. It has been formed to work throughout India the patents and systems owned by the Electric Light and Power Generator Company, including the Weston, Rapieff, Lontin, and Maxim machines and lamps.—The Continental Electric Light and Power Corporation (Limited) has been formed to purchase Gülcher's patents for the supply of the electric light and power in France, Austria-Hungary, Belgium, and Germany. The capital is £400,000.—The Self-Generating Electric Light and Power Company (Limited) has a capital of £300,000, and is formed to acquire the in-

Digitized by Google

vention of Mr. R. H. Simons, for the production of electricity by a self-generating process, and also to work his incandescent lamp. The prospectus does not say how or by what means it accomplishes the "self-generating process," and justifies its title.—The Laing Electric Light and Power Company has a capital of £1,000,000, and has been formed to work Mr. Laing's system of arc lighting.

Overhead Telephone Wires.—The case of Twigg *v.* the British and Irish Telephone and Electric Works Company was heard recently before Mr. Justice Bowen. The action was brought to recover compensation for injuries arising from the fall of a chimney under the following circumstances:—The plaintiff, Mr. George Twigg, is a clipping machine manufacturer, at Birmingham, and alleged that he allowed the defendants to attach a wire to his chimney-stack, under an indemnity that they would pay for any damage which might result in consequence. On the 14th of October, 1881, during a heavy storm of wind, the wire gave way upon one side of the chimney, and subsequently the chimney-stack fell, and caused serious injury to the plaintiff's property. The plaintiff, therefore, claimed compensation. The defendants, on the other hand, alleged that the chimney was of such a weak construction that it would have fallen if the wire had not been attached, and that the wind was the sole cause of the accident.—The jury gave a verdict for the defendants upon the ground that the wire was not the cause of the chimney falling, and judgment was given accordingly.

A New Electric Lamp.—The *Operator* is responsible for the following:—"Mr. Henry Goebel gave an exhibition of his electric light, on the night of the 30th ult., in a room back of his store at 468, Grand-street, New York. Mr. Goebel claims that he has been at work on electric lights for thirty-one years, and that twenty-nine years ago he arranged one on the top of his house at 271½, Monroe-street. The light was seen from the Essex Market bell-tower and an alarm of fire was given, which brought out a number of engines. He himself was arrested, but Judge George Woods released him. When he returned home he found that his neighbours had demolished all his instruments and apparatus. The light exhibited recently was clear and steady, and one could read by it with great comfort and ease. It is about eight inches long and about as thick as a candle. The vacuum is obtained by a pump similar in principle to the Gessler pump, and can be operated by unskilled hands. The carbon points used are made of reeds, which are heated in the retort by electricity. The lamps cost 25 cents. apiece, and Mr. Goebel claims that he can furnish a light as cheap, if not cheaper, than gas."

Awards to Telegraph Messengers.—On Saturday last Mr. S. Walliker, Postmaster of the Birmingham Post Office, presented a certain number of the telegraph messengers with the certificates of merit earned by them during the last six months for celerity in the delivery of telegrams. This "merit system," as it is called, was inaugurated by the Postmaster six months ago, with the view of effecting the quickest possible delivery of telegrams. Under the system, the time of giving the message to the boy is entered, and a similar entry is made on his return (sufficient time being allowed for the various distances), and if the allotted time is exceeded, an explanation is called for. Every minute a boy loses is recorded, and the boy who loses the fewest wins the highest place. The places gained are exhibited weekly, and constant emulation is excited. "The results of the system," says the *Birmingham Daily Post*, "are shown by the facts that whilst during the first week, some eight months ago, the average delay per boy above the allotted time was seventeen minutes per day, the average delay for the entire week just ended was a little under five minutes for the week. One boy has worked thirteen weeks with a total loss of only two minutes."

The Patent Laws.—Mr. H. T. Wood, secretary to the Society of Arts, writes to *The Times* of 25th May, referring to the article on the present state of the patent laws, from which we gave a short extract in our last week's issue, and calling attention to the fact that the Society of Arts Patent Bill, now before the House of Commons, and which was read a second time a month ago, provides a remedy for some of the defects described in the article referred to. Mr. Wood says:—"It (the Bill) provides for an examination, not, indeed, into the merits or utility of an invention, but into the way in which the invention is described in the specification. It reduces the fees in the initial stages to a third of the existing amount; and it provides for the trial of patent cases by skilled Commissioners of Patents, acting as arbitrators, or by a Judge having these Commissioners sitting by him as assessors. Had our Bill been law last week, Edison's patent could not have been upset on the purely technical point that he had included in his provisional specification a certain invention which in his final specification he did not proceed with. Such a defect would have been discovered before the grant of the patent and set right; while even had it not been so set right, the defendant would have been expressly debarred from setting it up as his defence."

The Postmaster-General and the Telegraphists.—Mr. Macliver, M.P., has written a letter to the Postmaster-General, in which he says that his experience leads him to the conclusion that the retention of efficient telegraphists is a matter of great public importance. "It is to be feared," he thinks, "that if the dissatisfaction which continues to prevail among the best class of telegraphists be permitted to continue, the Post Office will ultimately lose the services of many highly-trained men, who might be retained without incurring any large expenditure. Among the 6,000 telegraph clerks in the United Kingdom there are from 600 to 700 pre-transfer men, whose claims to special consideration are worthy of careful examination. I believe that the utmost these pre-transfer men have asked for is to be placed on the same conditions as Post Office clerks. I have been requested to bring this matter before you, and I do so on public grounds, believing that the satisfaction of the claims of the pre-transfer telegraphists—who joined the Post Office under distinct promises—would prove advantageous to the public, and especially to all who have occasion in their business to make use of the telegraph to a large extent." To this Mr. Fawcett has replied that he has spared no pains to discriminate between the "legitimate and illegitimate claims of the telegraphists," and that although he knows that no arrangement can be devised which would satisfy everybody, he feels confident that the settlement of last year fully meets the justice of the case. He concludes, "Under these circumstances I cannot consent to re-open the question. I believe there is no ground for the fear you express that the department will lose the services of many of the best telegraphists, as in several instances telegraphists who have lately left have earnestly entreated to be permitted to re-enter the service."

The Telephone Case.—Mr. Hunning writes to *The Times* on the subject of his telephone as follows:—"The means I employ in the transmission of speech is the vibration of visible grains of the hardest and lightest oven-made engine coke, no dust or impalpable powder being mixed with them. If any compression in the shape of a 'tension-regulator,' as described in the Edison patent, is applied to my in-

Digitized by Google

vention, it becomes useless as a telephone transmitter. I cannot venture to trespass upon your space further, but conclude by saying that I verily believe my invention is a distinct invention from Edison's, and in no way can be called 'a tension-regulator.' If any tension is applied to my free grains of oven-made engine coke or to the free grains of any other good conductor, you prevent their free rubbing together, and come back to a worse transmitter than the Bell telephone." Mr. J. Munro writes:—"In the Rev. Dr. Hunning's letter the 'tension-regulator' of Edison's patent is spoken of as if the word 'tension' meant mechanical stress, whereas it has been held by the Court, and by the experts engaged, to mean intensity or strength of current. Tension is a discarded electrical term, once vaguely used to mean electromotive force, and sometimes, also, intensity of current. A tension-regulator thus becomes a strength of current regulator. This correction, however, leaves Mr. Hunning's position as good as before, for in the same sense a Reis transmitter and a microphone are 'tension-regulators.'" With regard to Edison's phonograph and the apparent clashing between the judgments of Lord Maclaren in the Edinburgh Court and the more recent one of Mr. Justice Fry, Mr. Munro points out that "Lord Maclaren had only to decide whether a single phrase in the provisional specification indicated the phonograph or not; whereas Mr. Justice Fry had to consider the far more fatal objection that a non-electrical instrument (the phonograph) was claimed in a patent for transmitting speech electrically, without any connection with the purpose of the patent having been expressed in the claim."

Experiments with the Electric Arc in Vacuo.—MM. Jamin and G. Maneuvrier communicated a note to a recent meeting of the French Academy of Sciences describing the following experiments with the electric arc in vacuo, the current being supplied by a Gramme dynamo machine:—"Having taken an egg-shaped glass tube and placed in it two carbons of ·15 metre length and 4 millimetres diameter, arranged point to point, and separated by an interval of 4 millimetres, when the vacuum had attained about 12 millimetres light began to break forth, not only in the form of a highly luminous arc between the carbon points, but from all parts of the carbons, and similar in appearance to that ordinarily seen in Geissler tubes. Each carbon was surrounded by a blue aureola, that of the positive carbon being the paler. The carbons subsequently became heated, reddened, and then got white hot, not only at their ends but throughout their length; they were then rapidly volatilised by the combined effect of the heating and the electrical currents. Whatever be the cause of this volatilisation it is certain that carbonaceous matter is given off in a vaporous state. The vessel or tube is filled with a blue gas somewhat similar to the vapour of iodide, which gradually deepens to the colour of indigo. After this the vapours are condensed on the sides of the vessel, which become opaque, and this ends the experiment. The deposit thus collected resembles finely-divided carbon, and dissolves with effervescence and incandescence in nitric (*azotique*) acid. Is it pure carbon, or is it a composition of hydrogen and carbon? This is a question which I reserve for further experiments. To avoid this summary termination of the experiment, I replaced the single carbons by two bundles of similar carbons. In this case the currents divided into a large number of flows, less intense than the single flow; all the carbons gave light at the same time, and heated the less the more numerous they were. There was hardly any volatilisation, and the effect was prolonged as long as one wished. I replaced the carbons by copper rods ·003 metre diameter. The same effect was produced with still greater success. If the current was too strong the copper melted. It always partly volatilised, and was deposited in a thin layer on the glass. It is plain that the experiment can be varied by using different metals, different gases, and by operating under different pressures."

Underground Wires.—In a letter to the Philadelphia *Times* of May 18, Mr. David Brooks deals with the question of underground wires, particularly referring to electric light conductors. It appears that a Bill is now before the council of the city, the object of which is to give permission to electric light companies to erect poles for their wires, and Mr. Brooks points out that the objections to overhead electric light wires are even stronger than to overhead telegraph or telephone wires. We make the following extracts from his letter:—"To compel the telegraph and telephone companies to place their wires under ground would put those companies to great expense. When such change is made it must be gradual. How much easier it will be for the electric light wires to be placed under ground in the first place than to make a change after they have an expensive plant of poles and overhead wires. Much is said of the Brush Company for having lighted Chestnut-street free of cost. So far as I can learn they have marred the appearance of the street by day more than their lights have improved it by night. Not in all the lanes and by-ways of the United Kingdom of Great Britain can be seen so ungainly, unsightly telegraph poles as are now seen from my front window on Chestnut-street. The Jablochkoff Company of Paris lighted the Avenue de l'Opera for a long time free of cost; they have far many more lights on that avenue than are now placed in Chestnut-street. The conductors were laid directly under the asphalte pavement near the curb, convenient to be attached to the conductors inside the lamp-post. No conducting wires are seen outside of the lamp-post. This makes it easy to have a lamp post of symmetrical proportion. The lamp-posts in Avenue de l'Opera are ornamental. Is there anything to admire in the form of these post on Chestnut-street as compared to the old gas lamp-posts? The Anglo-American Brush Company and the British Electric Light Company have each lighted portions of London free of cost. All their conductors were placed underground. The Thames Embankment, together with Waterloo and Westminster Bridges and the vicinity of Westminster are most beautifully lighted by the Jablockkoff and Brush lamps, and not a wire to be seen. Telegraph and telephone lines have become in a measure a necessity. The change from overhead to underground cannot be made without inconvenience to the public. In that respect electric lighting may be considered more like a luxury. They are not needed, or certainly not a necessity. The Edison Company, of New York, appear to have commenced right. They have now ten miles of pipe laid containing electrical conductors. The insulation is carefully tested from day to day, with quite satisfactory results. All of the systems now in use in Europe are available for companies in this country, and nothing but an inordinate desire to make quick fortunes prevents their use. One of these companies state they have twenty millions of dollars to carry on this work. I should judge they saw twenty millions before them within easy grasp provided this Bill should pass. One councilman stated that the town of Albany, with forty thousand inhabitants, had more electric lights than Philadelphia. He should have added that the citizens of Albany are praying the Legislature for relief from poles and conductors."

THEORY OF MAGNETO AND DYNAMO MACHINES.

XIV.

We have now proved conclusively, what is abundantly confirmed by experiment, that currents are induced in every conductor moving in a magnetic field in such a way that the number of lines of force passing through it varies; and that the electromotive force urging these currents is precisely equal to the rate of change in the number of these lines of force, or the number added or subtracted every second from the area enclosed by the conductor.

So to generate currents in a brass curtain ring it is only necessary to spin it on the table. There are reverse currents at every half revolution, and their strength was investigated last week. Currents flow round a finger ring every time the wearer moves his hand. Let us take a numerical example to show that, though the E.M.F. produced by the feeble magnetic field of the earth is but slight, yet in a massive conductor of low resistance the currents produced are not insignificant.

Take a ring of copper 8 inches or 20 centimetres in mean diameter, and with a cross section of half a square inch or 3 square centimetres (weighing, therefore, a little over 3 lbs.), and spin it about a horizontal east and west axis n times a second. It will cut all the earth's lines of force which pass through it four times in every revolution, for they are taken out in two of the quadrants and put in in the other two.

The total intensity of the earth field is ·46, or ·46 lines of force pass through every square centimetre normal to the dip; hence the total number passing through the ring is $\cdot 46\,\pi\,r^2 = 46\,\pi$. In every revolution all these lines are cut four times, and it makes n revolutions in a second; hence the average E.M.F. acting is $184\,\pi\,n$.

The current depends upon this and the resistance. Now the resistance of the ring is the circumference divided by the sectional area, viz., $\frac{20\,\pi}{3}$, multiplied by the specific resistance of copper, viz., 1710; so it comes out $11400\,\pi$ centimetres per second. The average current during the rotation is, therefore, $\frac{184 n}{11400}$ C.-G.-S. units.

Let us put these into practical units, on the supposition that the ring makes 1200 turns a minute—that is, if $n = 20$.

The E.M.F. is only ·000115 of a volt; but, as the resistance is but ·0000354 of an ohm, the current is 3·28 amperes.

The power that must be expended to drive the ring against the electrical forces, over and above friction, is $E\gamma = \gamma^2 R = \frac{E^2}{R}$ (whichever expression is preferred), viz., $\frac{(184 n)^2 \pi}{11400}$, or 3712 ergs per second, which is only half-a-millionth of a horse-power. The heat generated per second in the ring will be ·0000888 of a thermal unit, so it would have to spin for ten hours before enough heat was generated to raise 3 grammes of water 1 degree Centigrade; and the rise of temperature of the ring would only be a degree in three weeks, even if there were no cooling.

But then remember that the ring is spinning, as many things spin, simply in the ordinary space near the earth, in the exceedingly weak magnetic field of intensity ·46. But if it were spun between the poles of a magnet, the field in which it was might easily have the strength 460, or perhaps even 4600, and then we should have a very different state of things.

Thus, to take the more moderate case, let the field in which the ring is spinning 1200 times a minute be 1000 times as strong as the earth's; that is, let it have 460 lines to the square centimetre. The average strength of the induced current would then be 3270 amperes, the power required to turn the ring would be half a horse-power, and the heat generated 88·8 thermal units per second. The temperature of the copper ring (whose thermal capacity about equals 150 grammes of water) would, therefore, rise more than half a degree every second at first, *i.e.*, until it got distinctly hotter than the atmosphere. In about a minute it would probably have run up about 20 degrees, and it would not cease to rise until it got so much hotter than the air that it was able to pour out 90 heat units every second, or 16 units a minute from every square centimetre of its surface.

We have taken a ring as being very easy to apply arithmetic to, but there is no reason to take a perforated figure. A disc or a sphere would do as well, only it is not so easy to say what their effective resistance would be. But it is important to observe that a moving conductor acts in precisely the same way whether it is bounded by a non-conductor or not. In other words, a portion of a great mass of copper bounded by flow lines may be treated as if detached and surrounded only by air. A steadily spinning sphere is cutting lines of force just as effectively as a loop or ring.

Suppose, now, that instead of a massive ring we spin a coil of wire of the same size and weight, the size and weight of the insulating material being for the present left out of account; and suppose the coil to consist of N turns of wire, and to have its ends joined. The effective area, and, therefore, the E.M.F. generated, would be N times as great as before; the resistance would be N^2 times as great; and the current would be $\frac{1}{N}$th. But the power necessary to turn it in the magnetic field, and the heat generated, would be *precisely the same* as if the ring were solid—or as if the coils were detached parallel ones instead of a continuous spiral.

It may be as well at this point to put the matter into symbols for convenience of future reference. Let the ring contain a mass M of copper wire of specific resistance r, and density ρ; let D be the mean diameter of the ring, and let N be the number of turns of its wire; then, no matter what the thickness or weight of the insulating material between the turns of wire, it will be always very nearly true that the electrical resistance of the coil is

$$R = \frac{N^2 \pi^2 D^2 \rho r}{M};$$

and that, if the coil is spun, n times round a second, in a magnetic field of intensity I, the average numerical value of the induced electromotive force is

$$E = N I n \pi D^2,$$

and that the average strength of current (still paying no attention to sign) is

$$\gamma = \frac{n I M}{N \pi \rho r}.$$

The only approximation here made is that we have neglected the sluggishness or inertia of the electricity due to what is called *self*-induction; but this becomes important when the speed is excessive.

The power required to drive the ring against the magnetic forces is

$$\frac{I^2 n^2 M D^2}{\rho r},$$

and the heat generated per second is, of course, this same quantity divided by J.

We will next determine the E.M.F. developed when the contrivances of Arts. IV. and VIII. are rotated by hand. But it is very easy—it is merely finding $\frac{dN}{dt}$ for them. In the present article we have not troubled about the value of this quotient for the spinning ring in its different positions; we have simply taken its average value. Its actual value at any instant depends upon sin θ, being $I A \epsilon \sin \theta$, and is of no particular interest; but for the spinning machines of Art. VIII. its actual and average values coincide.

THE MAGAZINES.—Mr. W. H. Preece, F.R.S., continues his article on "The Age of Electricity" in *Time* for June. The present article deals with telegraphy.

A CUPROUS CHLORIDE CELL.

BY A. P. LAURIE.

The cuprous chloride cell is a development from some experiments made on an iodine cell. The iodine cell consisted of a zinc plate and a carbon plate, immersed in a solution of iodine in iodide of zinc. A description of this cell was communicated by me to the Royal Society of Edinburgh about twelve months ago. Though it is a one fluid cell it does not suffer from polarisation, and consequently has a constant E.M.F.

There is a certain amount of local action in the cell, the zinc plate being dissolved in the iodine, and the zinc plate should, therefore, be removed from the cell when it is not being used.

This cell is evidently capable of being used as a secondary cell. On passing an electric current through it the iodide of zinc is decomposed, iodine being set free at the carbon plate, and zinc being deposited on the zinc plate.

It is not available as a secondary cell for practical purposes, as the closeness of the plates necessary in a powerful battery necessitates the use of a strong iodine solution, which acts very rapidly on the porous zinc deposit.

It is evidently necessary to attach the iodine to the carbon pole in an insoluble form, and, in searching about for some suitable compound of iodine, I devised the cuprous chloride cell.

This cell, like the last, may be used either as a primary or a secondary cell.

An uncharged cell consists of two copper plates immersed in a solution of chloride of zinc. On passing an electric current through the cell zinc is deposited on the one copper plate and chlorine separated at the other copper plate. The chlorine never appears as gas, it combines with the copper to form cuprous chloride, an insoluble white precipitate. The cell is now charged.

On connecting the two copper plates an electric current will flow from the one to the other until all the zinc deposit is reconverted into chloride of zinc, and the cuprous chloride is reduced to metallic copper. The cuprous chloride is held against the copper plate, and prevented from diffusing through the liquid to the zinc deposit by wrapping the copper plate in parchment paper. The E.M.F. of this cell is low, being ·75 volt, a Daniell being taken as 1 volt.

This is compensated for by its low internal resistance. While being charged no chlorine is given off. When the copper plate is completely coated with cuprous chloride the internal resistance of the cell rapidly increases. On now using the cell to supply a current it immediately returns to its normal low resistance. It will give out electricity but not take it in.

In a cell like the Faure, where the peroxide formed is a conductor, the cell indicates that it is completely charged by the copious evolution of gas. In the cuprous chloride cell, where the compound formed is a non conductor, no gas is given off, but the internal resistance increases. It is, therefore, necessary in the cuprous chloride cell, as in other secondary cells, to have a large surface at the negative pole. I find that I can prepare the best surface by the reduction of cuprous chloride paste. The copper plate, covered with a paste of cuprous chloride, and wrapped in parchment paper, is immersed in the chloride of zinc solution, along with a zinc plate. When the two plates are connected, an electric current flows from the one to the other, rapidly reducing the cuprous chloride to spongy copper. I sometimes cover the spongy copper with copper gauze in *metallic* connection with the copper plate, by solder, or otherwise. The copper gauze holds the spongy copper in position, and also makes a second surface of action for the chlorine.

The deposited copper is thus attacked by the chlorine both from the gauze inwards and the plate outwards. It is also useful in regulating the internal resistance of the cell.

I have used both upright plates and shallow copper trays, one inside another. The copper trays are the simplest possible form of cell, but present certain practical difficulties which I have not as yet surmounted. When used as a primary, this cell is very similar in principle to De La Rue's chloride of silver battery.

As a primary it has these two important qualifications :—

1st. There is no polarisation, and the E.M.F. is, therefore, constant.

2nd. There is no loss from diffusion of one liquid into another, as there is no second liquid to diffuse.

If in using it as a primary certain precautions were taken to prevent the oxidation of the cuprous chloride (it can be kept for months under water without any signs of oxidation), it should be a very durable and constant cell. I have not as yet tested its durability in this respect, but will do so very shortly.

THE TELEPHONE CASE.

The judgment of Mr. Justice Fry, as given in our last issue, was based upon the evidence given during the trial, evidence which we shall not attempt to reproduce *verbatim*, but merely abstract, giving what appears to be its main features.

Sir FREDERICK JOSEPH BRAMWELL said that for some years he had taken a scientific interest in telephony, and that as far as he knew before 1876 there was no instrument capable of transmitting articulate speech. He explained the action of the Bell telephone, both with electro and with permanent magnets, practically thus :—That the motion of the transmitting diaphragm creates a disturbance in the transmitting magnet field, and thus a current is induced in the coil; this current traverses the closed circuit, and hence the coil at the receiving end, when it acts on the magnet at the receiving end, disturbing its magnetic field, and producing a motion of the diaphragm there similar to the motion produced by the disturbing causes in the first instance. It was made clear in this part of the case that the charge against the defendants was "selling the Edison transmitter and the Bell receiver." Fig. 1 shows the ordinary Bell telephone :—

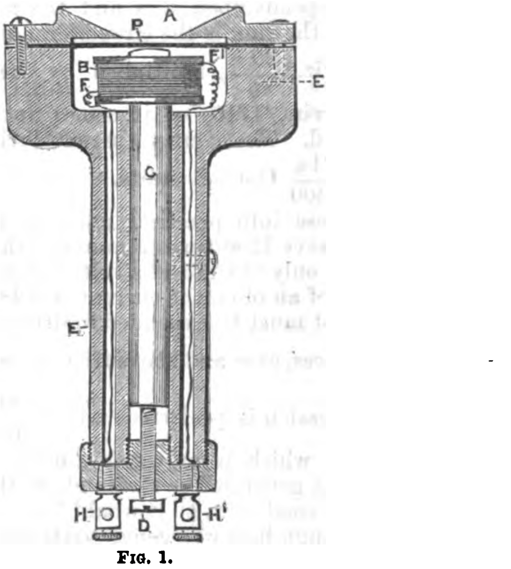

FIG. 1.

A permanent magnet, C, has a coil of wire, B, put round one end. In front of the magnet is a thin disc of iron P. When the iron is spoken to it vibrates freely to and from the magnet, but it affects the magnet by induction, altering the shape of the magnetic field, and so causing magnetic currents to cross the coils of insulated wire. The result is that electric currents are induced in the coil. These react on the magnet at the other end of the circuit through the wires F F', which connect to line wires through the terminals H H'. D is a regulating screw, A mouth-piece, E case. This is Bell's telephone, which requires no battery.

Various modifications have been suggested to increase the volume of sound obtained by using Bell's instrument as a transmitter, such as multiple magnets, large diaphragms, &c. The following extract from Bell's—Morgan-Brown's—specification, No. 4765, 1876, will make the points raised in this trial clear :—

"This invention relates to the reproduction by the necessary receiving instruments of any particular sounds or combinations of sounds through the agency of an electric current, whereby a multiplicity of telegraphic messages may be sent simultaneously over a single circuit in the same or in opposite directions, and received without confusion, and whereby articulate speech may be electrically transmitted. The invention relates to the production or

Digitized by Google

transmission of musical notes by means of undulatory currents of electricity, one battery being used for the whole circuit, whereby two or more telegraphic signals or messages can be transmitted simultaneously over a single circuit in the same or in opposite directions. The invention also relates to the electrical production or transmission of sounds of every kind by means of undulatory currents of electricity, whereby not only musical sounds but articulate speech can be transmitted over a telegraph line, and two or more messages be simultaneously sent over a single circuit in the same or in opposite directions. The invention also relates to the electrical production or transmission of sounds of every kind without a battery by means of undulatory currents of electricity, whereby not only musical notes but articulate speech can be transmitted over a telegraph line, and two or more messages be sent simultaneously over a single circuit in the same or in opposite directions. The invention also relates to the automatic reception of signals or messages by introducing at the receiving end of the line a local circuit containing a vibratory circuit breaker, whereby telephonic signals or messages may be automatically recorded. The invention

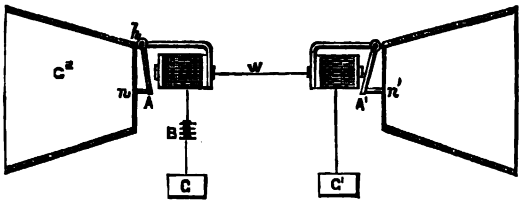

FIG. 2.

tion also relates to the application of electric telephony to autographic telegraphy, whereby characters or marks of any description may be copied in *fac-simile* at the receiving end of the line. In the first three plans described in this specification a separate instrument is employed for every pitch, and the electric vibrations for different pitches are combined upon the wire, each armature being capable of transmitting or receiving but a single note, and thus as many separate instruments are required as there are messages or musical notes to transmit. In the fourth part of the invention a single instrument is employed, the armature of which can be set in vibration by a musical instrument or by the tones of a human voice, or by any sound whatever. The telephones are illustrated in Figs. 2 and 3. One of the ways in which the armature may be set in vibration has been stated to be by wind. Another mode is shown in Fig. 2, whereby motion can be imparted to the armature by the human voice, or by means of a musical instrument, or by sounds of any kind. The armature A is fastened loosely by one extremity to the uncovered leg, *h*, of the electro-magnet E, Fig. 3, and its other extremity is attached to the centre of a stretched membrane, *n*. A cone, C², is used to converge sound vibrations upon the membrane. When a musical note is made in the neighbourhood of the membrane *n* it is set in vibration, the armature

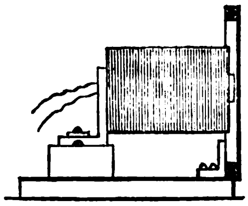

FIG. 3.

A is forced to partake of the motion, and thus electrical undulations are created upon the circuit G, B, E, W, E¹, G¹. The armature A¹ is thus thrown into synchronous vibration with the armature A, emitting a musical note of similar pitch to that which originated the vibration of armature A. If two or more musical notes be simultaneously sounded in the neighbourhood of the cone C², the resultant motion of the air is copied by the membrane *n* to which the armature A is attached, and this armature A, acting inductively upon the current traversing the coils of the electro-magnet E, occasions an increase and diminution in its intensity, and the armature A¹ is thrown into vibration by the varying attraction of the electro-magnet E¹ to which it is attached, and thus imparts to the air at n^1 a *fac simile* copy of the motion of the air that acted upon the membrane *n*. Hence two or more musical notes or telegraphic messages can be sent simultaneously along a single circuit from one station to another by means of one instrument at each station. Instead of the cone membrane and armature shown in Fig. 2, a plate of thin steel may be used; the vibrations of the plate in front of the magnet occasioned by the motion of the air during the production of sound changes the intensity of the current, and occasions a similar motion in a similar steel plate in front of another electro-magnet at another station in the circuit. Such a plate is shown in Fig. 3, it being attached to a frame. This invention is not limited, however, to the use of a steel plate, but includes within its scope any material capable of inductive action upon a current of electricity. In the telephone shown in Fig. 4 the magnet may be of the horseshoe form as shown at 24, and the coils of insulated wire 25 may surround soft iron cores or pole pieces, 26, screwed, or otherwise fastened to the ends of the magnet 24. The cores or pole pieces are placed near the face of the metallic plate A³, it being attached to a cup-shaped block, 28, having a central orifice, 29, for the reception of a speaking or hearing tube to convey sounds to or from the plate A³. The magnet is attached to a stud, 30, adapted to be moved in suitable grooves in the base 31 by means of a screw, 32, having its end connected with the stand, the body of the screw being fitted to turn in a screw-threaded stud. The movements of the

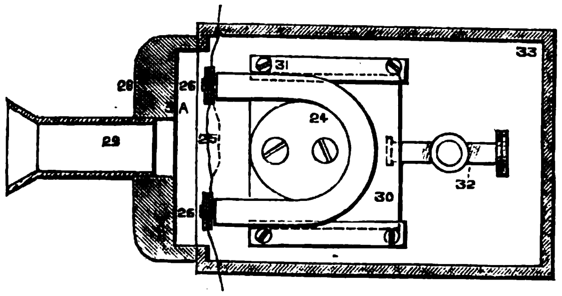

FIG. 4.

screw are just the distance between the pole of the magnet and the plate A³, and permit the poles to be placed almost in contact with the plate. The coils may be placed about the ends of the magnet 24, and the soft iron pole pieces be omitted. The coils will preferably be very thin, and be placed at the extremity or extremities of the magnet. One, two, or more magnetic poles with coils may be placed near a plate to intensify the effect. The soft iron core and coil may be attached to the plate instead of the magnet, or the core may be placed upon the plate, and the coil on the magnet, or *vice versâ*. The magnet may be made to vibrate instead of the plate."

The instrument of Bell giving such faint sounds when used as a transmitter great efforts were made to supersede it. And

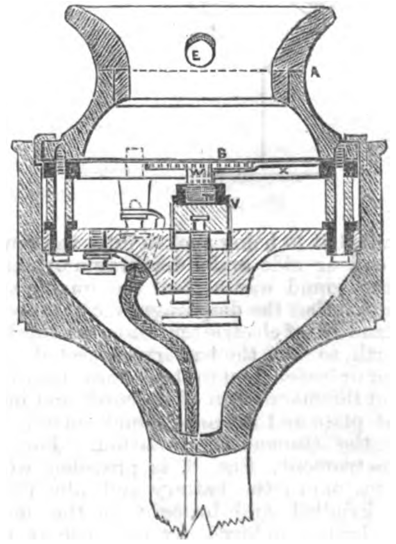

FIG. 5.

eventually different transmitters were used in conjunction with Bell's instrument as a receiver. One of these connected more especially with this case is Edison's transmitter. The action of this was described as follows:—"There being a battery to produce a current which is to go along the line wire to the receiving instrument there is at the transmitting end put in the circuit one of these tension devices of Edison. The tension device is made of something of semi-conductivity, lamp-black, plumbago, or of materials of an elastic character, which can be brought nearer together and will re-assert themselves when that which brought them nearer together is removed, and a tympan or diaphragm which need not be capable of inductive action—it may be of mica, for example—is caused to vibrate by the sound waves produced by the speaker, and in its vibration varies the

Digitized by Google

pressure on the tension device, thereby possesses more or less resistance to the passage of the current, and in this way changes the force of the magnet, electro-magnet, or permanent magnet at the receiving end, so as to cause the plate there, which is capable of inductive action, to make similar vibrations to the plate, or diaphragm, at the transmitting end, that is to say that, unlike the Bell transmitter, where the voice of the speaker always had to generate what I will call the operative electricity, which in the first plan of Fig. 5 was the only electricity, in Edison the voice of the speaker has merely to modify electricity which is provided by the battery." It will be best now to refer to Edison's patent. His claims have reduced the claims to a mica diaphragm, the electric tension regulator, and the phonograph. The tension regulator is in the shape of a carbon button, or lozenge.

The following extract from Edison's patent, No. 2909, 1877, will make matters clear:—"This invention relates to that class of electrical instruments in which sound becomes one of the elements in the transmission of the communication, and the same sound is produced at the receiving station, so that oral communications can be sent by electricity and clearly distinguished at the receiving station. In my present invention I make use of the vibrations given to a diaphragm or tympan, by speaking into a resonant case, to produce a rise and fall of electrical tension upon the line with such accuracy that the electric pulsations or waves will represent the atmospheric sound waves produced by articulation, and the electro-magnet at the receiving station will respond to the electric waves in such a manner as to reproduce the articulation by acting upon a resonant plate. The instrument in a complete form is represented in Fig. 5, being a section of the transmitting instrument. The resonant tube or box A is of a

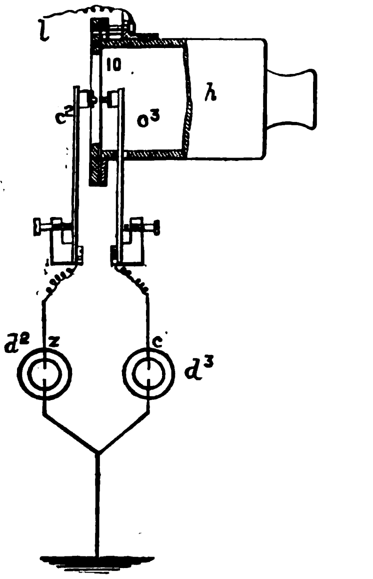

Fig. 6.

size and shape adapted to being spoken into, the same having an opening at one end or side and a diaphragm or diaphragms, B, against which the sound waves from the human voice act, and these and the motion that the diaphragm receives are the means of producing a rise and fall of electric tension on the line by the devices hereafter set forth, so that the battery connected to the line will transmit a greater or less current to the distant electro-magnet, and increase or lessen the magnetism of the cores, and in so doing act upon a resonant plate and develop sound corresponding to the articulation at the transmitting station. For convenience the speaking instrument, Fig. 6, is provided with a handle and flexible conductors to the battery and line respectively, so that it may be handled and brought to the mouth. Many materials have been employed by me, such as metals, horn, vellum, celluloid, ivory, &c., but almost all of these produce a prolonged or secondary vibration from their own resonant character. Hence the articulation is defective, and the sound vibrations blend. After extensive experiments I find that mica is almost entirely free from any resonant action, and hence it will respond with the greatest accuracy to the sound vibrations, and being of a laminated character can be employed of any desired thickness, and when secured at its edges responds with the greatest accuracy to the sound vibrations, and does not require to be strained; furthermore, the changes of temperature and atmospheric condition have little or no effect upon the mica diaphragm or tympan. I find that it is not practical to open and close the line circuits in instruments for transmitting the human voice; the circuit to the line must be always closed, and the transmission be produced by a rise and fall of electric tension, resulting from more or less resistance in the line. This resistance may be produced in several ways. I have shown several which will hereafter be named, but I find the most delicate to be small bunches or tufts, or discs of semi-conducting elastic fibre, such as particles of silk, and an intermediate conducting or semi-conducting material. This device I call an electric tension regulator; it is more or less compressed, according to the vibrations of the diaphragm or tympan, and the electric current rises in tension as it is compressed or lessens as the fibre expands. This fibre is placed in a small roll between a delicate diaphragm spring, and a variable presser, adjustible by screw or otherwise in the electric circuit at this point, or it may be within a cavity in said presser V, as in Fig. 6, there being a delicate cork centre piece, W, to the diaphragm B, with a piece of platina foil, X, in contact with the fibre. In all instances the telegraphic circuit at the diaphragm is made by a thin strip of platina or similar material extending to the centre from the line or battery connection. The fibre is rendered semi-conductive by being rubbed with plumbago, soft metal, or similar material, or by a deposit of metal upon its surface, or by fine particles of conducting or semi-conducting material mixed with it, the conducting power varying with the density of the tuft or bunch of fibre. I sometimes arrange the battery in connection with the transmitting instrument, as shown in Fig. 6. *h* is the resonant chamber, at the end of which is the diaphragm 10, and at each side of this diaphragm there are springs, c^2 c^3, having points made of compressed plumbago mixed preferably with gum rubber, but any substance not liable to rapid decomposition, or the elastic or fibrous tension regulator aforesaid may be used. These points face each other on opposite sides of the diaphragm, and make contact with platina foil discs secured to the diaphragm. The spring c^2 passes through a hole or small slot in the side of the chamber *h*. d^2 d^3 are the main batteries. The battery d^2 has zinc to the line or spring c^5, and the battery d^3 has copper to the line or spring c^3.

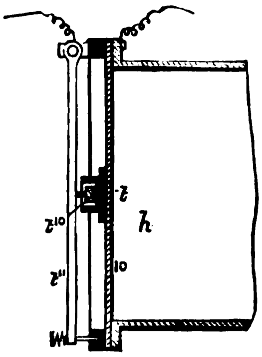

Fig. 7.

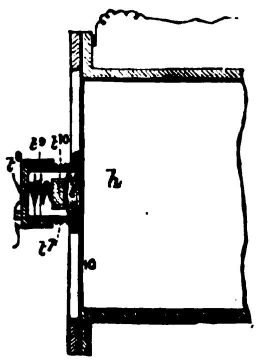

Fig. 8.

When the springs c^2 and c^3 are adjusted to make contact with the diaphragm equally, no current passes to the line; but when the diaphragm is vibrated its movement to one side, say c^2, causes a greater pressure upon the plumbago on that spring, and a lessening of the pressure on the plumbago on c^3; hence the balance of the batteries c^2 and c^3 will be destroyed, c^2, having the advantage, will send a negative current to line; upon the return of the diaphragm the battery currents will again neutralise each other. The vibration of the diaphragm to the other side causes the pressure to be reversed, and the battery d^3 will send a positive current to the line. As the tension regulator of fibre or of plumbago decreases and increases its resistance enormously under slight changes of pressure, it follows that the strength of the electric waves will be in proportion as the speaker's voice is strong or weak. For repeating from one circuit into another I use with the receiving diaphragm the elastic tension regulator Fig. 5 in addition to the electro-magnet, and connect the relay or second circuit through the same, so that waves received from the distant station cause the magnet to vibrate the diaphragm, and this acting upon the tension regulator transmits the waves into the second circuit, and they are received at the other end by an electro-magnet and diaphragm. By placing the fibrous tension regulator within a small band of india rubber the same is rendered more elastic, and the fibre is allowed to expand by the heat of the current without altering the electric tension. In cases where a strip of hard rubber or a cord of silk or other material coated with plumbago or metallic foil is introduced between the diaphragm and a rigid support, the expansion and contraction due to the passage of the electric currents will produce a movement upon the diaphragm corresponding to the diaphragm producing the electric pulsations. In some instances the diaphragm should be free to vibrate without being checked by contact with any stationary substance. I provide for this by placing upon the diaphragm or tympan 10, Fig. 7, a small cylinder l^7 of hard rubber or non-conducting material, within which is the

Digitized by Google

fibrous tension regulator t resting upon a piece of platina foil connected to one pole of the battery, and within this cylinder t^7 is a disc t^{10} of iron or other metal, loose, but pressed towards the tension regulator by a spring t^8 and screw cap t^9, and the other electric conductor is connected with said spring. The inertia of the metal disc causes more or less compression of the tension regulator as the diaphragm is vibrated, and hence the electric pulsations are sent over the line in harmony with the vibrations. Nearly the same effect is produced by connecting the disc t^{10} to a yielding spring that extends across from one edge of the diaphragm to the other, as seen in Fig. 8. This construction of tension-regulating device is especially available with large diaphragms. In some cases I use a soft rubber diaphragm immediately in contact with the transmitting or receiving diaphragm, so as to check or dampen any prolonged or false vibration, and render the sound more clear and free from prolonged tones. In preparing the tension regulator I find in some cases that it is preferable to use lamp-black mixed with pure plumbago, amorphous phosphorus, and a very small amount of non-conducting material, such as rubber dissolved in a solvent that will entirely evaporate."

The difference between Bell's and Edison's plan of modifying the independent line current when both used electro magnets was stated to be that in one case you modify it by a current generated by the voice, in the other by increasing or diminishing the resistance of a portion of physical substance through which the current passes. Reis's work was thoroughly discussed, but so far as this case is concerned the evidence seemed to point out that its action is by an intermittent current, whereas Bell and Edison claim action by an undulatory current.

(TO BE CONTINUED.)

THE SUITABILITY OF DIFFERENT MATERIALS FOR TELEGRAPH AND TELEPHONE WIRES.

BY MESSRS. FELTEN AND GUILLEAUME.

1.—*Telegraph Wires.*

The stipulations as to the conductivity of telegraph wires, until now only made by English telegraph engineers, having been introduced in the specifications of other telegraph administrations, it becomes the task of every telegraph wire manufacturer to test his wire as to its conductivity.

A great number of tests made with the different materials considered suitable for telegraph and telephone wires produced on an average the results collected in Table I., which will be of general interest.

These results give rise to the following reflections :—

Copper.—The use of copper for conducting wires was discontinued as soon as the application of telegraphs began to assume large proportions. However much copper may be recommended on account of its high conductivity, it appears to be the least suitable material for telegraph lines of any considerable importance, in consequence of its low-breaking strain and elasticity, as well as its high value, which render the investment so very great, besides exposing the wires to the danger of being stolen. The fact of copper being allotted a place in these tests is that it may serve as a basis for drawing a comparison between the qualities discovered in other materials.

Puddled Iron (generally called best best).—Iron has undoubtedly found by far the most extensive application for conducting purposes, and of the different kinds of iron, more especially puddled iron, which, with cheapness of cost, combines a sufficiency of conducting power. Formerly, it was usual to protect the wire from corrosion by means of dipping it in boiled linseed oil, until a means was found in the galvanising process which, though more expensive, proved far more efficient in affording the iron lasting protection from destructive atmospherical agencies.

The tests made with this material proved that in order to have a like conductivity resistance to that of copper wire the iron wire must have a sectional area $8\frac{3}{4}$ times as large as the copper wire. The specific gravity of iron in proportion to that of copper is as 6:7, therefore a wire of puddled iron will weigh $8\frac{3}{4} \times \frac{6}{7} = 7\frac{1}{2}$ times as much as a copper wire of equal conductivity. The strain brought to bear on the stays would be $7\frac{1}{2}$ times as much as in the case of copper wire of equal conductivity in consequence, but by virtue of its higher breaking strain, which is to that of copper as $40:28 = 10:7$, it is possible to span proportionately longer distances, *i.e.*, to place the stays farther apart.

With a view to a comparison of cost, the nominal value of a galvanised puddled iron wire of four millimetres may be taken as m.25 per 100 kilogrammes. The conductivity resistance of this wire is, according to measurements, 12 Siemens units per kilometre, *i.e.*, equal to the resistances of a copper wire of 1·4mm. A kilometre of galvanised puddled iron wire 4mm. thick weighs in round figures 100 kilos., costing m. 25; and as a kilometre of copper wire 1·4mm. weighs in round figures 14 kilos., and costs on an average m. 190 per 100 kilos. = m. 26·40 per kilometre, the difference in prices would not be great with equal conductivity.

Swedish Charcoal Iron Wire.—Of the different iron and steel wires Swedish charcoal iron wire possesses the highest conductivity, viz., $16\frac{1}{2}$ per cent. of that of copper wire.

With equal conductivity, a wire of that material may, therefore, be taken lighter in proportion, as $12 : 16\frac{1}{2}$ (or $8 : 11$) than a puddled iron wire. In such cases, where a puddled iron wire of 4mm. would be required, weighing in round figures 100 kilos. per kilometre, a Swedish charcoal iron wire of 3·4mm., weighing but 70 kilos. per kilometre, would be quite sufficient so far as conductivity was concerned.

By means of this material it is possible to considerably lessen the strain on the stays (by more than $\frac{1}{4}$th), and to construct the whole line lighter.

If, however, the Swedish wire is used in the same size as the puddled wire generally used, a greater rapidity of transmission is the result, as $11 : 8$.

The virtue of spanning, however, is less by 10 per cent (at least with the soft quality used for conducting wire) than that of puddled iron wire (the breaking strain amounting to only 36 instead of 40 kilos. per square millimetres) which necessitates a proportionate reduction of the distance between the poles.

It is true the Swedish material is considerably higher in value. A wire 4 mm. thick made of this material has a nominal value of m.45 per 100 kilos., being m.20, or 80 per cent. more than that of puddled iron wire. Taking into consideration the higher conductivity a wire of 3·4mm., costing about m.47 per 100 kilos. = m 32·90 per kilometre would but do the same service as a puddled iron wire of 4 mm. costing only m. 25 per kilometre. Swedish iron wire would, therefore, be 31·6 per cent. dearer than puddled iron wire.

It is to be concluded from this comparison that the Swedish material can only be chosen in such cases where the rapidity of transmission attainable, or the possible lighter construction of the line, will justify the greater outlay.

Swedish Bessemer Steel Wire.—With about the same conductivity as Swedish iron wire (16 per cent. of that of copper wire) the Swedish steel wire, in the temper solely suitable for conducting purposes, possesses the same breaking strain as puddled iron wire (40 kilos. per square millimetre of sectional area).

With regard to elasticity, the Sweedish steel and iron wire are not different from soft puddled iron wire, the changes of temperature having the same elongating effect on the one as on the other.

There is no difference in price between Swedish steel and iron wire. The only advantage of Swedish steel wire is, therefore, its higher breaking strain, whereas its conductivity is slightly less than that of iron wire.

German Charcoal Iron Wire.—This wire is about a medium between puddled iron wire and Swedish steel wire with regard to conductivity. It is only suitable for conducting purposes if quite soft, when it has the same breaking strain as puddled iron wire, viz., 40 kilos per □ mm.

As concerns elasticity it stands on a par with other soft iron and steel qualities.

For a comparison of prices the nominal value of German charcoal iron wire 4 mm. thick may be regarded as m.30 per 100 kilos, that is to say 20 per cent. higher than puddled iron wire of equal sizes.

Taking into account the superior conductivity of this quality, a German charcoal iron wire 3·7 mm. thick, will not afford a higher resistance than a puddled iron wire of 4 mm., at the same time weighing in round figures only 84 kilos. per kilometre and costing (at m.31·50 per 100 kilos.) m.26·46.

The cost would not exceed that of puddled iron wire of equal conductivity by more than 6 per cent.

The greater outlay would, therefore, as is the case with the Swedish material, only be justifiable by the necessity of a greater rapidity of transmission, or of a lighter construction at an equal speed of transmission.

German Flusseisen.—The German "Flusseisen" wire, the conductivity of which is rather more than 10 per cent. greater than that of puddled iron wire, is very suitable for telegraph purposes, and has also been much applied to telephone lines.

Even the softer kind of Flusseisen wire has a breaking strain five per cent. higher than that of soft iron wire, whereas the harder kind with a breaking strain of 60 to 65 kilos. per □ mm., is also very suitable for conducting purposes on account of the particular tenacity and ductility of this material.

A galvanised Flusseisen wire of 4 mm. has a nominal value of m.35 per 100 kilos., that is to say, 40 per cent. more than puddled iron wire.

With a like weight, however, a rapidity of transmission 10

N.B.—In calculating spans and pitch we have used the formula :—

$$(1)\ \text{Span}\ a = \sqrt{\frac{8 \cdot f \cdot s}{g}} \quad \text{where } g = \text{weight in kilos per metre}$$

$$(2)\ \text{Pitch}\ f = \frac{g \cdot a^2}{8\,s} \quad \text{,,}\ s = \text{span} = \tfrac{1}{4} \text{ of breaking weight.}$$

per cent. greater is obtained, and since the breaking strain is greater by more than one half, whereby the supports may be placed so much farther apart, the higher price is justified under certain circumstances, and may even be quite compensated for by the cheapness of construction of the whole line.

Patent Cast Steel Wire.—For telegraph lines the cast steel wire can only be considered where long spans are absolutely required and unavoidable. Its small conductivity, which is only 9½ to 10½ per cent. of that of copper, counterbalances the advantages derived from its higher breaking strain and high limit of elasticity.

For other purposes its breaking strain, which is for the softer kind 95, and for the harder 140 kilos. per □ mm., will permit of a sectional area only about ⅓ of that of iron wire to obtain an equal breaking strain, and by a reduction in weight so considerable the difference in cost is more than balanced. A puddled iron wire of 4 mm. has not a higher breaking strain than a cast steel wire of the harder kind of 2·2 mm. whereas the former weighs per kilometre 100 kilogrammes, and costs m. 25, the latter only weighs 30 kilos., and costs (at m. 67 per 100 kilos.) only m. 20·10. The former has a conductivity resistance of 12 S.U. and the latter 73·32 S.U.

To obtain an equal resistance of 12 S.U., the patent cast steel wire would require to have a diameter of 4·5 mm., weighing in round figures 125 kilos. per kilometre, and costing (at m. 63 per 100 kilos.) m. 78·75, *i.e.*, more than three times the price of puddled iron wire of like conductivity.

Phosphor Bronze.—In consequence of the great modern development of telephony, and of the special requirements imposed on wire for telephonic conduits, phosphor bronze has been put forward in different quarters as being the most excellent material for telephonic conduits. As it has been attempted on several occasions to apply this material to telegraphy, it may also be compared with others.

Trials made with phosphor bronze wires manufactured by different makers went to prove from the first that breaking strain and conductivity are also with this material in inverse proportion—that is to say, the conductivity resistance increases with the breaking strain.

The most favourable result obtained as to conductivity has been inserted in Table I., and shows a conductivity of 22 per cent. of that of copper, and a breaking strain of 55 kilos. per □ mm.

The highest breaking strain observed was 110 kilos. per □ mm., but on measuring the conductivity of the samples giving this result only 8 per cent. of the conductivity of copper was found, besides which the wire was too brittle by far for the purpose intended.

In order to compare the cost, it may be assumed that this wire was to be had at m. 320 per 100 kilos., or about 50 per cent. more than the price of copper wire. Phosphor bronze wire having about double the breaking strain of copper wire (55 kilos. as against 28 kilos. per □ mm.), it would cost about 25 per cent. less than copper wire, the length and breaking strain being identical. The conductivity of phosphor bronze wire with the same breaking strain and half the section and weight would, however, be only 11 per cent. of that of copper wire.

In comparison with galvanised puddled iron wire, as phosphor bronze wire of 3 mm. would give about the same conductivity resistance as a galvanised puddled iron wire of 4 mm., it would weigh 63 kilos. as against 100 kilos., but the price would be m. 201·60 as against m. 25 per kilometre, or about eight times as much. Besides this disadvantage phosphor bronze wire is, like copper wire, exposed to the danger of being stolen.

If in the case of phosphor bronze wire a point be made of its faculty of withstanding the corrosive effects of atmospherical exposure, and the advantages derived therefrom, galvanised wire does not range second to it in this respect. Phosphor bronze wire affords, therefore, no advantage beyond the higher breaking strain (in proportion as 55 to 40), as compared with common galvanised iron wire.

A comparison with the other iron and steel wires is, after the above, useless.

A comparison with galvanised cast steel wire is treated in its proper place under the head of Telephone wires.

2.—*Telephone Conducting Wires.*

As aërial telephone lines must, in most instances, be led over roofs of houses, across public streets and squares, &c., the requirements imposed on telephonic wires are very exacting; the

Digitized by Google

wire must allow of its being spanned with absolute security between the supports even for the widest distances when traversing public ways, as the breaking of a wire may be attended with the gravest consequences. This method of leading the wires over the roofs necessitates the lightest possible construction of the whole line, and, consequently, the employment of as small gauges of wire as possible, in order to lessen the strain brought to bear on the supports that the latter may be employed of a light description. In order to meet these requirements, which in the case of aërial lines are predominant, the conductivity of the wire, which diminishes with the size of the wire, must be regarded as of secondary importance.

In order to get a clear understanding as to what material is most suitable for aërial telephone lines, and how far one material deserves preference over another, it is necessary first of all to establish what conductivity resistance is necessary, to show that a material answering to all other requirements is also suitable as concerns conductivity.

Practical results of a reliable nature do not appear to have been obtained yet, but it is contended by many that a phosphor bronze wire of 0·8 mm. even, has sufficient conducting power, and that if it be true that no smaller phosphor bronze wire than 1·25 mm. be used, this is done because a wire any smaller would present too great difficulties in handling and fixing on the roofs.

Now, as the results of tests stated in Table I. show that a phosphor bronze wire of 0·8 mm. has a resistance of 164 S.U. per kilometre, it is to be assumed that this resistance is admissible.

As, however, no smaller phosphor bronze wires than 1·25 mm. are used, and these, as shown by the tests before mentioned, have a resistance of 67·4, or in round figures 68 S.U. per kilometre, such sizes of wire have been chosen for the comparison of materials in Table II. that all wires have the same conductivity in round figures of 68 S.U. per kilometre.

Table II. suggests the following reflections:—

Copper.—A comparison with copper shows that a phosphor bronze wire of same resistance has about a fourfold greater weight and costs six times as much as copper wire, while admitting of double the distance between the posts.

Both copper and phosphor bronze wires are equally liable to be stolen in consequence of their high value.

Galvanised Puddled Iron Wire.—To obtain the same resistance as a phosphor bronze wire 1·25 mm. thick, a puddled iron wire of 1·68 mm., or in round figures 1·7 mm., must be employed, the breaking strain of which is inferior in proportion as 40:55, whereas its weight presents no objection. The cost of the galvanised puddled iron wire is only 19½ per cent. of the price of phosphor bronze wire of equal resistance.

Galvanised Flusseisen Wire.—Flusseisen wire has already been much used for telephone purposes. Its particular tenacity and pliancy render even the hard kind, having a breaking strain of 65 kilos. per □ mm., suitable for this purpose. Its conductivity is such that a wire of 1·6 mm. has the same as a phosphor bronze wire of 1·25 mm., or a puddled iron wire of 1·7 mm. The supports may be placed farther apart than with phosphor bronze wire, in proportion as 139:100, or ⅓ farther. The unit of length of Fluesseisen wire of equal conductivity weighs somewhat less than one-half more than phosphor bronze wire, and will bear more on the supports in the same proportion. In comparison with puddled iron wire Flusseisen wire admits of spans ½ longer, and the strain borne by the supports is about 10 per cent. less.

The same length of Flusseisen wire, always of equal conductivity, costs only about ⅕ of the price of phosphor bronze wire, or about 10 per cent. more than puddled iron wire.

Galvanised Patent Cast Steel Wire.—There is no material affords greater security than patent cast steel wire against the danger of broken wires, and the often fatal consequences to any persons happening to be passing through the streets at such times. In consequence of its high limit of elasticity it suffers less through the strain caused by sudden changes of temperature, and its high breaking strain permits of spans over very considerable distances. Its breaking strain is about six times greater than that of copper, three and a half times greater than of puddled iron wire, and all other soft iron and steel wires, three times greater than that of phosphor bronze wire, and two one-fifth times greater than that of Flusseisen wire.

With like conductivity, patent cast steel wire will strain the supports about twice as much as phosphor bronze wire, ¼ more than puddled iron wire, and one-third more than Flusseisen wire. Thus it will be seen the choice of material depends much on whether the greater distances between the supports or the lighter construction of the line is of paramount importance.

With regard to prices, the table shows that patent cast steel wire is fully twice as dear as puddled iron wire, and exactly twice as dear as Flusseisen wire, whereas it only costs about two-fifths of the price of phosphor bronze wire.

If the assertion referred to at the introduction of these remarks, that as concerns conductivity a phosphor bronze wire of 0·8 mm. is sufficient, then a galvanised patent cast steel wire of 1·25 mm. with a conductivity resistances of 156 S.U. will do just as well. A comparison of a phosphor bronze wire of 1·25 mm. with a patent cast steel wire of the same size gives the following result:—

	Phosphor Bronze Wire.		Patent Cast Steel Wire.
Conductivity................	68 S.U.		156 S.U.
Breaking Strain	67 kilos		171 kilos
Weight per 1,000 metres	11 kilos		9½ kilos
Price per 100 kilos	M. 320.		M. 72·
Price per 1,000 kilos	M. 35·20		M. 6·84
Or in proportion as................	100	to	19½

In this case the phosphor bronze wire has less than ½ the resistances of patent cast steel wire, but the resistance of the latter is yet sufficient, and the wire could be spanned over a distance three times as great, being 14 per cent. lighter in weight, the strain brought to bear on the supports would be proportionately less, and the cost 80½ per cent. less (that is to say, phosphor bronze would cost about 6 to 7 times more than cast steel wire).

Galvanised patent cast steel wire is at the present time mostly used in the sizes 2·0, 2·2, and 2·5mm.; but if the minimum limit of conductivity can be placed as low as above stated, cast steel wires of 1·2, 1·4, and 1·6mm. are quite suitable, to which the following figures apply:—

	Patent Cast Steel Wire (Galvanised.)				Phosphor Bronze Wire.
	1·2	1·4	1·6		1·25mm.
Resistances S.U................	168	124	95	......	68
Breaking Strain Kilos.	158	215	281	......	67
Weight per 1,000m. kilos.......	9	12	15½	......	11
Price per 100 kilos. m.	72·	71·	70·	......	320·
„ „ 1,000 metres m.......	6·50	8·50	11·	......	35·20

Compared with a patent cast steel wire of 1·6mm., a phosphor bronze wire of 1·25mm. would have a resistance about ⅓ lower, and weighs 29 per cent. less, but would require 3 times as many supports (though these might be of a lighter description), and cost three times as much.

As a result of the above reflections, it seems to carry conviction that galvanised patent cast steel wire is in all respects the most suitable material for telephonic lines.

A process used in the United States of America for increasing the conductivity of steel and iron wires by means of a galvanic deposition of copper merits some attention. This coating of copper is mostly 0·1mm. in thickness, or increases the size of the wire by 0·2mm. If, for instance, it were intended to provide a cast steel wire 1·6mm. thick, of the harder temper, with such a copper covering (which should not present any difficulty) a coppered cast steel wire of 1·8mm. would be obtained. The sectional area of this wire being 2·545 □ mm., the steel wire would absorb 2·011 □ mm. of said area, and 0·534 □ mm. would be taken up by the copper coating. Copper having a superior conductivity to the harder temper of steel—in proportion as 100:9½—the copper section of 0·534 □ mm. would represent a steel section of 5·621 □ mm., which, together with the section of the original steel wire, viz,, 2·011 □ mm., gives a total section of 8·166 □ mm., corresponding with a wire of fully 3·2mm. diameter.

The coppered patent steel wire of 1·8mm. would thus have the same resistance as a galvanised steel wire of 3·2mm., and the same breaking strain as a steel wire of 1·6mm. It would weigh about 20 kilos. per kilometre, and the strain on the supports would be greater in proportion as 20 to 15, whereas the faculty of spanning would be reduced in like proportion, viz., as 15:20; the conductivity of the wire would, however, be quadrupled (24 instead of 95 S.U. per kilometre). As compared with a phosphor bronze wire of 1·8mm., such a coppered steel wire of 1·8mm. allows of being spanned over double the distance, weighs fully 10 per cent. less, has a conductivity resistance about ¼ less, and costs hardly one-third part.

In conclusion, it may be mentioned that aërial lines of wire fixed to insulators can only be regarded as temporary, at least for large cities, as the number of wires in many places has already assumed such proportions that a still further extension seems hardly possible. The necessity of placing the wires underground in large cities is being more and more felt, and electricians will have to apply themselves seriously to the study of suitable constructions of cables underground to do away with the inconvenience experienced from aërial lines.

NOTE.—Money is given in German marks, equalling one English shilling.

THE CRYSTAL PALACE EXHIBITION.

With the formal visit of the Speaker and members of Parliament last Saturday the Crystal Palace as an exhibition of electrical appliances may be said to have terminated. For another week the show was kept open for Whitsuntide holiday-makers; but the process of packing up, which had already begun, will by the close of this week be well nigh completed. It is too soon to offer an opinion as to the scientific results of this remarkable gathering; but considered merely as an exhibition we believe we are correct in saying that it has been in every respect a great success. Exact statistics are not before us of the number of visitors in excess of the average ordinary attendance at the Palace; but any one who has paid chance visits to it during the past three or four months could not fail to notice the unaccustomed crowding and the unwonted interest taken in what was going on. The cost of management, no doubt, has been largely augmented during this period, but we have reason to believe that, on the whole, the proprietors will not experience any financial disappointment as a consequence of their bold venture.

We call it a bold venture, for one might have supposed that the telegraph and all that pertains to it had long ago ceased to be a wonder, and that, even with an attractive show of electric lighting thrown in, the exhibition would scarcely be considered popular. This, however, has not proved to be the case, the visitors in the day time being quite as numerous as those arriving specially for the night time display. It is evident, therefore, that the inner life, if we may so call it, of signalling messages by electricity is still as great a mystery to the public as ever. Following the groups from stall to stall, the wonderment, or, as some would say, the ignorance, displayed by people otherwise well informed was itself a thing to marvel at. Fortunately for the organisers of exhibitions of every kind, the average public trouble themselves little about why and how their necessities are ministered to, but are very willing to be shown and to take an intelligent interest in the proceeding, if only you can arouse their curiosity. This the electrical exhibitions, both at Paris and here at Sydenham, were eminently calculated to do. The multitude of beautifully constructed apparatus, as manifold in their design as puzzling in their application, evidently took everybody by surprise, and wherever an attendant was placed to answer inquiries his task was by no means a light one. The fewness of these attendants has in our opinion been a drawback to such exhibitions. Wherever there was an attendant there the crowds would congregate, and the people who disdained his assistance were as rare and as isolated as are those very superior parties who would do Notre Dame without a commissionaire, or climb the Matterhorn without a guide.

For similar reasons the lectures were very well attended, although they were not uniformly framed on popular lines. This experiment was quite a novel one, and when first mooted was chiefly suggestive of the dreary ineptitudes of the Polytechnic. But the result was quite different; and on the subject of electric lighting especially the interest awakened was very general. We would fain hope that nothing that was said on those occasions contributed in any way to the mania which has since set in on the Stock Exchange. Doubtless the lecturers believed in their own predictions; but the predictions of scientific men are better suited for the atmosphere of science, where speculations of that kind are not interpreted as encouragement to speculation of a quite other kind, than for the ears of an unlearned and impressionable multitude, who are apt to take things literally, especially where there is a seeming prospect of making money by them.

The display of electric lighting was, we need hardly say, superior to anything of the kind ever witnessed before. Both for the variety of the lights, the pains bestowed upon their decorative capabilities, and the advantageous positions they occupied, the English exhibition was far ahead of its predecessor on the other side of the channel. The best that both arc lights and incandescent lights could do in the circumstances, or indeed in almost any circumstances, were here fully developed; and we should imagine that the exhibitors themselves had as much satisfaction in the opportunities afforded them of displaying their lamps to advantage as the public had in seeing them. The people who hastily concluded that the hideous contrivances which first made us acquainted with electric lighting out of doors, and which are even now not quite banished from the centre of the metropolis, were the inevitable adjuncts of this new favourite, must have been agreeably surprised at what they saw at the Crystal Palace. It turns out, indeed, that of all the methods yet devised for illuminating our houses, this, the latest, lends itself most easily to the demands of good taste. On every hand it was declared that the lamps were beautifully mounted and tastefully arranged. In several instances they were superb, and the utterly-all-but community were constrained to admit that there is still some hope for modernism when it is capable of such charming inventiveness as this. Moreover, the colour of the lights was in most instances irreproachable, and objections on this score,

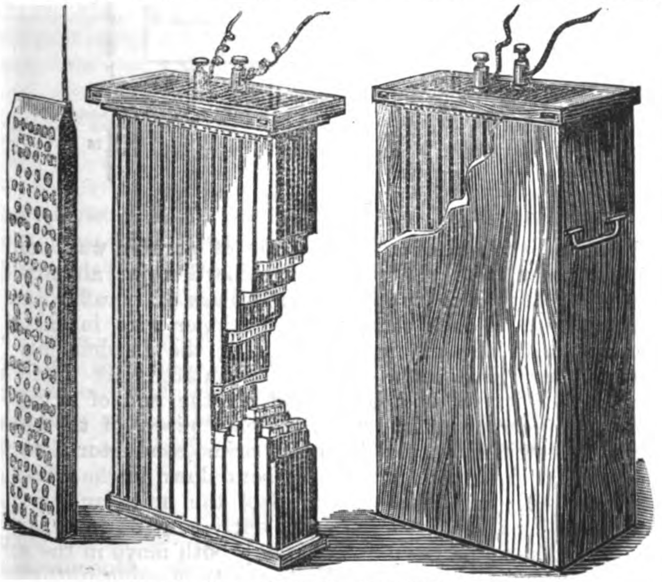
Digitized by Google

which were frequent and loud twelve months ago, are now no longer heard. The utility of the arc light for outdoor lighting is beyond all question; the attractiveness of the incandescent light for indoors is now rendered almost equally sure. Our notices of the various exhibits have not kept pace with the exhibition itself, but with the enlarged space now at our command we hope to give fuller descriptions of many interesting objects which as yet we have scarcely been able to mention.

Since writing the above we learn that efforts are being made to extend the exhibibion over another three months. We sincerely hope that the appeal which the managers are now making to the exhibitors to allow their property to remain on view during the period named will meet with a favourable response.

ACCUMULATORS FOR INDUSTRIAL PURPOSES.

The following account of some improved accumulators which have been constructed with corrugated plates was communicated by M. N. de Kabath to a recent number of *L'Electricien*:—"The battery is made up of a number of vertical plates, arranged as shown below. Each plate is composed of a series of strips of lead, 1-10th of a millimetre thick, and of a convenient length. These small lead plates are alternately corrugated and flat, and are placed one against the other until they finally form one large plate, 8 or 9 centimetres wide, containing from 80 to 100 of the small plates. They are kept in position and firmly held by a perforated lead plate, which entirely surrounds them at the same time that it permits free circulation of the liquid (see Figure). The vertical type of battery



Kabath's Accumulators for Industrial Purposes.

is composed of twelve such plates, connected alternately to the two terminals. The two end plates are plain sheets of lead, thus making the total number of plates fourteen. They are solidly fixed to the cover at the top, and at the bottom are held in position by placing them in an insulating glue formed of black resin and paraffin. In the cell for laboratory purposes the plates are smaller, and only six in number. They are also placed in a glass jar, the better to study the action consequent on charging or discharging. In the cell constructed for industrial purposes, the outer case is of wood with leaden covering and furnished with handles, the better to move it about. The plates are about 40 centimetres high, 85 millimetres wide, and 1 centimetre thick. The battery weighs 30 kilogrammes with box, and without liquid, and abcut 35 kilogrammes with water combined with 1-10 acid, ready for work."

CORRESPONDENCE.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Dr. Shettle's letter to you of 25th of April last has been unanswered for the following reason:—In proof that electricity is matter, I had drawn his attention to the contracting action of electricity around an insulated metallic ball at the time an insulated conductor is brought near to it. Dr. Shettle has attributed this action to friction, but this is a palpable absurdity in the light of the facts concerning the nature of electricity known at the time he wrote, but as I have been making experiments, by which I have discovered more information about the nature of electricity, I delayed replying to Dr. Shettle's letter until my own arrangements for publishing my new experiments were completed.

These new experiments, and the discovery made through them, depend on the trustworthiness of the insulated gas-flame as a test of the direction in which currents of electricity move. Your readers will, no doubt, remember the challenge of

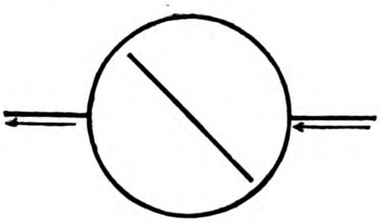


FIG. 1.

the accuracy of this test which Professor Silvanus P. Thompson made, as published in *The Electrician*, Vol. VIII., page 141, in these words:—"As to your experiments of the year 1839, there is an unproven assumption underlying the whole of them, namely, that a test flame moves in the direction in which electricity moves, which may or may not be true, and which is no test at all until you have by some other and independent process proved that the electricity is really moving in the direction in which you assume it does." This challenge compels me, in the first place, to adduce proof regarding the trustworthiness of the gas flame test.

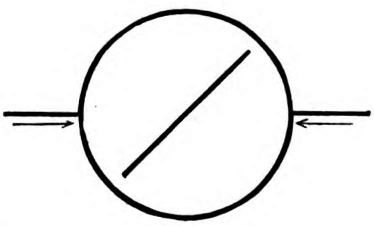

FIG. 2.

Every electrician who has had any experience in the employment of dynamo machines to keep on operation a series of arc lights has been forced by facts to believe that a current of electricity goes out by the one set of wires, technically called the "leads," and that the current comes back to the machine by the return wire. Further, on inspecting the arc-lights in action every electrician knows which way the electricity is moving, because the one carbon becomes concave at its point and the other becomes convex. If these carbons be placed in a horizontal position and in a vacuum the particles of carbon continually rush from the concave point to the convex one, so that the convex point diminishes in size, while the convex one grows in bulk, and if the light be magnified and thrown on to a screen the human eye sees this rushing of the particles of carbon from the concave to the convex point. This is ocular proof that the current of electricity is moving in the direction indicated by the particles of carbon. Again, when a galvanometer is employed to indicate the direction in which a current of electricity is moving it gives us the information in the following manner: When the current is going through the wire from the

Digitized by Google

right-hand to the left, then the top of the index of the galvanometer moves from the perpendicular position towards the left-hand, as shown in Fig. 1.

When the current is going from the left to the right, then the galvanometer index moves so that the top of it goes from the perpendicular towards the right-hand, as shown in Fig. 2.

These two instruments, the arc light and the galvanometer, serve the purpose of testing the accuracy of the gas flame test in the following manner:—Fig. 3 represents a glass tube with the full-sized gas flame placed between two wires for testing the direction of a current of electricity

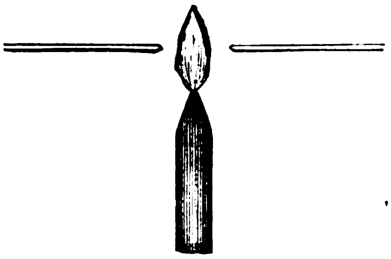

Fig. 3.

when all the three instruments are applied in conjunction. When the points of the arc light and the galvanometer indicate that the current of electricity is going from the right-hand to the left the flame is driven from the right hand to the left, as indicated by Fig. 4.

When the points of the carbon and the galvanometer indicate that the current of electricity is going from the left hand to the right, then the flame is driven from the left hand to the right, as indicated by Fig. 5.

This similarity of action of the insulated gas-flame with the action of the carbons and the galvanometer is a sufficient

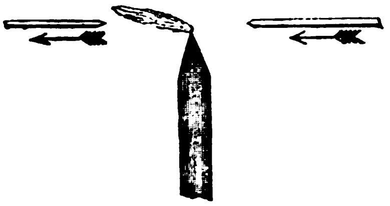

Fig. 4.

proof of the trustworthiness of the gas-flame as an indicator of the direction in which currents of electricity move.

The new experiments about to be described were begun with the intention of discovering the cause of the phenomenon of the Leyden jar. As Franklin had by his invention of the Leyden jar with movable coatings determined that the phenomenon of the Leyden jar resided in the glass of which it is made, I wished to test this in another way; so with a large Leyden jar, measuring seven inches in diameter, and thirteen inches in height, I ascertained how many charges of electricity of a unit jar it took to charge the

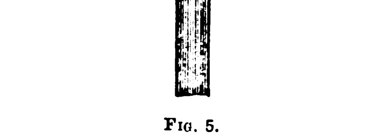

Fig. 5.

large Leyden jar. I then filled this Leyden jar with melted paraffin wax up to the mouth of it, so that all air was excluded from the interior of the jar. After it had been allowed to stand for two days, so that the paraffin wax was cold and hard, I then tested the jar's capacity for holding electricity by charging it by means of the same unit jar, and found that there was no difference in the number of charges required to fill the paraffin-loaded Leyden jar. This experiment demonstrated that the air inside a Leyden jar does not affect the amount of charge the jar is capable of holding. I now emptied the paraffin wax out of the jar, and placed inside of it fourteen pounds of small scrap iron, which amount just reached to the top of the tinfoil inside the jar. I now tested the jar with the unit jar charges, and found that the fourteen pounds of scrap iron made no difference in the number of unit jar charges required to charge the Leyden jar; hence there is proof that the inside lining of tinfoil must have very little to do with the amount of charge of electricity that a Leyden jar can take. The phenomenon of the Leyden jar, therefore, depends upon the glass of which the jar is made. There is another peculiarity in Leyden jars which requires to be noted here, as it has an important bearing on the explanation of the succeeding experiments, namely, the well-known fact that a Leyden jar will not take a charge of electricity if the jar be thoroughly insulated. I tested this by coating the foresaid Leyden jar all over the outside of it with a thick coating of paraffin wax, and then placed the jar on the top of pillars of paraffin wax. I then found that the jar could not be charged when in this state, but on passing a sharp-pointed wire through the coating of paraffin till it reached the tinfoil coating of the jar, then the jar was able to take a charge of electricity. The reason of the foregoing is, that electricity will not move in any direction unless facility be given to it to form a current. The sharp wire passed through the paraffin to the tinfoil coating, and the other end of the wire put to earth, gave the facility for a current of electricity to pass through the jar, and then it took a charge.

Fig. 6 is a representation of the apparatus by which the new experiments were made. A is a brass ball attached to the prime conductor of a frictional machine, by which a supply of electricity was obtained. B is a glass tube with insulated gas flame on the top of it. C is a unit jar for measuring the quantity of electricity passing. This jar is

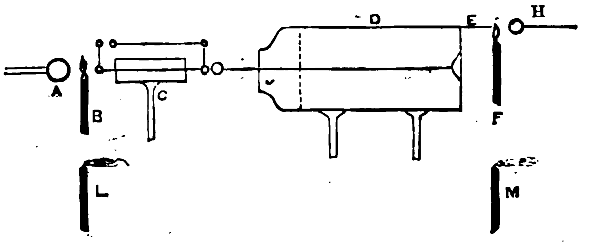

Fig. 6.

placed on the top of a stand made of paraffin wax, and is thereby insulated. D is the large Leyden jar already described. It is also supported on pillars of paraffin wax to insulate it. E is a sharp-pointed copper wire in metallic contact with the external coating of the Leyden jar. F is another glass tube with an insulated gas flame on the top of it. H is a brass ball, on the end of a copper wire, in communication with the gas pipes of the house. When electricity passes from the prime conductor A to the unit jar, the flame B is violently bent down in the direction shown by L; and when a charge of the unit jar C passes into the jar D, the flame F is violently bent down as shown by M. The flame B and the flame F both move in the same direction, indicating that, while electricity is going in through the flame B, electricity is coming out of the jar D through the glass and the flame F. At the first discharge of the unit jar C into the jar D the flame F is as much bent down as the flame B, but on each succeeding charge of the unit jar going into the jar D the flame F becomes less and less affected till at last the flame F stands upright; the jar D is then fully charged. The moment electricity ceases to go into the Leyden jar D, that instant electricity ceases to come out through the glass and go by the wire E through the flame F. In the published document which I sent to Faraday, Arago, and others, in 1839, I stated that, from the experiments then made, I had reason to believe that *static induction* had no existence in fact; that the phenomena of electricity were all produced by one electricity; and that it was not like the one electricity of Franklin, who imagined that electricity and matter did each possess a repellent power within themselves, whereas I maintain that electricity has no repellent power.

Digitized by Google

All the phenomena supposed to be from repulsion arise from attraction. But to return to the facts of experiment. The phenomenon of the Leyden jar does not arise from *static induction*, because *static induction* requires the glass to be impervious to electricity, that is, that one kind of electricity accumulates on the inside of the glass of the Leyden jar, and that the other kind of electricity is induced to accumulate on the outside of the jar, and that neither of the electricities can pass through the glass of the jar. Now, it is manifest that the electricity does pass through the glass of the jar, because the two gas flames B and F both bend in one direction. B bends towards the right hand, showing that electricity is going into the unit jar. F bends towards the right hand, showing that electricity is coming from the outer coating of the jar. Where is it coming from? It must be coming through the glass. This is proved by the following experiment, and it puts an end to the myth called *static induction*:—

The same arrangement of apparatus as before is continued, except that a plug of paraffin wax is placed in the mouth of the jar D, and there is inserted into it a piece of No. 16 copper wire (see Fig. 7) through the paraffin plug, so that the wire is insulated. Six inches of the wire extend inside the jar, and it is in contact with nothing but the air inside the jar; the outer end of the wire is sharpened to a fine point. With this arrangement of the jar D a different result takes place. At first the flame F is affected in the same way as in the former experiment, and, as each succeeding charge of the unit jar goes into the jar D, the flame F becomes less and less affected, until the flame F stands nearly erect; but when the number of charges of the unit jar have passed into the jar D, which formerly was sufficient to charge the jar D, it is found that the flame is still

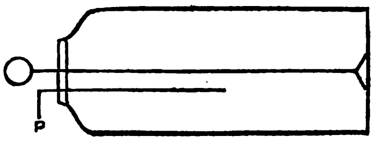

FIG. 7.

affected by every succeeding charge of the unit jar which goes into the jar D, and although the experiment be carried on for hours, yet it is found that an escape of electricity passes through the flame F every time a charge of the unit jar passes into the jar D. As I have said, the experiment may be carried on for hours, and yet electricity will continue to escape through the flame F. Hence it is manifest that it is a part of the electricity which is going into the jar D which comes out through the glass and passes through the flame F. From the time the charging of D is commenced a small stream of electricity rushes out by the pointed wire P. There is thus a current of electricity formed through the interior of the jar. As long as provision is made for this current of electricity to go on in the interior of the jar a part of the electricity comes out through the glass and goes through the flame F. When a piece of paraffin wax, made for covering the wire P, is placed on the point of it, this stops the electricity from coming out by P, and this stops the internal current in jar D; then no electricity will go into the jar D from the unit jar, and no electricity comes out through the glass to the flame F. It was proved that electricity will not go into an insulated Leyden jar to charge it, because there was no current of electricity through it, no outlet through the glass while the jar was insulated. So with the charged jar D; because the electricity inside of it is of the same potential as the potential of the current by which it is being charged. Electricity stops going into the jar, and this stops the current of electricity within the jar. We can understand that electricity will not go into an insulated Leyden jar, because the insulation prevents the glass permitting a part of the electricity to pass through it; and, therefore, no current of electricity can be formed through the jar, and because there is no path for a current, the electricity will not enter the jar. And so with the charged Leyden jar, when the potential of the electricity within the jar has risen to the same potential as the current of electricity that was going into the jar, it is obvious that the jar can hold no more electricity, and hence the current going into the jar stops, and with the stoppage of the current going into the jar, the current coming out through the glass of the jar also stops. But, seeing that the potential of the electricity inside the jar is so much greater than that of the outer coating of tinfoil of the jar, and that while the jar was being charged electricity did come out through the glass and outer coating of the jar, what prevents the electricity from coming out through the glass and outer coating of the jar after the charging current stops going into the jar? The explanation of this mystery must be looked for in the electricity's own action. As has been already stated, when the first charge of the unit jar passed into the jar D, the flame F was violently affected, showing that most of the first charge of the unit jar passed out of D through the glass, but as each succeeding charge of the unit jar entered the jar D, the flame F became less and less affected, showing that there is in the electricity which entered D some power of contraction which increased in amount as the potential of the electricity within D increased, until, at last, this contracting power had sufficient force to prevent any electricity from passing out through the glass. Now this contracting power can be no other power than that of the electricity's attraction of cohesion for its own particles; and hence it is manifest that electricity is a peculiar kind of matter, because it possesses attraction of cohesion for its own particles, and yet it is not acted on by the law of gravitation. This letter is already too long for your pages, but if its contents do not convince Dr. Shettle that he is wrong in maintaining that electricity is energy and not matter, I may in another letter enter into details in criticising Dr. Shettle's theory of electricity, in the explanation of which he has used a great flow of scientific words which result in the confounding of some scientific facts.—Yours, &c., JAMES JOHNSTONE.

Experiment Rooms, 1, James's-square,
Edinburgh, May, 1882.

DIMENSIONS OF A MAGNETIC POLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I see on page 27 of your last number that Professor Clausius objects to Maxwell's dimensions of magnetism in the electrostatic system of units, and that he appears to be supported by Professor Everett, the author of a valuable work on units. The argument, as stated by the latter, is that since

$$\text{pole} \times \text{length} = \text{current} \times \text{area},$$

we should have the dimensions of pole = L × dimensions of current. This comes out right in the electro-magnetic system, but quite wrong in the electrostatic.

The error appears to lie in the neglect of the distinction between magnetic force and magnetic induction. The latter is μ times the former, μ being the magnetic "permeability" of the medium. Now, a small plane electric current and a small magnet produce similar fields of force in a particular medium, so we may choose a certain strength of current that shall make the fields of the same strength externally. But a remarkable difference comes in when we change the medium. In the case of the closed current the magnetic force remains always the same, the induction, therefore, varying directly as μ. But with the magnet it is the induction that remains the same, whilst the force varies inversely as μ.

So we have

$$\text{magnetic force} = \frac{\text{current} \times L}{L^2} = \frac{\text{current}}{L},$$

and also

$$\text{magnetic force} = \frac{\text{magnetism}}{L^2 \mu}.$$

Consequently,

$$\text{magnetism} = \text{current} \times L\mu,$$

or $$\text{pole} \times L = \text{current} \times L^2\mu,$$

or $$\text{pole} \times \text{length} = \text{current} \times \text{area} \times \mu,$$

Digitized by Google

so that the magnetic moment of the current is really μ times that of Professors Clausius and Everett.

Maxwell determines the dimensions of the quantities from relations in which μ does not appear, and from the ratio of two of them, viz., the magnetic induction and the magnetic force, the dimensions of μ are found to be $\frac{T^2}{L^2}$ in the electrostatic system, and *nil* in the electro-magnetic. This naturally agrees with

$$\text{pole} = \text{current} \times L\mu.$$

A very similar thing occurs in the electro-*magnetic* system if we do not attend to K, the co-efficient of dielectric capacity. Thus, from the dimensions of electricity being $L^{\frac{1}{2}} M^{\frac{1}{2}}$, and from

$$\text{electric potential} = \frac{\text{electricity}}{\text{distance}}$$

we might hastily conclude that the dimensions of potential were $L^{\frac{1}{2}} M^{\frac{1}{2}}$, whereas Maxwell gives $L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-2}$. The explanation is that a given charge in a medium of capacity K gives a force $= \frac{1}{K} \cdot \frac{\text{electricity}}{L^2}$, and, consequently, potential $= \frac{\text{electricity}}{K\,L}$. K being a numeric in the electrostatic system, its neglect does not cause error there, but in the electro-magnetic system relations not containing K should be used. Like μ in the electrostatic system K in the other system has dimensions $\frac{T^2}{L^2}$, the product $K\mu$ being, therefore, $\frac{T^2}{L^2}$ in both systems alike, the reciprocal of the square of Maxwell's velocity of propagation of disturbances.

In Ampère's theory of magnetism, magnetised molecules are simply molecules with currents flowing round them, *i.e.*, small closed currents. But these currents are not of constant strength, but vary according to the magnetic force passing through them from external causes, so as to preserve the amount of indication through them constant. This follows from the currents meeting with no resistance. If a magnetised molecule were replaced by an unchangeable closed current, they would only produce equal external force in some particular medium, and could not be generally exchangeable. —Yours, &c. OLIVER HEAVISIDE.

3, St. Augustine-road, N.W., May 27, 1882.

CURATIVE ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I fail to see how the assertion that "it has never yet been shown that magnetism—even as developed by the most powerful permanent or electro-magnets—exerts any physiological action whatever" can be *partially* correct. Either the fact has been demonstrated or it has not. In Dr. Shettle's letter I find nothing that I can accept as evidence in favour of the affirmative proposition. I am well acquainted with Faraday's experiment, in which currents of electricity are developed by rotating a coil of wire, and I freely admit that these magneto-electric currents are capable of exercising a physiological action; but I cannot perceive how this experiment can be logically quoted "by way of testifying to the influence which terrestrial magnetism exerts upon the blood and tissues of the body." I am also well aware that the animal organism may form part of the magneto-static circuit—*i.e.*, may be traversed by magnetic lines of force, so that a magnetic needle may be affected by another magnet acting through the human body. I have heard also that by making this magnetic needle portion of a "tolerably sensitive galvanometer" the attempt has frequently been made to substantiate the delusive statement that magnetism is equivalent in its effects to currents of electricity. But these facts do not in any way justify the conclusion that the application of magnets to the human frame is attended with the production of any physiological or, possibly, curative effects. In the production of electric currents a conversion of energy invariably occurs, and this energy may be and sometimes has been utilised as beneficially modifying the conditions of animal life. When, however, the animal body is made to form part of a magnetic circuit, not only is it impossible to demonstrate the production of any physiological effect, even with the most powerful magnets, but, if we choose to assume that such effects occur, we are forced to the conclusion that the energy utilised in their production must be that of the vascular or circulatory system, or, in other words, that the arterial and venous flow must be more or less impeded.

Dr. Shettle appeals to experimental results, *inter alia* those which he observed in his own case. To these I am bound to give close and careful consideration. I accept Dr. Shettle's facts without reserve; but I cannot accept the deduction he obviously arrives at from them. Whilst I have a very low opinion of the curative effects of magnets, I have a very high opinion of the beneficial action of *flannel*—especially new flannel—in many of the ailments which flesh is heir to. Has Dr. Shettle tried the flannel without the magnets? If he will substitute for the latter the "pieces of whalebone," I am inclined to "back" the flannel-whalebone combination. I hope even at some future period to give some marvellous cases of cure effected by it. And it may be pertinent to observe that the physiological action of flannel, in stimulating the skin by frictional and probably also by electrical agency, is, unlike that of magnets, beyond any doubt or question.—Yours, &c., DESMOND G. FITZGERALD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent, Mr. Donovan, has failed to perceive that which my words conveyed, viz., that I adduced facts, and not opinions, in substantiation of the value of magnetism as a therapeutic agent.

The laws governing magneto-electricity are bound to hold good whether in a living body or out of it, and until those laws can be set aside magnetism must act in the manner I described in my letter of May 20.

A little consideration of the principles of magneto-electricity will, I am sure, convince Mr. Donovan that his method of conducting his experiments must be fatal to the production of any physical results.—Yours, &c.,

RICHD. C. SHETTLE, M.D.

Reading, May 27, 1882.

STORAGE BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would the Editor or some subscriber be kind enough to explain how to make and charge storage batteries or accumulators.

I should like them to occupy as small a space as possible, so as to be portable, as I am an amateur, and want them to be handy.

Please say whether a high or low electromotive force dynamo machine is best for charging.—Yours, &c.,

W. BARTON.

Waterloo-place, Hill Foot, Sheffield,
May 29, 1882.

THE GRAMME MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have now the pleasure to inform you that at a meeting of the directors of the Anglo-American Brush Electric Light Corporation, held at these offices to-day, the following resolution was unanimously adopted, viz.:—"The British Electric Light Company (Limited) having issued notices to several of the licensees for the sale and users of dynamo machines manufactured by the Corporation, which notices claim that such dynamo machines are infringements of the 'Gramme' patent of June, 1870, belonging to the British Electric Light Company, and the directors of this Corporation being advised that such a claim on behalf of the British Electric Light Company is utterly untenable, resolved: That this Corporation is prepared to guarantee the licensees for the sale and users of dynamo machines manufactured by this Corporation against the claim of the British

Digitized by Google

Electric Light Company."—Yours, &c. (for the Anglo-American Brush Electric Light Corporation, Limited),
H. W. Tyler, Chairman.
William J. Cordner, Secretary.
Belvedere-road, Lambeth, May 31, 1882.

THE LATE MR. C. HOCKIN.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As an old school fellow and college friend of the late Mr. Charles Hockin, I have read with much interest and pleasure the appreciative remarks upon him in your issue of the 6th May, and I beg leave to mention one or two circumstances of his early career, omitted in your article. You state rightly that he went to Cambridge from Aldenham Grammar School, but his first school was Mr. Ogle's, Loudoun-road, St. John's Wood (now removed to Sevenoaks), where he had the opportunity of good elementary instruction in natural science from Mr. W. Tegetmeir (now known as an authority on birds). He showed at Cambridge very high mathematical ability, and I was assured on the best authority that, while he appeared only as third wrangler in the Tripos of 1860, yet he was decidedly first in the *Problem* papers, which would, of course, stamp him as the first mathematician of his year. His acquaintance with natural science in general, physical, chemical, and biological, was remarkable. With all this, his modesty, as you say, was conspicuous. He was, too, a most amiable man, and always showed consideration for the feelings of others. I never remember him to have made an invidious or an unkind remark to, or of, anyone. One can well understand that he was a "thorough favourite in his profession." Hoping you will kindly find space for these few lines—Yours, &c.,
A Former Scholar of St. John's.
Arnesby Vicarage, May 31st, 1882.

EDISON'S ELECTRIC METERS.

Mr. F. Jehl, who has long been assisting Mr. Edison in his laboratory work, has recently furnished us with a considerable amount of information in relation to Edison's work on meters. This information is issued in the shape of a pamphlet for private circulation; but, by the author's permission, we are allowed to reproduce that part which is believed to be interesting to general readers. Although we have from time to time referred to Edison's work in this direction, and illustrated his apparatus, as shown at Paris and at the Crystal Palace, it will be best to again describe the instrument, inasmuch as improvements and modifications have been recently introduced. We also give details as to the method of using it.

The meter is divided into two compartments. The first, or the one on the left side, is termed the monthly cell. This is taken out every month by some *employé* of the company, and another cell is substituted for it. The one taken out is returned to the station, where the plate that has received the deposition is weighed. The cell on the right hand of the meter is termed the quarter yearly cell, and is a check cell. The party who inspects the monthly cell has no access to the quarter yearly cell. This quarter yearly cell is taken out every three months and the deposit weighed. Its deposit must bear a certain proportion to the sum of the monthly meter deposit for those three months. If its deposit does not agree in proportion to the monthly cell there is something wrong, or somebody has tampered with it. Thus we see the object of this auxiliary cell. In Fig. 1 A is the monthly cell, and A^1 is the quarter yearly cell. B^1 and B are compensating resistances, the object of which will be explained further on. In the small meters (for 25 lights), the compensating resistance is 7·5 ohms at zero, and all measurements of resistance should be made at zero, or reduced to it. In the large meters (for 50 lights) the compensating resistance amounts to 7· ohms at zero.

C and C^1 are the respective shunts from which the cells A and A^1 receive their current. The shunt C has a resistance of ·01 of an ohm, while the shunt C^1 has a resistance just one-fourth of that, ·0025 of an ohm. We see thus why one cell receives four times as much current as the other, one shunt being four times as large.

D is a thermo arrangement which Mr. Edison has devised in order to prevent the freezing of the sulphate of zinc solution in the winter. It consists of a strip of brass and

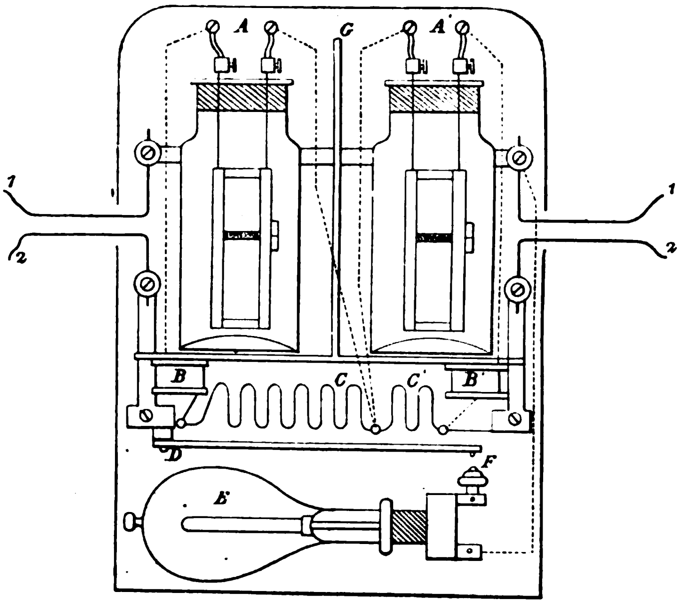

Fig. 1.—Edison's Electric Meters.

steel rivetted well together. Now, one of these two strips expands more than the other. It, therefore, bends in one direc-

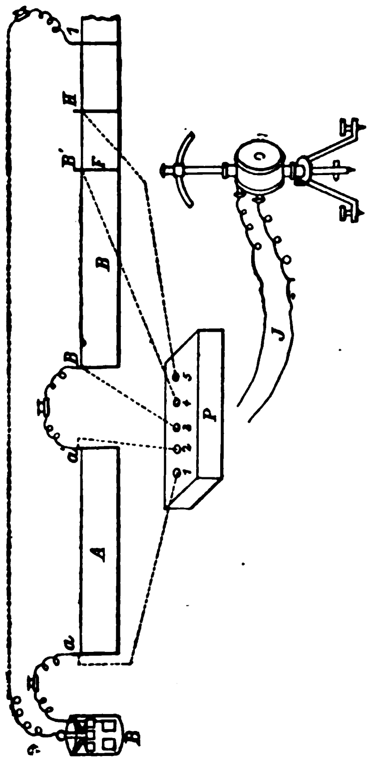

Fig. 2.—Showing Method of Making Meter Shunts.

tion when heated, and as the other strip contracts more than the former when there is a decrease in temperature the combination bends in the opposite direction. It is, therefore, so adjusted, that where the temperature of the atmosphere is about 42° F. it bends and makes contact at the point F, which completes the circuit through the lamp E. The lamp heats the meter, and the heat takes effect on the thermo strip, which then breaks the circuit again, until the heat is dissipated

Digitized by Google

1, 1^1, 2, and 2^1 are the places where the main lines enter and return. G is the partition which divides the two cells from each other.

The shunts used in the meters have a resistance of ·01 of an ohm at about 85° F., and simply consist of a band of German silver. It is necessary to adjust each one with a standard resistance, as one cannot rely upon the length, thickness, and breadth of the band, and the alloy is not equally distributed throughout the whole length, nor is its diameter exactly the same at different parts. The best manner to make a shunt is to put a band of German silver in circuit with a standard shunt or a standard resistance, including a battery, and take your deflections with a high resistance reflecting galvanometer. Fig. 2 will illustrate the best plan. Here we have the battery B, which ought to be a constant one, such as a Daniell, with the standard shunt A, and a band of German silver B, which we wish to adjust so as to make it equal to the one A. Connect in series, and the circuit is complete. Now we connect by means of small wires at a and a^1 at the standard shunt the two ends of the reflecting galvanometer G and get a deflection, suppose

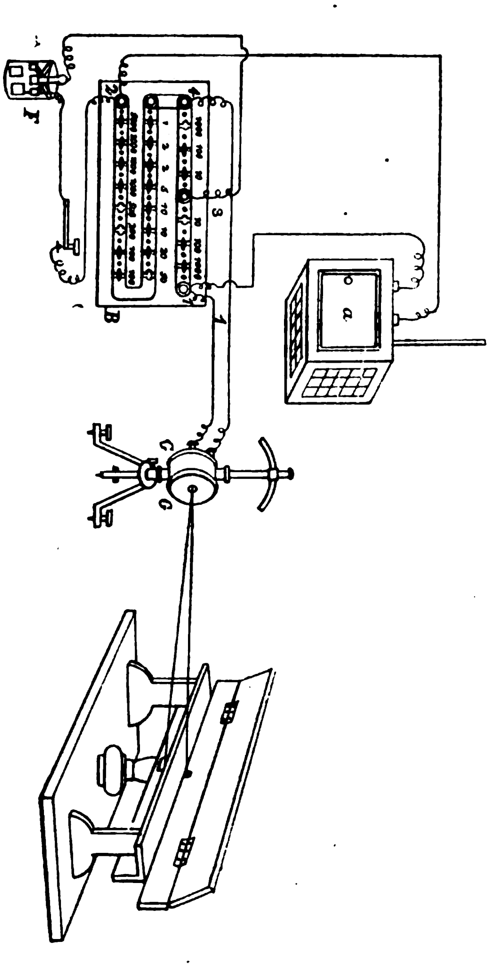

Fig. 3.—Showing Method of Adjusting Compensating Resistances.

300. We then connect the galvanometer to the wires leading to the band of German silver at B and B^1 and notice the deflection. If it be not the same as our standard one, we move the wire F, which is capable of sliding up and down, until we have a deflection equal to the standard. Care should be taken that in handling the band it is not heated by the hand, as the temperature of A should be the same as that of B. Having determined the point which makes both shunts alike, the wire F is then carefully soldered. This is a shunt with a resistance of ·01 of an ohm, but it is also required to have one which equals ·0025 of an ohm. The two shunts are generally made from one strip, for where we leave off on the large shunt we begin with the small one; for instance, having soldered the wire F in the figure, we take another wire with a slit in and place it about H. And another small wire at the point H. Now we get the deflection between B^1 and H, and adjust it so that it gives a deflection one fourth of the deflection given by the standard. P in the figure is a block of paraffin, with 5 holes containing mercury, and the extremities of the wires immersed into them, thereby saving the trouble of connecting the galvanometer terminals with the wires, and also assisting towards great rapidity in manipulation. For one has only to put the ends of the galvanometer into 1 and 2 and we get the deflection between a and a^1; when they are immersed into 3 and 4 we get the deflection between B and B^1; and when into 4 and 5, the deflection between B and H. It may be noticed that before beginning to adjust a strip of German silver, it should be heated to redness over a Bunsen burner, and then the oxydized surface cleaned by immersing it in some dilute nitric acid.

In making and adjusting compensating resistances one must have them in a place where they are not subjected to a variation of temperature, in a small box, for example, where the two extremities lead out as shown in Fig. 3, which also shows how the connections on the Wheatstone bridge are made, when connected for measuring resistance. The box a contains the compensating resistance which we have to adjust, there being a thermometer in the box in order to ascertain the temperature. The two ends of the resistance are then connected to the points 1 and 2 on the bridge, between 3 and 2 a battery is inserted with a key for making and closing the circuit, and between the points 1 and 4 the reflecting galvanometer. Suppose the bridge B at a temperature of 18° per cent., and we also find that our temperature in the box A is 18°. Our compensating resistance must be adjusted to 8·01 ohms if its resistance is or is supposed to be 7·5 ohms at zero. For we know that the difference between 0° and 18° per cent. is on the Fahr. scale 32·4°, and by the table given below we see that the constant for thirty degrees is 1·0650, and for two degrees 1·0042. We, therefore, add the fractional part of the latter to the constant for thirty degrees, which makes

$$1·0650 + ·0042 = 1·0692$$

and this multiplied by 7·5 equals 8·01 ohms.

We can arrive at the same results and with more precision without having to convert Cent. degrees into Fahr. degrees by employing Dr. Mathiessen's formula:—

The resistance R of the metal at the temperature T expressed in degrees Centigrade may be calculated from the resistance $\surd$ at 0° Centigrade.

$$R = \surd(1 + T \cdot 00\ 3824 + \cdot 00000\ 126\ T^2)$$

Thus our resistance at 0° C is 7·5 ohms, and we want to see what it is at 18°. We therefore multiply 18 by ·003824 18. × ·003824 = ·068832; adding 1· we have 1·068832; now adding to this the product of 18^2 by ·00000126 we have 18 × 18 = 324 × ·00000126 = ·000 50824, and this product added to 1·068832 we have

$$\begin{array}{r} 1·068832 \\ ·00050824 \\ \hline 1·069 \end{array}$$

Therefore, our constant is 1·069, and this multiplied by 7·5 = gives about 8·01 ohms. If it were the compensation resistance for the 50 light meters we would multiply the constant 1·069 by 7, which would be 7·48 ohms.

An example may be given of the use of the meter. Thus, say a meter, whose number is 5, was put in Mr. J——'s house, at 57, Holborn-viaduct, on the 20th of March, 1882, and the plate's weight was as follows:—Monthly plate, 90,300 millegrames; the quarterly plate's weight 90,400 millegrammes. Now, at the end of the month, on the 20th of April, the monthly one was taken out and weighed; its weight was 91,400 millegrammes, that being an increase of 1,100 millegrammes, and this, divided by 1,336, gives us the current consumed, which is 823·3.

The following table will help to compute the variation of

resistance of wires at varying temperatures, from a low temperature to a higher one:—

To increase from lower temperature to higher multiply the resistance by the number column 2 (degrees F.)

No. of Degrees.	Column 2.	No. of Degrees.	Column 2.
0	1·	20	1·0428
1	1·0021	21	1·0450
2	1·0042	22	1·0472
3	1·0063	23	1·0494
4	1·0064	24	1·0516
5	1·0084	25	1·0538
6	1·0127	26	1·0561
7	1·0148	27	1·0583
8	1·0169	28	1·0605
9	1·0191	29	1·0627
10	1·0212	30	1·0650
11	1·0233		
12	1·0255		
13	1·0276		
14	1·0298		
15	1·0320		
16	1·0341		
17	1·0363		
18	1·0385		
19	1·0407		

Thus, for example: If we have a resistance of 7 ohms at zero, what would it be at 60 Fahr.? Knowing that zero equals 32 F°, and we wish to find the resistance at 60, there is a difference of 28 deg. between these limits. Multiplying 7 by 1·0605, which is our constant for 28 deg., we have the resistance, $7 \times 1{\cdot}0605 = 7{\cdot}4235$ ohms., which is our answer.

SPRAGUE'S ELECTRIC METER.

The new instruments invented by Mr. Sprague for the purpose of recording the quantity of electricity passing through a circuit are improved applications of the same original principles patented by him in 1878, and which Mr. Edison re-invented in his vebermeter in 1880. These principles, as set forth in the patent of 1878, are "the production of motion in a set of wheels by the agency of plates of metals alternately dissolved and deposited on;" the change of direction of the current being antomatically effected by the weight of metal passed from one plate to the other.

In the original apparatus the electrodes were "suspended by spiral springs, or in any equivalent manner, which will permit them to descend and rise according to their relative weights," while in Mr. Edison's instrument a balance beam was used and spiral springs suggested as an alternative. When the unit weight of metal was deposited, it brought the electrode down so far as to close a contact, by means of which a reversing commutator was actuated, the polar relations of the plates reversed, and at the same time a recording train moved forward one step.

It is evident that these principles permit of an indefinite number of forms of construction, and the new instrument appears to reduce the construction to the utmost limits of simplicity. In fact, all supporting agency is done away with. The moving electrode is simply made to float in the liquid, connection being made to it by a tube containing mercury in which a wire dips, so that the only resistance to motion is the viscosity of the mercury and of the liquids in the cell. The weight of the electrode itself has no longer to be supported, and the metal, as it deposits, merely alters the specific gravity of the electrode, which acts like a hydrometer, and when this addition has sunk it to the defined level, the circuit of the reverser is closed, the metal re-dissolves, the electrode rises to its upper limit, again actuates the reverser and so continues the process *ad libitum*. The electrode and actual deposit may represent only a defined portion of the current, but forms of the instrument are arranged with very large surface, and reversing commutators are constructed of such design as to allow the whole of a large current to pass if desired.

Various subsidiary arrangements are made to meet the various difficulties of applying electrolytic actions to the purpose of electric measurement. As liquids and metals vary in opposite directions in the change of resistance caused by varying temperatures, and as a consequence the relations of shunt circuits will not be constant, a new system is devised by which the metre circuit, consisting of liquid and metal, is compensated by shunt circuits of carbon and German silver, so combined that the variation in resistance by change of temperature is alike in both, and the shunt ratio is therefore preserved unchanged either by external temperature, or by the action of the current itself.

In order to prevent stoppage of the action by freezing of the liquid, a heater is constructed of two glass tubes placed vertically in the liquid, and enclosing between them a wire, which, being heated by the current, warms the liquid. The same appliance is used, if necessary, to produce circulation in the liquid and prevent a dense solution forming at the bottom of the vessel. This is effected by the convection currents set up by the warm surface of the tubes. For warming purposes this heater is actuated automatically by a thermo-regulator, the form preferred being an air thermometer containing mercury and conductor so adjusted that they close the circuit to the heater at an exact limited temperature and open it when that degree is exceeded.

It is singular that Mr. Edison and Mr. Sprague have on several occasions worked out the same idea. To say nothing of the vebermeter, they both patented in 1878, within a few days of each other, an almost identical project for constructing electric lamps, which we noticed at the time. Now again Mr. Edison has patented some improvements in electrometers, one of the claims in which is "The method of maintaining the solution of an electrolytic cell above the freezing point, consisting in heating the same from a carbon or other resistance the circuit of which is made or broken automatically by the fall and rise of temperature." This patent dates seven days later than that of Mr. Sprague. They have also both endeavoured to meet the effects of varying temperature. Mr. Edison balances the liquid and metallic resistances so as to obtain a uniform total resistance in the direct metre circuit. Mr. Sprague adjusts the shunt circuit to vary in proportion with the meter circuit. The effect, of course, is that the proportionality remains constant, and the desired purpose is attained, which is not the case by making the meter circuit a constant resistance united to a shunt circuit, which varies.

Unless in practice there arise difficulties in its application, it would appear that some form of electrolytic decomposition offers the best mode of measuring currents, because this effect of electricity is the only one which is absolute and independent of varying external conditions. The magnetic actions of currents which may be applied for purposes of recording, as they have long been for purposes of indicating currents passing, have not this advantage, as varying friction and metallic expansion must necessarily affect the value of motions generated under magnetic influences, while within very close limits an electric current of a unit value will always effect the same quantity of electrolysis, and as in this meter those actions only are employed which do not absorb energy and set up approving forces there is every reason to expect that it will do its work effectively.

One mode of construction is adapted to use in electrometallurgy. An index is connected with the moving electrode, and traverses a scale graduated to represent the required work, such as ounces of silver or gold. A movable stop is placed at the required position upon the scale, and when the desired quantity of work is accomplished (say the deposit of a given number of ounces of silver in a depositing vat, or a fixed weight of gold upon some large object), the index touches the stop, and thereby closes the circuit, either of a bell to call the attention of the workmen, or of a contact maker, which would cut the work out of the circuit and prevent further deposit. A similar but simpler form is arranged for experimental purposes to act as a voltameter, and enable an observer to watch the action going on in an electric circuit.

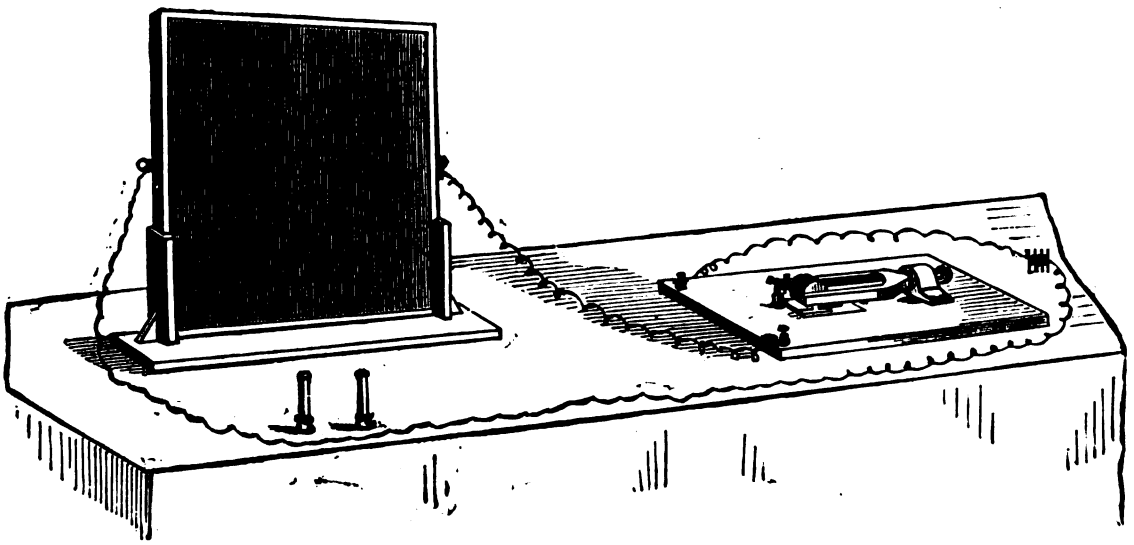
THE INDUCTOPHONE.

We herewith illustrate the apparatus with which Mr. Willoughby Smith has obtained such startling results. We say startling, because although easy of explanation now they are shown, they have not been foreshadowed by any one who has been experimenting in telephony. The apparatus consists of a tuning fork used to obviate the constant presence of an assistant, between the prongs of which is a small electro magnet, and carrying on one prong a small contact piece which makes and breaks contact with a disc carried by the binding screw, shown at the end of the fork. There is another binding screw between the prongs. The connections between the binding screws are underneath the base board. A small battery of Lechanché cells is used. The current is arranged so as to have a make-and-break contact in the main circuit. The frame, which looks like a large looking-glass frame, carries a large flat disc coil of fine insulated wire. This disc coil, when the current goes through it, may be looked upon as a very short magnet, with lines of force radiating from its poles in the manner and directions so well known in connection with magnetism. Hitherto there has been found no substance that will insulate these lines of force. They pass through air, through brick walls, glass, gutta percha, the human body, &c., with equal facility. It is well known that if a piece of iron, steel, &c., be brought within the influence of these lines of force, that is if brought within the field of force, it undergoes a change, and presents phenomena that were previously dormant. Mr. Willoughby Smith found that by bringing the tympanum of an ordinary Bell telephone in the field of force obtained as described, the iron reproduced the sound of the vibrating fork. The results are intensified if the magnet and tympan of the telephone are used in conjunction, the coil being disregarded, it being found to add little or nothing to the phenomena. If a thin disc of ferrotype iron is taken, like the tympan of the telephone, and placed so that the surface of the disc is parallel to the direction of the lines of force, that is, so that no lines of force impinge on the disc, then no sounds are heard; but if the disc is bent so as to cut some of the lines of force, the sound immediately becomes audible. As we have before mentioned, there is no metallic connection between the distributing disc and the telephone disc. The latter may be in the same or another room, and the effects are still obtained. Of course the farther off from the centre of the distributing disc the less intense are the results, as we take the usual law to hold good, and that the influence varies as the square of the distance. The distance to which the lines of force extend has, as yet, not been ascertained. These experiments of Mr. Willoughby Smith prove that the receiving telephone may be altogether independent of the circuit of the sending instrument, so far as regards visible and material connections. All these discoveries point out that

> "There are more things in heaven and earth, Horatio,
> Than are dreamt of in your philosophy."



Willoughby Smith's Inductophone.

THE ELECTRIC LIGHTING BILL.

The Select Committee of the House of Commons appointed to consider the merits of the various measures promoted this Session by gas companies, corporations, and electric lighting companies for the establishment of electric lighting have given their decision in the following resolutions:—

"1. That the Board of Trade be empowered to grant licenses to local authorities, or to private undertakers, with the consent of such local authorities, to supply electricity within a defined area.

"2. That such licenses be for any period not exceeding five years, but may, at the expiration of the license, be renewable with such consent as aforesaid.

"3. That the Board of Trade be empowered to grant provisional orders to local authorities, or to private undertakers, without the consent of such local authorities, for the supply of electricity; but such provisional orders shall be subject to confirmation by Parliament.

"4. That notice of any application for a license or provisional order be given by public advertisement in the district, and full opportunity be given to all parties interested to state their case to the Board of Trade.

"5. That no application for a license or provisional order be granted until the expiration of three months from the notice of such application.

"6. That no application by any local authority for a provisional order under this Act be proceeded with until it has been submitted to a meeting of the local authority, specially summoned for the purpose by public notice.

"7. That licenses and provisional orders should carry with them power to break up the streets for the purpose of laying the necessary wires.

"8. That, where it has been proved to the satisfaction of the Board of Trade that any area as defined by license or provisional order is sufficiently supplied with electric light, and that the supply of gas in such area has ceased to be remunerative, the Board of Trade be empowered to make an order relieving, either wholly or in part, any corporation or gas authority from being compelled to supply gas within such area.

"9. That local authorities be empowered to purchase compulsorily the undertaking of any company or person authorised by provisional order to supply electricity at the end of 15 years, or at the end of any subsequent period of five years.

Digitized by Google

"10. That for the purpose of the purchase of the undertaking, the value of the land, buildings, works, materials, and plant shall be deemed to be their fair market value at the time of the purchase, due regard being had to their nature and their condition, to their state of repair, to their suitability to the purposes of the undertaking, and where a part only of the undertaking is purchased, to any loss occasioned by severance, but without any addition in respect of compulsory purchase, or of goodwill, or of any past or future profits, or of any similar consideration.

"11. That licenses and provisional orders should contain such regulations—(*a*) For securing the safety of the public from injury to life, or from fire; (*b*) for inspection; (*c*) for securing a regular and efficient supply of electricity; (*d*) for fair prices—as experience may prove to be necessary; and where it has been proved to the Board of Trade that public safety is likely to be endangered, they shall at all times have power to make such further regulation as may be required for securing the safety of the public.

"12. That overhead wires be forbidden without the consent of the local authority; and where it has been proved to the satisfaction of two justices of the peace or corresponding authority that any such wire is or is likely to become dangerous to the public safety, they may make an order directing it to be removed upon such terms as they may think fit.

"13. That local authorities supplying the electric light be required to keep separate accounts of such undertaking, and to publish them in detail for the information of the ratepayers.

"14. That the Board of Trade be required to submit to Parliament an annual report of their proceedings under this Act.

"15. That any undertakings which may be authorised by private Acts for the supply of electricity be subject to the conditions contained in this Act."

The committee stands adjourned until the 8th of June, when they will receive and consider amendments not contravening the principles of the resolutions at which they have arrived.

REGULATIONS FOR CABLE SHIPS AT SEA.

In reply to the representations of the telegraph companies that there should be some distinctive signals to distinguish vessels engaged in cable work from vessels "not under control," the signals in the Board of Trade regulations having hitherto been the same for both classes of vessels, and having led to danger and inconvenience, the Board of Trade have forwarded to Mr. Pender, M.P., for the information of the companies, "copies of the new Articles 5 and 27, which it is proposed to include in the revised regulations for preventing collisions at sea." They are as follow:—

"Regulations for Preventing Collisions at Sea.

"Art. 5. (*a*) A ship, whether a steamship or a sailing ship, which from any accident is not under command, shall at night carry, in the same position as the white light which steamships are required to carry, and, if a steamship, in place of that light, three red lights in globular lanterns, each not less than ten inches in diameter, in a vertical line, one over the other, not less than three feet apart; and shall by day carry, in a vertical line, one over the other, not less than three feet apart, in front of but not lower than her foremast head, three black balls or shapes, each two feet in diameter.

"(*b*) A ship, whether a steamship or a sailing ship, employed in laying or in picking up a telegraph cable shall at night carry in the same position as the white light which steamships are required to carry, and if a steamship, in place of that light, three lights in globular lanterns, each not less than ten inches in diameter, in a vertical line over one another, not less than three feet apart; the highest and lowest of these lights shall be red, and the middle light shall be white, and they shall be of such a character that the red lights shall be visible at the same distance as the white light. By day she shall carry in a vertical line one over the other, not less than three feet apart, in front of but not lower than her foremast head, three shapes not less than two feet in diameter, of which the top and bottom shall be globular in shape and red in colour, and the middle one diamond in shape and white.

"(*c*) The ships referred to in this article, when not making any way through the water, shall not carry the side lights, but when making way shall carry them.

"(*d*) The lights and shapes required to be shown by this article are to be taken by other ships as signals that the ship showing them is not under command, and cannot, therefore, get out of the way. The signals to be made by ships in distress and requiring assistance are contained in Article 27.

"Signals of Distress.

"Art. 27. Every ship which is in distress and requires assistance shall make use of the signals named in this article.

"In the day-time.—The following signals, numbered 1, 2, and 3, when used, displayed together or separately, shall be deemed to be signals of distress:—

"1. A gun fired at intervals of about a minute;

"2. The International Code signal of distress indicated by N.C;

"3. The distant signal, consisting of a square flag, having either above or below it a ball, or anything resembling a ball.

"At night.—The following signals, numbered 1, 2, 3, when used or displayed together or separately, shall be deemed to be signals of distress.

"1. A gun fired at intervals of about a minute;

"2. Flames on the ship (as from a burning tar barrel, oil barrel, &c.).

"Rockets or shells, throwing stars of any colour or description, fired one at a time, at short intervals."

THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

Thursday, May 25.

The President having made an announcement with reference to the offer of prizes for papers read before this society—the particulars of which will be found in another column—Lieut. P. Cardew, R.E., described a new method devised by him of determining large electric currents and very low resistances. Several kinds of apparatus constructed by Lieut. Cardew were exhibited and fully explained, with the results obtained in various experiments to test their efficiency. The main object was to get over the uncertainties attending the use of a standard cell, and this was attained by a modification of, or rather an addition to, the Obach galvanometer, two coils being used in a manner somewhat resembling that suggested at a recent meeting by Professors Ayrton and Perry.

Lieut. Arthur W. Bagnold, R.E., then gave an interesting account of the shipment and operations of the field telegraph corps employed in the Transvaal during the year 1881. The paper chiefly dealt with the restoration and maintenance of the line between Newcastle and Pretoria.

Commenting on Lieut. Cardew's paper, Professor Ayrton said: I have been much interested in the communication which Lieut. Cardew has been so kind as to give us, the more so because Lieut. Cardew has been travelling along some of the lines traversed by Professor Perry and myself in the construction of simple instruments for measuring strong currents and small resistances. When attempting in 1879 to employ the two-coil method for measuring currents, which Lieut. Cardew has more recently adopted, we came to the following difficulty, which I fear Lieut. Cardew will find it not easy to overcome, and it is this. As long as you trust to the weak earth's field to control your suspended needle it is easy enough to have many turns of the fine wire coil close to your suspended magnet, and one or two convolutions of the thick coil farther away, but if to make the instrument dead beat a powerful permanent magnetic field be attached to the instrument, it requires several convolutions of the thick wire traversed by the strong current to be put close to the suspended magnet to produce a deflection, and in that case you cannot approach the fine wire near enough to the magnet for the weaker current to equalise the action of the stronger. We, therefore, abandoned this method, which has been followed by Lieut.

Digitized by Google

Cardew, and instead used in our ammeters, as the members are aware, the very same convolutions of wire for the thick coil, and for the thin, the position of the commutator determining the mode of connecting up the wires. Lieut. Cardew's galvanometer for measuring currents is obviously intended rather as a laboratory instrument than as a portable one to be used anywhere, since a new, well made Daniell cell, necessary to be used with it each time a measurement is made cannot be found at an electric light installation, and to carry a large cell such as is on the table about with one would be troublesome. His instrument for measuring small resistances has the same object as the ohmmeter of Professor Perry and myself, but fulfils its object in a different way. He makes the difference between E and C equal to nought, where E is the electromotive force between the two ends of that portion of the circuit of which it is desired to measure the resistance, and C the current in the main circuit, while he measures the actual ratio of E to C or the resistance directly by using not only two coils parallel to one another, but at right angles to one another. With the differential galvanometer of his a balance method is alone possible, for otherwise the zero of his instrument would vary with the strength of the current flowing in the main circuit, and the calibration of such an instrument would be impossible. It appears to me that zero instruments, although they possess considerable sensibility, are unsuitable for quick rough work, since quick changes cannot be measured by them, and I therefore prefer dead beat instruments like our own in which the pointer points to the answer at once, without the necessity of adjusting a screw, or otherwise obtaining balance each time a measurement is made. But I have no doubt that in the laboratory Lieutenant Cardew will obtain most valuable results with his instruments, as they certainly show that he possesses both originality and ingenuity in designing measuring instruments of this class.

With this meeting the session closed.

THE GREAT WESTERN ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on Tuesday, the 30th ult., for the purpose of considering the propriety of, and, if thought expedient, to expunge Article 40, and the words "or the person entitled to the share by transmission, as the case may be," in Article No. 41, from the Articles of Association.

The undermentioned are copies of Section 40 and 41 of the existing articles:—

Article 40.—"Where any person entitled to a share by transmission, and not having entitled himself according to these presents, either to be registered himself as the holder thereof, or to have his nominee registered, fails for three months after being thereunto required by notice from the directors so to entitle himself, such share may at any time after the expiration of that period be forfeited by a resolution of the directors to that effect."

Article 41.—"When any share has been forfeited in accordance with these presents, notice of the forfeiture shall forthwith be given to the holder of the share, or the person entitled to the share, by transmission, as the case may be, and an entry of such notice having been given, and of the forfeiture with the date thereof, shall forthwith be made in the register of members opposite to the share; but the provisions of this article are directory only, and no forfeiture shall be in any manner invalidated by any omission or neglect to give such notice, or to make such entry as aforesaid."

Mr. H. Russell Evans having been voted to the chair,

The Secretary (Mr. John Parsons) read the notice convening the meeting as above,

The Chairman then said: Gentlemen, you have all had notice of this special meeeing. As you are aware, we have called it for the purpose of complying with the requirements of the Stock Exchange before we get a settlement and quotation for our shares. It was the practice, I believe, in times past to give an undertaking on the part of the solicitor to expunge what the Stock Exchange considered objectionable in the Articles, but for some reason or other they have altered their ruling in that respect, and they now require a meeting absolutely called before they grant a settlement and quotation. He concluded by moving a resolution expunging Article 40 from the Articles of Association of the Company, and afterwards observed: The resolution is merely technical, as you see, to comply with the requirements of the Stock Exchange.

Mr. Stenger (shareholder) formally seconded the resolution, which was carried unanimously.

The Chairman next moved the expunging of the words mentioned from Article 41.

Mr. Simons seconded the motion.

The Chairman put it and declared it carried unanimously, and announced that a further meeting would be necessary to confirm the resolutions.

Mr. Simons inquired if any concessions had been given to any other parties by the Company.

The Chairman: We have sold Devon and Cornwall, and have important negotiations pending for the sale of some other portions of our district which, if carried out, will lead to a very large profit to our shareholders.

A vote of thanks to the chairman closed the proceedings.

BRUSH MIDLAND ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of the members of the above Company was held at the Terminus Hotel, Cannon-street, on the 1st inst., at which the following resolutions were considered:—

1. That the Articles of Association of the above Company be amended by striking out the fortieth Article.

2. That the Article of Association of the above Company numbered forty-one, be amended by striking out the following words in the third and fourth lines of the said Article, namely:—"or the person entitled to the share by transmission as the case may be."

3. That the Article of Association of the above Company numbered 112, be amended by striking out the words "or otherwise interested" occurring in the fifth line of the said Article.

Mr. James Whitehead presided.

The Secretary (Mr. H. N. Myers) having read the notice convening the meeting,

The Chairman said: Gentlemen, the meeting to-day is of a formal character. It is known to most of you, I daresay, that before you can obtain a settlement and quotation on the Stock Exchange the committee of that body go very carefully through the Articles of Association on behalf of shareholders and the public who are interested in any given company. They have done so in the case of this Company, and there are two Articles to which they took exception. I may say that the exception they took to them met entirely with the approbation of the whole of the directors of this Company, and in accordance with the suggestion made to us, and made entirely in concurrence with the opinion of our legal advisers, we recommend the shareholders to-day to pass resolutions with the view of carrying out the alterations suggested. It is unnecessary for me, I think, to detain you at any length by any explanation, because it is quite clear on the face of it what the object of the alterations is. He concluded by moving the first resolution as above mentioned.

Mr. John Parsons seconded the motion, and it was carried unanimously.

On the motion of the Chairman, seconded by Mr. Jolin, the second resolution was passed; and the third resolution was passed on the motion of the Chairman, seconded by Mr. Richard Glyn.

A vote of thanks to the Chairman terminated the proceedings.

RECENT INVENTIONS.

ABSTRACTS OF SPECIFICATIONS.

2484. NEUTRALISATION OF CURRENTS IN TELEGRAPH AND TELEPHONE LINES, *W. P. Thompson, Liverpool.—June 8th*, 1881.—(*A communication from F. V. Rysselberghe, Brussels.*)—(*Not proceeded with.*) 2*d.*

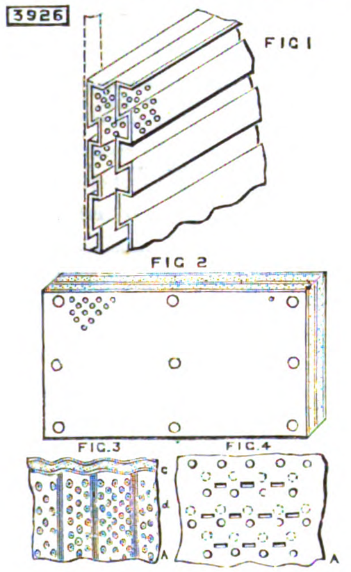
The reception coils are made of enormous resistance compared with the line, hence, the inventor states, the inductive currents will be practically neutralised.

2592. IMPROVEMENTS IN THE MANUFACTURE OF TELEGRAPHIC OR TELEPHONIC CONDUCTORS, &c., *W. R. Lake, London.—14th June*, 1881.—(*A communication from H. A. Clark, Boston, U.S.A.*) 6*d.*

This invention relates to a machine adapted for coating wires with insulating material, which is so constructed that the material is forced through the die opening as the wire proceeds through the same, giving direction to the coating material in the line along which it passes through the die, opening before it reaches the wire it is to coat. It is thus prevented from working itself in a backward direction upon the wire. This, it is claimed, is an advantage where the wire may have previously been coated. The invention also relates to a compound cable for telephonic or other purposes, in which the wires are all at the same distance from and parallel with each other.

3926. SECONDARY BATTERIES OR MAGAZINES OF ELECTRICITY, *J. S. Sellon.—10th September*, 1881. 6*d.*

The electrodes are of lead or other suitable material, which are, or may be, coated with, or have attached to, or packed therein, spongy, precipitated, or reduced lead, &c. The lead electrodes are perforated, serrated, grooved, or corrugated, and the claim is the construction of secondary batteries of perforated plates or sheets, roughened, serrated, or indented, composed of lead, platinum, or carbon, upon, in, or against which plates spongy or finely divided lead or oxides, or other salts or compounds of lead, or other suitable substances or compounds, are, or may be, held. The figures show some forms adopted.



2612. IMPROVEMENTS IN THE CONSTRUCTION OF ELECTRIC LAMPS AND APPARATUS FOR ELECTRIC LIGHTING, *W. Crookes.—15th June*, 1881. 4*d.*

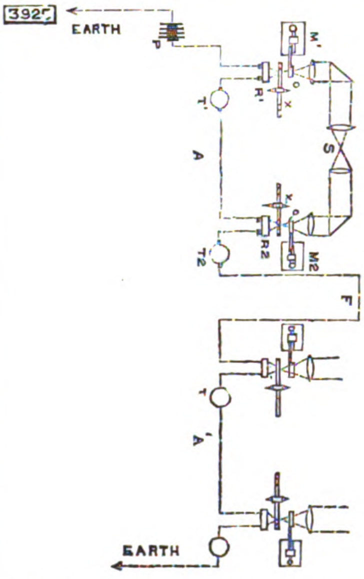
After purifying the material to form the carbon filament from silica, it is treated with cuprammonia to destroy its structure. The copper is afterwards extracted. Modified methods are described.

2658. APPARATUS FOR SAVING LIFE AND PROPERTY AT SEA, *A. D. Roth, Blackheath.—17th June*, 1881. 6*d.*

This consists in the general construction of a safety and signal buoy; secondly, in coating such buoys with luminous paint and fitting them with lights and light-reflecting signals in combination with another mode of signalling, and the adaptation of electric action for the purpose of sight and sound signalling on such buoys.

3929. AN IMPROVED SYSTEM OF MULTIPLEX AND SELF-REVERTABLE "TELERADIOPHONE," *E. J. P. Mercadier, Paris.—10th September*, 1881. 10*d.*

This invention refers to a system of telegraphing, in which the signals are produced by radiophonic effects. The figure shows two stations A and A¹ separated by a long line F, in which two sets of transmitting and receiving apparatus are arranged. A continuous current from battery P passes successively from station A, through radiophonic receiver and telephone R^1 T^1, to R^2 and T^2, &c., by line F. In front of each receiver, made of selenium, lamp-black, &c., are situated the openings of a wheel, rotating rapidly and continuously round an axis X. A diaphragm O of the same size as opening in



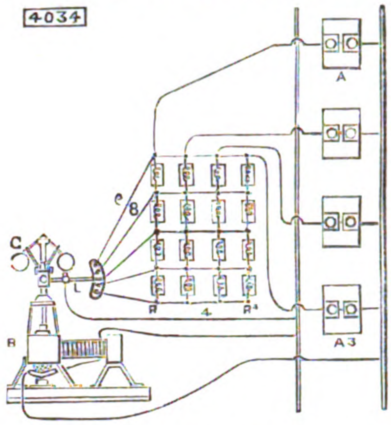
wheel is fixed to a rigid shaft forming a prolongation of key lever M^1, and when at rest closes the openings, thereby checking the radiations from source S. The movement of M^1 consequently alternately allows and prevents the passage of radiations to selenium receiver R^1, and produces variations in its resistance, and therefore in the intensity of the current passing through said receiver. There is, therefore, produced in all the telephones T^1, &c., a musical sound, the pitch of which is determined by the rate of turning of the wheel opposite the respective receivers. It is thus possible to transmit Morse signals acoustically. The figure shows the various arrangements of lenses and specula for conveying the light from source S to the receivers. Various modifications of the above with details of the apparatus are described and illustrated in the specification.

4057. IMPROVEMENTS IN THE PRODUCTION AND EMPLOYMENT OF CONTINUOUS ELECTRIC CURRENTS IN RAILWAY CARRIAGES, &c., AND IN APPARATUS USED THEREFOR, &c., *H. E. Newton, London.—20th September*, 1881.—(*A communication from the Société Universelle d'Electricité Tommasi, Paris.*) 6*d.*

This consists in the combination of a dynamo-machine driven by belting from the axle of the carriage in which it is placed, with a secondary battery, an interrupter, and electric lamps, in such a way that a continuous current shall be supplied to the lamps even though the train be at a standstill, and, consequently, the dynamo-machine also.

4034. IMPROVEMENTS IN AND CONNECTED WITH DYNAMO OR MAGNETO-ELECTRIC MACHINES AND ELECTRO-MOTORS, *P. Jensen, London. 19th September*, 1881.—(*A communication from T. A. Edison, Menlo Park, New Jersey. U.S.*) 6*d.*

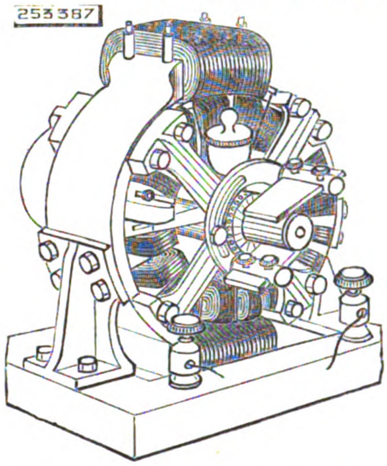
The object of this invention is to regulate the generating capacity of dynamo machines. One method of doing this is shown in the figure. A to A^3 are Edison machines connected in multiple arc; B is an electric engine in a shunt circuit. Upon the shaft of its armature is a governor, G, to which is connected switch lever, L. The speed of armature and governor depends upon the current in the shunt and main circuit. If the current is too little the speed falls, governor balls



drop, moving L into contact with 8 or 9, cutting them out of circuit, and causing an increased current through the field coils, and consequent increase of generative capacity. R to R^3 are resistance boxes.

253,387. DYNAMO-ELECTRIC MACHINE, *Chas. A. Hussey New York N.Y., assignor to the Hussey Electric Company, same place.—Filed August 13th*, 1880.

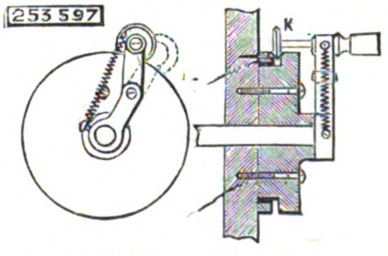
Brief.—The field magnet is circular, inclosing the armature, and has the portion upon which the



wire is wound offset, so that the inner surface of the coil is flush with the inner surface of the polar portions.

253,597. TELEPHONE SIGNAL GENERATOR, *James F. Gilleland, Indianapolis, Ind., Assignor to the Gilleland Electric Manufacturing Company, same place.—Filed January 3d*, 1881.

Claim.—(1) The combination of two insulated contact plates, with an extensible spring-retracted crank carrying a contact plug, substantially as specified. (2) The combination, in a magneto-electric machine, of a crank consisting of arms pivotted together, a contact piece carried by the outer arm, and a retractible spring, whereby the shunt circuit is closed when the crank is at rest,



and opened and held open automically when power is applied to turn the crank. (3) The combination of an extensible spring-retracted crank, with metallic disc K, and insulated contact plates so placed as to form a groove, in which said disc is held by the spring when the crank is at rest, so as to close the shunt circuit around the armature, said disc, when power is applied to the crank, being lifted from the groove, so as to open and hold open the shunt.

THE

SCHOOL OF TELEGRAPHY & ELECTRICAL ENGINEERING.

ESTABLISHED IN 1868.

12, PRINCES STREET, CORNER OF HANOVER SQUARE, LONDON, W.

(Removed from 4, George Street, Hanover Square.)

MANAGING DIRECTOR: Mr. T. J. JONES, M.S.T.E.

The course of Practical and Theoretical Instruction in the higher branches of Overland and Submarine Telegraphy embraces, in addition to the manipulation of he various systems of working in general use, the following subjects:—

MATHEMATICS, MECHANICS, and CHEMISTRY. } In relation to Telegraphy.	SIGNALLING and TESTING INSTRUMENTS.	ELECTRO-STATICS.	METHODS of TESTING the ELECTRICAL CONDITION of a LINE During and After its Construction.
	ENGINEERING FORMULÆ and their Application in Practice.	ELECTRO-DYNAMICS.	TESTING FOR and LOCALISING FAULTS, &c., &c., &c.
		MAGNETISM.	

The instruction, both in signalling and testing, is of a thoroughly practical character, as the classes work with the actual instruments used on long lines, through cables of various lengths, from 600 to 3,000 knots, so that the signals of the Eastern, Atlantic, and Brazilian Co.'s, &c., are exactly reproduced, and the pupils fitted for any line.

A complete practical and theoretical course of instruction on the TELEPHONE and the ELECTRIC LIGHT, and their commercial utilisation, has now been added to, and embodied in, the ordinary curriculum, as the advantage of being associated with any great commercial application of science at an early period of its development is one which has been so often exemplified that it can scarcely fail to be appreciated by those who have in view professional success.

That **TELEPHONIC** communication and **ELECTRIC LIGHTING** constitute such applications is sufficiently shown by their rapidly increasing progress; and therefore no pains or expense have been spared to place at the disposal of the pupils the technical and scientific instruction requisite to qualify candidates for the most important posts in connection with these new branches of electrical engineering. In order that the instruction in the erection, adjustment, testing, and working of **TELEPHONE** and **ELECTRIC LIGHT** circuits may also be thoroughly practical, complete working telephone exchanges upon the various systems in use in different countries have been fitted up; every kind of telephone, for both exchange systems and private lines, with all apparatus used therewith, is provided (in duplicate when possible, so that students may be able to dissect and reconstruct the same). The necessary tools and materials are available, and every facility is given for conducting experiments by the pupils desirous of so doing, and a similar course is being pursued with the **VARIOUS LAMPS** and **MACHINES, &c.,** in the **ELECTRIC LIGHT** Department, so that pupils from the School are in a position to enter either of these new fields.

The complete Practical and Theoretical course extends over a period of Six Months.

Arrangements have been made so that Inventors, Amateurs, and others can now have every facility, with all necessary apparatus provided in private rooms, to compare, test, or perfect any Inventions, Apparatus, &c., connected with Telegraphy, Telephony, and the Electric Light. Financial and the highest profession' assistance can also be had.

Further particulars may be obtained on application to W. N. TIDDY, *Secretary.*

THE EXCHANGE TELEGRAPH COMPANY, LIMITED.

Head Offices--17 & 18, Cornhill, E.C.; Stock Exchange, E.C.; 27, Regent Street, W.

Incorporated the 28th March, 1872, under the Companies Acts of 1862 and 1867, and by Special License from H.M. Postmaster-General.

This Company will undertake to supply recording instruments, telegraphically connected with the Stock Exchange, by the aid of which Subscribers, at their respective offices, may be kept continuously advised throughout the day of the constantly occurring market fluctuations in stocks and shares.

Instruments are placed in the offices of Subscribers and kept in order by the Company, free of every expense but that of rent, and inspectors visit them daily to supply ink and paper.

Terms: £50 per annum, payable quarterly in advance.

Applications for instruments to be made to the Secretary at the above address.

Not having any springs or clockwork to wind up or to depend on, these instruments are acknowledged by those familiar with the system of telegraphy to be the only instruments yet invented that are capable of doing the work required of them continuously for a lengthened period, as evidenced by the fact that the Gold and Stock Company of New York, having the monopoly of this kind of business in the States, and which owns all the patents of the day of any value, has, after due trial, discarded all others.

The Company is prepared to treat with provincial Companies requiring instruments for the delivery of news for either single or double wire systems under the Company's patents, whereby from central stations identical information can be simultaneously delivered to any number of recipients by automatic, self-adjusting, printing instruments requiring no local batteries, no winding up, and no knowledge of telegraphy on the part of the receiver, the printing being in bold roman type, and the propulsion of the paper being effected by the electricity supplied from the Central Office.

The instruments supplied by the Company can be had to work either on single or double wires, and to print either on a slip or tape of paper, as has hitherto been the custom, or on a broad band of paper in column form.

THE NEW MATERIAL

For ENGINEERS (Sanitary and Hydraulic), ELECTRICIANS, AXLE MAKERS, BRASSFOUNDERS, PUMP MAKERS, RAILWAY COMPANIES, CARRIAGE and WAGGON BUILDERS, &c.

SUBSTITUTE FOR LEATHER, RUBBER, AND PERCHA.

It is unequalled for Washers of all kinds, Hot and Cold Water Packings and Plumbers' uses generally, Insulators, &c.

THE PATENT VULCANISED FIBRE

Is supplied in Sheets from 1-32in. to 1in. in thickness, and in two qualities: Flexible, 2s. per lb.; Hard, 2s. 3d. per lb.

MOSSES & MITCHELL, 62, QUEEN VICTORIA STREET, LONDON.

VESTRY of ST. GILES, CAMBERWELL.—To ELECTRIC LIGHT COMPANIES and OTHERS.—The General Purposes Committee of the above Vestry will meet at the Vestry Hall, Peckham-road, on MONDAY, the 12th June prox, to receive TENDERS for LIGHTING by means of ELECTRICITY as an experiment.

Tenders to be in accordance with Specification and conditions to be obtained at the Surveyor's Office, Vestry Hall, on and after WEDNESDAY, the 31st inst.

Tenders must be sealed and endorsed "Tender for Electric Lighting," to be delivered at the Vestry Hall not later than 5 o'clock on the 12th of June aforesaid.

The Vestry does not bind itself to accept the lowest or any Tender.

By order,

GEO. W. MARSDEN, Vestry Clerk.

Vestry Hall, Camberwell, 26th May, 1882.

WANTED, a thoroughly practical ELECTRICIAN, or ENGINEER well up in electricity, to undertake the management and development of an Electric Lighting Department with a Company who are in possession of certain patents for electric lamps. Address, by letter, 411, Oxford-street, W.

TO ELECTRIC LIGHT COMPANIES and Others.—To LET, a large and splendidly lighted lofty BASEMENT and GROUND FLOOR as warehouse or factory and offices. Corner building in important thoroughfares. Two entrances. Superficial area about 3,600 feet. Steam power can be borrowed at a moderate cost. Rent, including rates and taxes (only) £250.—Apply to Mr. T. HYDE, Hatton Garden Steam Works (near Clerkenwell-road), E.C.

TO ELECTRIC LIGHT COMPANIES.—A Mem. Inst. C.E. having over 20 years' experience in public works, and nearly three years in electrical operations with the dynamo machine, desires EMPLOYMENT. Ample references.

Address, C., office of this Paper.

ELECTRICIANS desiring FINANCIAL ASSISTANCE to develop and utilise their discoveries are invited to address E. D. C., care of C. MITCHELL and Co., Advertising Agents, Red Lion-court, Fleet-street, E.C.

INSULATED ELECTRICAL WIRE, Silk, Cotton, or India-rubber covered. Conductivity guaranteed. German Silver Wires for Resistance. Braided Handle Cord, Silk Cord for Electric Bells, &c.—WILLIAM RICKARD, Derby. London Agent (stock kept), EDWIN HOLLOWAY, 2, Gutter-lane, E.C.

LIFE ASSOCIATION of SCOTLAND.

Founded 1838.

HEALTHY PERSONS OF ALL AGES will find in the BONUS SYSTEMS of the LIFE ASSOCIATION of SCOTLAND advantages far exceeding those which can be obtained under any of the ordinary systems.

Claims and Bonuses paid £4,028,000

Annual Revenue 436,000

Immediate Entrants in Class A will secure ONE YEAR'S BONUS MORE THAN LATER ASSURERS in that class.

LONDON—5, Lombard-street, and 48, Pall Mall.

EDINBURGH—82, Princes-street.

SLIP

Brazilian Submarine Telegraph Company. — The traffic receipts of this company, for the week ended 2nd June, amounted to £3,390.

Brush Midland Electric Light Company. — Mr. Martin Fradd has been appointed manager of this company, and Mr. Vyle chief electrician.

Electric Railway at the Crystal Palace.—We believe that an electric railway is shortly to be constructed in the grounds of the Crystal Palace.

Telegrams for China.—The Amoy-Shanghai cable being restored telegrams for Shanghai are accepted as usual for transmission by the Eastern Telegraph Company.

South Eastern and Provincial Brush Electric Light Companies.—Mr. Joseph S. Beeman, A.M.I.C.E., M.S.T.E., has been appointed engineer and electrician to these companies.

Electric Light in Clerkenwell.—At the last meeting of the Clerkenwell Vestry it was stated that arrangements had been made for the electric lighting to be commenced in the parish at Midsummer.

West India and Panama Telegraph Company.—The estimated traffic receipts of this company for the half-month ended May 31 amounted to £3,305, as compared with £2,759 in the corresponding period of 1881.

Eastern Extension Telegraph Company.—The traffic receipts of this company for the month of May, 1882, amounted to £33,087, and to £29,523 for the corresponding period of 1881, being an increase of £3,564.

The Channel Tunnel.—The electric lights hitherto used in the Channel Tunnel works have been abandoned for the present, and ordinary candles returned to, as the engine used as a motor is now employed on other work.

Fire Caused by Lightning.—The Poor House in the small town of Oesthamman, in Sweden, was set on fire by lightning and burnt to the ground on the 1st of June. Out of fifty-two inmates twenty perished in the flames.

Interim Dividend.—The directors of the Brazilian Submarine Telegraph Company (Limited) have declared an interim dividend of 3s. per share, or 6 per cent. per annum, free of income-tax, for the quarter ended March 31 last.

Cable Repaired.—The Great Northern Telegraph Company notify the repair of their Amoy-Shanghai cable, in consequence of which telegrams for all stations in China and Japan are again accepted for transmission by this company's route.

London Platino Brazilian Telegraph Company.—The revenue of this company for the month of February is estimated at £2,194 (Western Brazilian portion £1,563, Land Lines £631), as against £2,010 for the corresponding period of 1881.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of this company during the month of May was 3,408, estimated to produce £3,300, against 2,979 messages, producing £3,021, in the corresponding month of last year.

Telegrams for South America.—The cables between St. Vincent and Pernambuco, between Bahia and Rio de Janeiro, and between Pernambuco and Maranham, are now repaired; and communication is therefore restored with all parts of South America.

The Royal Society of Edinburgh.—The council of this society has awarded the Keith Prize, for the biennial period 1879-81, to Professor Chrystal, for his paper "On the Differential Telephone," published in the society's *Transactions* for the session 1879-80.

The Electric Light and Power Generator Company.—We understand that this company has received instructions to light up the Botanical Gardens with the electric light (Maxim incandescent and Weston arc lights) on the occasion of the annual *fête* on the 22nd of June.

Western and Brazilian Telegraph Company.—The traffic receipts of this company for the five weeks ending 26th May amounted to £8,550, and for the week ending 2nd June, 1882, to £2,441, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited).

Electric Lighting for the City.—The consideration of the tenders sent in for lighting the city for one year from 1st October next, which were invited a few weeks back, and were to be sent in by the 12th May, has been postponed pending the passing of the electric lighting Bill now before Parliament.

Petition for Winding up a Company.—A petition has been presented by the Anglo-American Brush Corporation in the Court of Session, Edinburgh, for the winding up of the Scottish Brush Electric Light and Power Corporation. It is said that the shareholders of the latter company are unanimously opposed to this proceeding.

Metropolitan Brush Electric Light Company.—We understand that Mr. Robert Hammond has agreed to join the Board of the Metropolitan "Brush" Electric Light and Power Company (Limited), a working arrangement having been entered into between that Company and the Hammond Electric Light and Power Supply Company (Limited).

The Charing Cross Electric Railway.—The Bill for this railway, which was declared not to have complied with the standing orders by the Lords' Examiner on a technical point, came before the Lords' Committee on Standing Orders last week. The defect having been remedied by the promoters, the Bill was declared to have complied with the standing orders.

An Electrical Railway at St. Louis.—According to an American contemporary the town of St. Louis is shortly to have an electric railway. It will be half a mile long, and will be constructed in the piece of ground known as the "agricultural field." The railway will be constructed by Mr. Heisler, an electrician of St. Louis, and will be on the same principles as a model exhibited by him at the St. Louis Fair in 1878.

Electric Light at Cardiff.—During last week the exterior of the offices of the *Western Mail* in Cardiff were illuminated by means of nine arc lamps. Two of these were placed on a tall flagstaff on the top of the building, and could be clearly seen from the neighbouring towns of Penarth, Llandaff, &c. The occasion of the illumination was the holding of the Bath and West of England Society's Exhibition in the town.

Central and South American Cable.—The India Rubber, Gutta Percha, and Telegraph Works Company (Limited) have received a telegram from their engineer, Mr. Robert Kaye Gray, on board their steamer "Silvertown,"

Digitized by Google

announcing the completion of the third section, 483 nautical miles in length, of the Central and South American Telegraph Company's cable—namely, that from Santa Elena, in Ecuador, to Buenaventura, in the United States of Colombia.

Electric Light on a Channel Steamer.—The paddle steamer, "Brittany," was launched from Messrs. John Elder and Co.'s Fairfield Works, on the Clyde, last week. She is one of two vessels being constructed by this firm for the London, Brighton, and South Coast, and the Western of France Railway Companies. She will be fitted with every convenience, including electric lights and electric bells. She was christened by Mrs. Knight, wife of Mr. J. P. Knight, well known as the able general manager of the first of the above-named companies.

Electric Light in Salford.—Messrs. Mather and Platt, engineers, of Salford, are now lighting up a portion of their works by means of Edison lamps, and we believe that it is their intention to greatly increase the number now in use. At present the firm have 81 lamps in their workshops and 53 in their offices, or a total of 134 lamps. The current is generated by two dynamos, driven by two single-cylinder engines of 6 h.-p. nominal. In the offices the lights are fitted in special chandeliers, but in the workshops they are attached to the present gas-pipes.

Society of Telegraph Engineers and of Electricians. — The President of this society, Lieut.-Colonel Webber, has issued invitations to the members to visit the School of Military Engineering at Chatham on the 11th of July, permission to do so having been granted by Brigadier-General Sir Evelyn Wood, V.C., G.C.M.G., &c., commanding the Chatham District. A special train will be provided for the convenience of those who may wish to be present by the London, Chatham, and Dover Railway Company, and will leave Victoria at 11:34 a.m., Holborn at 11:32, and Herne Hill at 11:47, returning from Chatham so as to reach London by 7:18 p.m.

Electric Light on Board Ship.—The arrival of the "Ghoorka," a new steamer recently built for the British India Steam Navigation Company by Messrs. Denny, of Dumbarton, at Scapa, in the Orkney Islands, on a pleasure trip, with Mr. Mackinnon, the chairman of the company and others on board, aroused no little excitement amongst the inhabitants of that part of the islands. The vessel is fitted with the electric light, and this was the first time that such means of illumination had been seen by the inhabitants, many of whom availed themselves of the opportunity to visit the vessel. The "Ghoorka" is to leave London on her first voyage to India on the 28th of this month.

Burglars and Electric Bells.—Two men were brought up at the Dale-street police court, Liverpool, last week, charged with breaking into the premises of some timber merchants in Camden-street, on Whit Sunday morning. The premises were, however, fitted with an electric bell, fixed in such a manner that the door could not be opened without ringing the bell, although it was placed too far away for persons entering to hear it sound. The bell gave the alarm, the police were communicated with, and the prisoners caught redhanded. They were committed to the assizes for trial. A few such cases of prompt capture, and burglars may begin to find that other and more honest means of getting a livelihood are preferable.

New Companies.—W. T. Henley's Electric Light and Power Company has been formed to acquire the patents of Mr. W. T. Henley. It has a capital of £100,000.—The Electrical Share Trust (Limited) has been formed with a capital of £500,000 to extend the trust principle to investments in electric light, telegraph, and telephone companies.—The prospectus is issued of the "Standard" (Fyfe-Main) Electric Lighting and Construction Company (Limited), with a capital of £500,000 in £5 shares, of which the first issue is £300,000. The company is formed to acquire the sole right to the "Standard" arc light system of electric lighting for all parts of the world where patents may be obtainable. The price to be paid to the vendors is £70,000 in cash and £100,000 in fully-paid shares.

Time Signalling.—The following information, relating to time signalling in England, is taken from the report of the Astronomer Royal for 1881:—"There has been only one case of accidental failure in the automatic drop of the Greenwich time-ball. On four days the ball was not raised on account of the violence of the wind. The Deal ball has been dropped automatically at 1h. on every day throughout the year, with the exception of 15 days, on which there was either failure in the telegraphic connection or interruption from telegraphic signals continuing up to 1h., and of one day when the current was too weak to release the trigger without the attendant's assistance. On three days high wind made it imprudent to raise the ball. The Westminster clock has continued to perform well, its errors having been under one second on 40 per cent. of the days of observation; between one second and two seconds on 44 per cent.; between two seconds and three seconds on 14 per cent.; and between three seconds and four seconds on 2 per cent. Time signals originating in the Observatory are distributed at 10 a.m. and 1 p.m. to all parts of the country by the Post Office telegraphs."

The Telephone Case.—A circular has been issued in Scotland by the United Telephone Company, stating that in in the case against Alexander MacLean judgment was pronounced by Lord MacLaren sustaining the validity of Bell's and Edison's patents, and that an interdict was granted against MacLean for infringement of both the above patents. The circular then goes on to say:—"We are informed that you are using both a Receiving and Transmitting Instrument, which are infringements of the Patents above referred to, without any license from the United Telephone Company (Limited), or those empowered by them to grant licenses. It is not wished to act harshly towards those who have in ignorance of the Company's rights rendered themselves liable to an action for damages, and we are therefore instructed to inform you that if the Instruments which you use are given up within one week from this date to the Licensees or Agents of the United Telephone Company, viz., the National Telephone Company (Limited) at the address given below, and if, at the same time, the name and address of the person from whom you purchased the Instruments are furnished, no claim for damages will be made against you."

Magnetic Declination.—According to the report of the Astronomer Royal for 1881, just issued, the following are the principal results for magnetic elements for 1881:—Approximate mean westerly declination, 18° 27′; mean horizontal force, 3·915 in English units, 1·805 in metric units; mean dip, 67° 33′ 45″ by nine-inch needles, 67° 34′ 54″ by six-inch needles, and 67° 35′ 5″ by three-inch needles. The magnetic declination for January 1, 1882, was, on the authority of Mr. William Ellis, 18° 25′ west, and the dip 67° 34′. In his report the Astronomer Royal remarks:—"On September 12 and 13 and April 16 and 19 magnetic storms have occurred, the latter being of more marked character than any that have taken place since the great storms of the year 1872, and it is a significant fact that exceptionally large spots

Digitized by Google

made their appearance on the sun shortly before. Smaller magnetic movements are now also much more frequent, exhibiting a marked contrast to their general appearance some two or three years ago. In regard to the long period variation of about 11 years, it can now be stated definitely that the minimum as regards diurnal range of declination occurred at the commencement of 1879, while, as regards diurnal range of horizontal force, it occurred unmistakably earlier, about August, 1878."

THE POSTAL AND TELEGRAPH BENEVOLENT SOCIETY.—The annual meeting of the United Kingdom Postal and Telegraph Services Benevolent Society was held in Manchester on Monday. Delegates were present from London, Birmingham, Leicester, Manchester, Bristol, Leeds, Normanton, Shrewsbury, Rotherham, Huddersfield, Swansea, Liverpool, Crewe, Stafford, Northampton, Oldham, and other towns.—The annual report and balance-sheet showed that during the year a sum of £4,490 had been paid to the nominees of sixty-five members who had died in benefit, making a total of £16,490 since the establishment of the society. During the year 574 new members were enrolled.—Propositions were made by delegates representing offices in different parts of the country with the object of altering the rules so as to bring the benefits of the society within the reach of a larger number of candidates, and a resolution was passed by which members of the postal and telegraph service can insure their lives on more advantageous terms than have yet been available.—A proposition that a levy of 2d. from each member of the society should be made, with the object of creating a fund to enable the Central Secretary to make immediate grants in case of a member's death, was withdrawn, after a statement that no case had arisen requiring such a provision.—The newspaper branch in the London office brought forward a proposition that, with a view to the future stability of the society, it was necessary to establish a guarantee fund, but after a long debate the proposition was rejected. The meeting carried several propositions for revising the rules; and in the evening dined together at the Grosvenor Hotel.

ELECTRIC LIGHT IN THE HOUSE OF ASSEMBLY, CAPE TOWN.—The Cape *Times* of the 11th May says:—"The House of Assembly was publicly lighted for the first time last evening by the electric lighting apparatus which has been fitted up by a representative of Mr. Edison, the celebrated American inventor. The light was tried on the previous evening and the result proved quite satisfactory. At five o'clock yesterday afternoon the light was turned on without any previous warning, and before hon. members recovered from the surprise occasioned by the novel sight, the House was illuminated by the beautifully bright and steady glow of the forty-four lights placed along the walls. There are thirty-four of these lights in the body of the House, and ten in the public gallery. The present experiment has been undertaken by Mr. Edison, at the instance of the Colonial Government, with the view of enabling them to decide whether it is expedient to introduce the electric light into the New Houses of Parliament. The apparatus has been fitted up under the direction of Mr. C. Hortsek, who was specially sent out by Mr. Edison for the purpose. The engine and apparatus are placed in a large shed at the top of the gardens, and are connected with the House by means of an nsulated wire. The engine used is a ten-horse power one, and the generator is known as the Edison A dynamo-machine, calculated to produce current sufficient for 60 sixteen-candle lights. There was a large attendance of the public in the House last evening, and much satisfaction was expressed alike by members and spectators with the effect produced by the bright, soft, and penetrating light." We congratulate Mr. Hortsek on the success which has attended his labours.

UNDERGROUND TELEPHONE WIRES.—According to the *Operator* the American Bell Telephone Company have laid an underground telephone cable along the Boston and Providence Railroad, to ascertain the practicability of such cables for telephone purposes. Our contemporary says:—"The cable was made by Eugene F. Phillips, of Providence, R.I., and consists of 21 rubber-covered copper wires in an external protecting pipe of lead. Ten of these conducting wires, after being insulated with rubber, are covered with tinfoil, which is intended to act as a conducting surface to carry off extraneous induction currents. Ten more, after being covered with rubber, are twisted together, and are intended to be operated as metallic circuits. This plan is also regarded as a protection against induction. The twenty-first wire is an ordinary No. 13 office wire, covered with cotton and paraffined. The cable when completed weighed 30 tons, and filled three freight cars. It was laid on Sunday, April 16, between the two tracks of the Boston and Providence Railroad, the south end being at Attleboro, Mass., and the north end at West Mansfield. The entire length of the cable was about a hundred feet over five miles. It was divided into sections of 530 feet in length, each section coiled on a separate reel. A trench varying from eight to twelve inches in depth was made, in which the cable was buried, the two ends of each adjoining section being connected by screw connections in test boxes, placed at the required positions. Several lengths of the cable being uncompleted, the work of laying could not be finished until the following Sunday, April 23. The upper room at Attleboro Station is to be the testing room, and it is expected that valuable knowledge will be gained by the proposed experiments, which will be conducted by the electricians of the American Bell Telephone Company."

THE CITY AND ELECTRIC LIGHTING.—At a meeting of the City Commissioners of Sewers, on Tuesday last, when the subject of lighting the city was under consideration, Mr. Innes moved "That leave and license be given to electric lighting companies, who are lighting public ways, to light private property on the lines of their conductors." The cost of lighting by electricity would be very much reduced if the companies were allowed to supply houses along the line of their conductors. The committee had been seriously considering the vast expense which would be necessary in carrying out any system of electric light, and already one system had had to be abandoned on account of the very heavy expenditure. He thought he was betraying no secrets of the committee when he said that the contracts they had had before them showed that the electric lighting would involve an expenditure of over five or six times as much as the amount which was now incurred in lighting by gas. However, in most cases it was shown that the charge for the electric light itself was not so much, but that it was the charges incidental to initiating the system which were so very heavy. He considered that if any contracts were entered into at the end of the year a very considerable increase would have to be made in the rates of the City; and the committee viewed the amount of the expenditure in this particular with very considerable alarm.—Mr. Peebles seconded the motion, and spoke against the form in which the tenders for the electric light had been invited. He thought that it was only fair to the companies that a standard should have been laid down for the electricians to work to.—Mr. E. E. Ashby argued that the adoption of such a motion as the one proposed might lead to very great diffi-

Digitized by Google

culties with the gas companies, on whom they had to fall back in case of accident. They must try before they entered into anything of that kind to arrange matters with the gas companies in an honourable and friendly manner. He thought the whole committee was in favour of electricity, but then it might turn out that, although it was a success as a light, it was too costly for general use. The committee did not desire to run up the rates in any way.—After some further discussion, Mr. Innes withdrew his motion.

Cost of Electric Lighting.—Mr. C. M'L. Hardy contributes a letter to *The Times* of 2nd June on the above subject, from which we extract the following:—"Electricity costs about one farthing per lamp of from 16 to 20 candle-power, as will be seen from the following. One horse-power will generate electricity to keep incandescent eight to 10 lamps, giving from 16 to 20 candle-power each. One horse-power consumes from 2½lb. to 3lb. of coal per hour. Two thousand lamps would, therefore, require from 4½cwt. to 7cwt. of coal per hour, which, at 15s. per ton, will amount to 3s. 4½d. or 5s. 3d. per hour, according as we take the more favourable or unfavourable expenditure. The cost for the installation and for the annual maintenance for 2,000 lamps of from 16 to 20 candle-power each will be approximately as follows:—

—	Installation.	Depreciation or cost of maintaining.	
Building	£200	at 3 per cent.	£6
200 H.-P. Engine	1,000	at 5 per cent.	50
Boilers & Furnace	500	at 7 per cent.	35
Dynamo Machines	1,000 to 2,000	at 2 per cent.	20 to 40
Leads and Fittings for 2,000 lamps, exclusive of lamps	1,500	at 2 per cent.	30
	£4,200 to £5,200		£141 to £181

Say £5,500 at £200 per annum.

Lamps lighted at dusk and extinguished at midnight will be burning 2,000 hours per annum and the annual cost will be as follows:—Interest at 5 per cent. £275, replacement, &c., £1,200, replacement of lamps £1,000, coal £500, engine-driver £100, stoker £50, electrician £150, rent of premises £100, sundries £125, total £2,500 per annum—that is to say, including 5 per cent. interest on the capital invested the cost per annum of 2,000 lamps giving from 16 to 20 candle-power will be £2,500, or 25s. per lamp per annum for 2,000 hours. Twenty-five shillings, or 300 pence, for 2,000 lamps for one hour is 30 pence for 200 lamps for one hour, or about 1d. per lamp for seven hours. Gas costs one farthing per lamp of six to eight candle-power per hour, as will be seen from the following:—1,000ft. gas, at 4s. 2d. equals 50d. per 1,000, or 1d. for 20ft.; 1,000ft. gas at 3s. 4d. equals 40d. per 1,000, or 1d. for 25ft. An ordinary burner consumes from 5ft. to 8ft. per hour, or at a cost of one farthing for a lamp of from six to eight candle-power. In considering the foregoing *data* the two following important facts should be borne in mind in favour of electricity:—First, in the cost for electricity the whole of the lamps, fittings, &c., are included, whereas with gas the consumers are supplied with the gas, but have to provide themselves with fittings, such as gas brackets, globes, &c.; second, the foregoing calculations are based on the assumption that the plant for generating the electricity cannot be utilised for quite six out of every twenty-four hours, whereas, by the adoption of secondary batteries (better known as accumulators, or storage batteries), by a comparatively trifling additional outlay, the same engines, boilers, dynamos, &c., may be utilised for about three to four times as many lamps, and so considerably reduce the cost."

Progress of Telegraphic Business.—The following extract from Mr. Preece's article on "The Age of Electricity," in *Time* for June, is interesting:—"The growth of telegraphic business in this country has been enormous, as is shown by the following figures: 1851—miles of wire, 7,303; number of stations, 198; number of messages, 48,490. 1862—miles of wire, 57,879; number of stations, 1,616; number of messages, 2,676,354. 1872—miles of wire, 87,719; number of stations, 5,179; number of messages, 15,500,000. 1881—miles of wire, 121,052; number of stations, 5,637; number of messages, 31,345,861. In 1852 it was mentioned, as an extraordinary fact, that 1,000 messages passed through the head telegraph office, in London, in one day. In 1872 the greatest number per day was 28,508, but in 1881 the number reached in one day was 60,471. The instruments fixed which, in the year 1869, when the Government took the telegraphs in hand, were 2,200, now exceed 13,000. The news which then reached only 144 towns is now supplied to 326 towns. The 173 newspapers that received this news have now increased to 525. While only six special wires were handed to these newspapers after business hours, there are now no less than 29 wires which are used solely by newspapers for their own purposes and their own advantages. The growth of business in the central telegraph station has been wonderful. No less than 14,300,000 messages passed through this office during the past year, of which 1,650,000 were local messages to the metropolis alone. There are in use at this office the following instruments:—140 single needles, 200 Morse inkers, 170 Morse sounders, 65 Wheatstone automatics, and 12 quadruplex. When the Electric Telegraph Company was first incorporated, in the year 1846, the rates to the public for the transmission of messages were a penny per word per mile for the first fifty miles, a halfpenny per word per mile for the next fifty miles, and a farthing per word per mile beyond one hundred miles. In March, 1850, this exorbitant tariff was so far reduced as to make 10s. the maximum charge, and in March, 1851, this was still further reduced to 8s. 6d. On the 17th November, 1851, the charge was again reduced to 2s. 6d. for 20 words within 100 miles, and 5s. for 20 words beyond that distance. Subsequently the charge was reduced to 1s. for 20 words within 100 miles, 1s. 6d. within 200 miles, 2s. within 300 miles, 3s. over 300 miles, and 4s. to Ireland. There was also a local rate of 6d. in some towns, but this was illusory, for the charge for porterage brought it to 1s. and over. Since, however, the telegraphs have been transferred to the State, an uniform charge of 1s. for twenty words has been made for the whole of the United Kingdom. Thus, a charge which was originally 4s. 2d. per word is now less than ¾d. per word, and there is a prospect of this rate being still further reduced to ½d. per word, with a minimum charge of 6d. In all these cases the addresses have been sent free, and this privilege has not only been very seriously abused, but it adds considerably to the cost of the transmission of messages, and offers an obstacle to the cheapening of telegraphy. As a peculiar instance of the result of a free address, the following was sent from Sherborne, and was delivered to 'Jim Pearce, a little boy in charge of a horse and gig, in a field called "Eight Acres," just above the railway station, Shepton Mallet, belonging to Mr. Giles, Farringdon Gurney.' If the public desire further cheapening in the transmission of their messages, they will, probably, have to forego the privilege of having their addresses sent free."

THE PHENOMENA OF THE ELECTRIC DISCHARGE WITH 14,400 CHLORIDE OF SILVER CELLS.*

BY WARREN DE LA RUE, ESQ., F.R.S., SEC. R.I., ETC.

For the last six years I have, in conjunction with my friend Dr. Hugo Müller, been engaged with experiments on the electric discharge, using as the source of electricity a constant voltaic battery which we devised. It is in principle the same as that invented by Daniell, but in our battery a solid electrolyte, insoluble in water, or a weak saline solution—namely, chloride of silver, replaces the soluble sulphate of copper, so that no porous cell is needed in the chloride of silver battery. The results of our experiments my colleagues think of sufficient interest to be brought under the notice of the members of the Royal Institution, and I will endeavour to make them as clear as possible in the limited time at our disposal. I must, however, ask your kind indulgence if I fail, as I have not the practice of lecturing. It is true that it is not the first time that I have had the honour to occupy this chair, which I did upwards of forty years ago.

I may as well commence by describing the tool which I am about to use in the experiments. The diagrams will help you to understand it. The chloride of silver battery is made up as follows:—A glass tube $\frac{1}{8}$in. in diameter, $5\frac{1}{2}$in. long, and containing about 2 fluid ounces of liquid. Into this is fitted a paraffin stopper with two holes perforated through it; through one of these a zinc rod, 3-16in. diameter and $5\frac{1}{2}$in. long, is inserted, and fastened by melting a little of the paraffin around it; the other element is formed of a flattened silver wire, which passes between the stopper and the glass, so that the metallic elements are zinc and silver. On the flattened silver wire is cast the electrolyte—namely, a rod of chloride of silver $2\frac{1}{2}$in. long and 5-16in. diameter—and the cell is charged through the second perforation in the stopper with a solution of chloride of ammonium containing $2\frac{1}{2}$ per cent. of salt (Fig. 1). When the circuit is not closed—that is, when the silver element is not connected by means of a conductor to the zinc—no action whatever takes place; and in proof of this I may state that I have a battery which was made up more than six years ago, and is still in action, loss

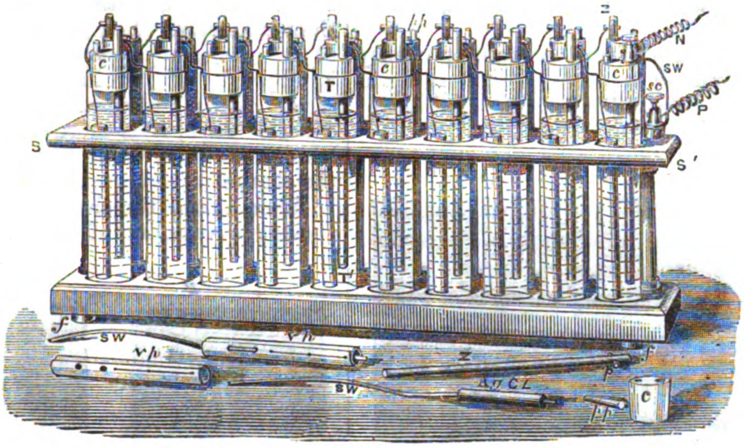

FIG. 1.

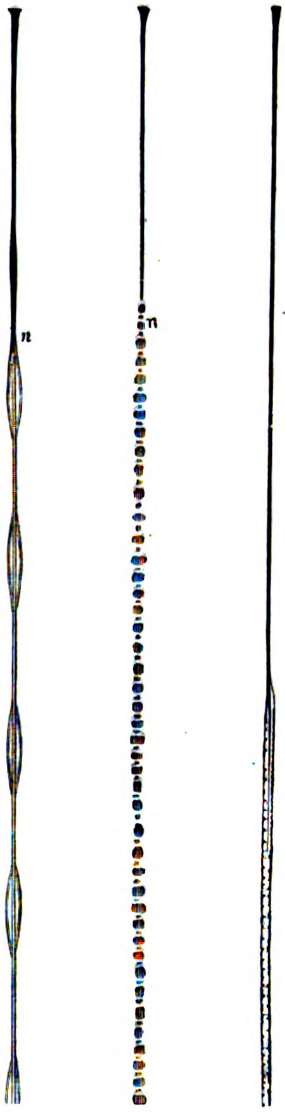

FIG. 3.

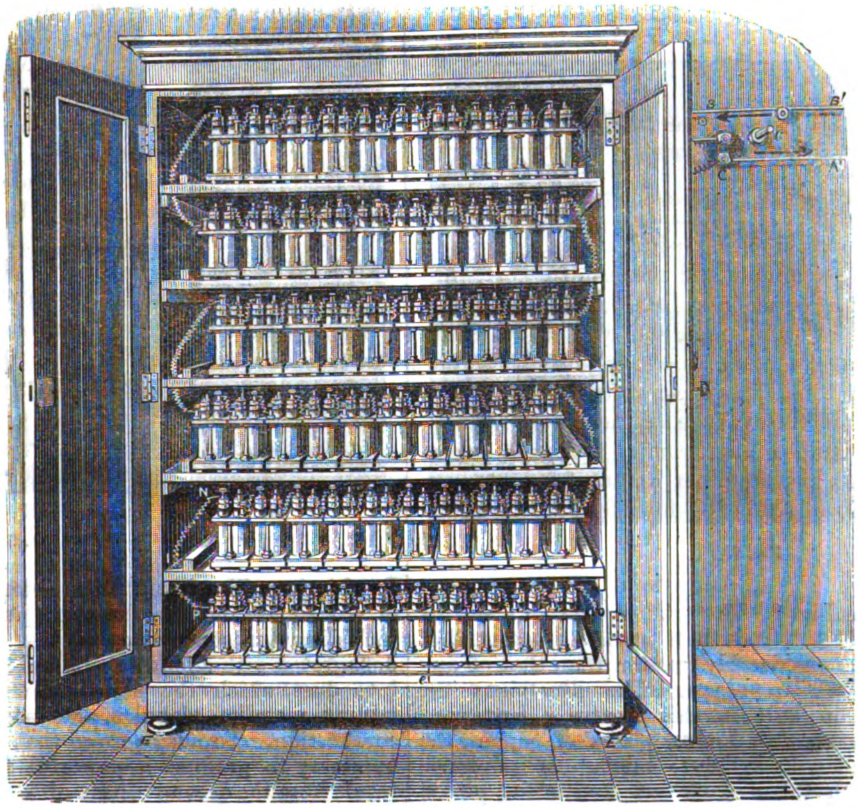

FIG. 2.

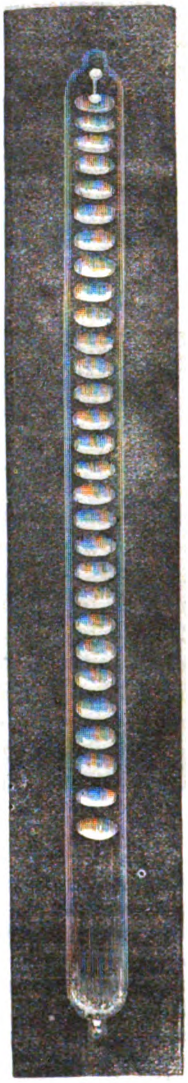

FIG. 4.

* Reprinted, by permission, from the *Proceedings* of the Royal Institution.

Digitized by Google

of the fluid by evaporation having been from time to time made up. But as soon as connection is established, then the chloride of silver parts with its chlorine and the zinc dissolves, and metallic silver is separated, in a spongy state, from the chloride, and remains attached to the silver wire, retaining still the form of a rod. Such an element has the electromotive force of a volt (nearly 1·03 volt).

A volt is that electromotive force which, working through a resistance of one ohm, would deposit 0·0011363 gramme of silver from a salt of silver; or decompose 0·0000947 gramme (0·00146 grain) of water in one second.

A column of mercury at 0° Cent., one square millimetre in section, and 1·05 metre high, offers a resistance of 1 ohm; a pure copper wire, 1-16in. diameter and 129 yards long, offers a resistance of an ohm.

These cells are grouped together in trays containing twenty or more, and the trays are placed in cabinets containing in some instances 1,200 cells, in others 2,160 cells; a cabinet of 1,200 cells is shown in Fig. 2. The total number of elements I am about to use is 14,400, and these possess a potential of 14,832 volts, which is considerably greater than that of any battery hitherto united in series. The illustrious Sir Humphry Davy used in 1808, in this theatre, a battery of 2,000 plates, 4in. square, with double plates of copper, the battery being charged with a dilute mixture of sulphuric and nitric acids. With this magnificent instrument, placed at his disposal by the subscriptions of a few patrons of science, he obtained a spark 1-40th to 1-30th of an inch, when the terminals were made to approach each other (a striking distance of 1-40th of an inch would accord with our experiments with the chloride of silver battery, if the difference of potential of the two batteries is taken into account). When the discharge had once taken place then the terminals might be separated four inches without causing its discontinuance.

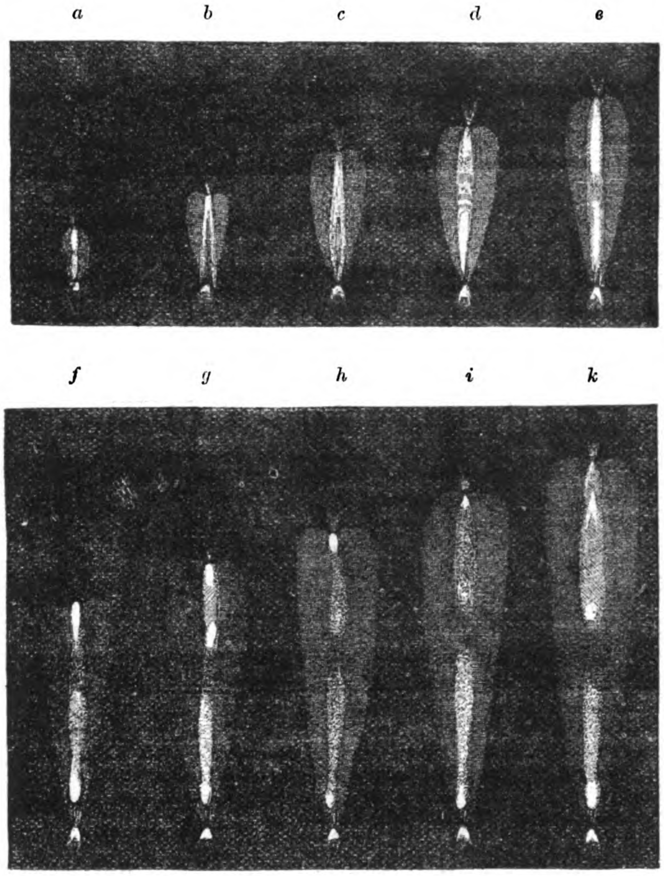

Fig. 5.

My friend, the late Mr. Gassiot, constructed several batteries of high potential, and at the time of his death there were 3,000 Leclanché cells in action at his laboratory. On January 26, 1875, I measured the length of the spark between points, and found it to be 0·025 inch; 3,000 of our cells produced a spark of more than twice this length, namely, 0·0564 inch, on account of its better insulation. I propose, in order to show the power we have at command, in the first instance to accumulate, by means of a condenser, the electricity from 3,240 cells, and to send its charge through a platinum wire 1-80th of an inch thick. In charging the condenser I will pass the current through a voltameter, in order that you may judge of the very small chemical force concerned in the production of the enormous mechanical effect of the electric discharge. I may as well at once tell you that the current necessary to charge the condenser I am employing would decompose merely 1-5,000th of a grain of water. I will first of all pass the current from twenty cells through the voltameter. You will see that there is a rapid evolution of mixed gases (oxygen and hydrogen) into which the water is resolved. The evolution of gas, you will at once perceive, is very much slower when the current is charging the condenser. Also, it is more rapid at first and then gradually lessens, and would entirely cease if there were no leakage of the charge.

When I send the charge of the condenser, which has the enormous capacity of 42·8 microfarads (or equal to 6,485

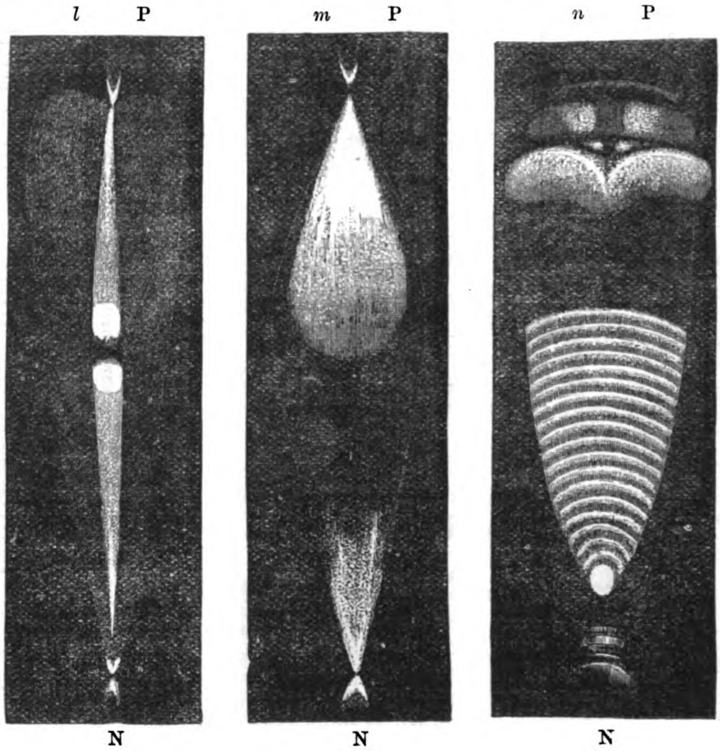

Fig. 5a.

Leyden jars, like that I have before me, which has coatings of 442 square inches), through $2\frac{1}{2}$in. of gold wire, 1-80th of inch diameter, strained on a glass plate, it will be violently deflagrated with a loud report, and the metal will be scattered into dust, which the microscope shows to be composed of minute metallic globules, and not an oxide resulting from combustion. Faraday proved that the quantity of electricity necessary to produce a powerful flash of lightning would result from the decomposition of a single grain of water. This can be realised when it is remembered that it would be 5,000 times as great as the charge of the 42·8 microfarads condenser just shown you. If we place the glass plate on which the wire was strained before the microscope, then it will be perceived that the distribution of particles of gold is not uniform along the space which the wire occupied, but on the contrary, they present a stratified appearance, indicating a series of pulsations during the apparently instantaneous discharge. I hope to show you shortly that the most steady discharge through a vacuum tube is in reality intermittent.

As I shall for this purpose cause the current passing through the tube to pass at the same time through an induc-

Digitized by Google

tion coil so as to induce a secondary current, I will render evident to you in a striking manner that where electricity is caused to pass through a wire it induces another or secondary current in an adjacent wire. I have here two insulated wires, each 350 yards long, coiled side by side on a reel; to the extremities of one coil is attached a platinum wire six inches long and 1-500in. diameter; through the other coil I will send the charge of electricity from a condenser of seven microfarads capacity (about the sixth of that just used) charged with 10,800 cells. You perceive that the platinum wire is violently deflagrated with a loud report by the induced current.

The mechanical effects produced by the charge of a condenser are as the square of the number of cells used to charge it, and although the condenser which I have just used has only one-sixth of the capacity of that I first showed you, yet its mechanical effects are nearly twice as great; for the square of 10,800 is to the square of 3,240 as 11 to 1. In order to show the enormous power of its charge I will send it through 29 inches of platinum wire 1-100th of an inch in diameter; this is immediately deflagrated. And if I allow the charge to pass between the terminals of a discharger the loud report of the spark renders evident the enormous power stored up by the condenser. I had hoped to show you the condenser charged with 14,400 cells, but it is not capable of withstanding this potential, for one after the other of the coated glass plates of which it is made up has broken down with the charge shortly before the lecture.

In order to afford you an opportunity of forming a pictorial conception of that which it is wished to convey, respecting the stratified discharge, I will recall to your recollection an experiment often shown to you by Dr. Tyndall (Fig. 3). With a reservoir of water, placed at a height of a few feet, when the tap at the lower portion is turned on the water flows out, apparently in a continuous stream; but when the thread of water is examined by means of an intermittent beam of light, it is at once seen that the flow is not continuous, but (in consequence of the tendency of water to assume a globular form) the stream as it descends breaks up into a series of drops, one following the other in rapid succession. It is not my purpose here to refer to the cause of the phenomenon, which has been explained to you by Dr. Tyndall in his lectures on Sound, but only to recall this elegant experiment in order to present a mental picture of what may occur in the aggregation of the molecules of gases conveying electricity.

Now, I will cause a discharge of electricity to pass through a vacuum tube containing residual carbonic acid at a pressure of 0·5 millim. (Fig. 4), and you will at once perceive that the residual gas groups itself into a series of luminous strata, the molecules which composed them being held together by the balance of electric forces, where, as in the case of the water streams, the particles composing the globules are held together by cohesive attraction. The strata do not flow on like the drops of water, but remain stationary; they are, as it were, so many Leyden jars charged on one side with positive and the other with negative electricity; each imparts say its positive charge to the next negative end of the succeeding stratum, and receives a charge from that behind it; and thus the flow of electricity goes on from one terminal to the other without any movement of the strata necessarily taking place. If we examine the electric arc passing between the terminals of a battery, either at ordinary atmospheric pressure or at other less pressures, it is seen that there is a resemblance to the discharge in vacuum tubes, the light emitted by different parts of it not having the same intensity throughout, and that under most circumstances there is a tendency to break up into distinct entities of the nature of strata, and ultimately to take a stratified appearance like the discharge in vacuum tubes. From this we may infer that the discharge in a vacuum tube is, in reality, a magnified arc. I cannot show these phenomena in a way that you could make them out at the distance you are from me, but I will, with the assistance of Mr. Cottrell, exhibit to you copies of photographs of the arc in atmospheric air (a to n, Figs. 5 and 5A), taken in my laboratory under various conditions as to distance beween the terminals and pressure, as set forth in the table given in next column.

I can let you see the arc, although I am unable to show the details of its structure; thus, when I move the discharging key, the arc passes between the two points, 0·7 inch apart, fixed in the micrometer discharger (Fig. 6), in which, however, the terminals shown consist of a point and disc, instead of two points, which I am now using. And I may mention that before the discharge takes place there is neither con-

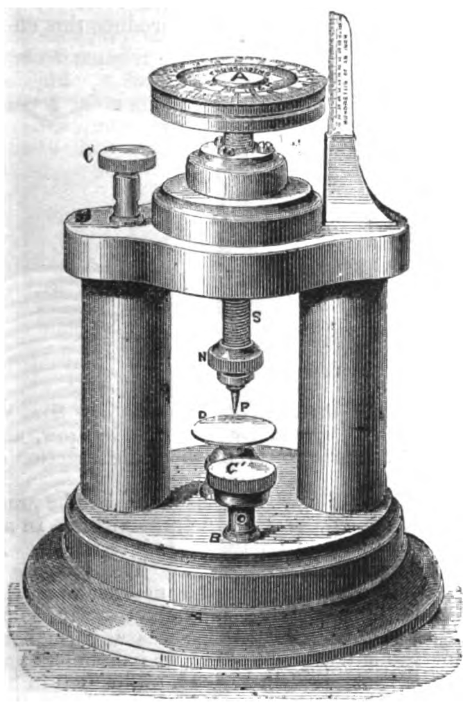

FIG. 6.

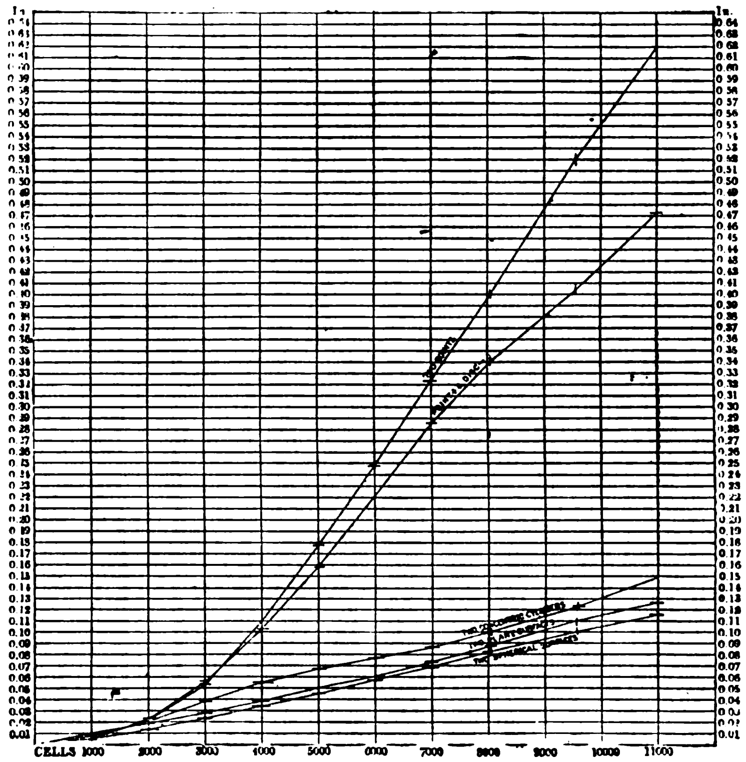

FIG. 7

densation nor dilatation of a gaseous medium in contiguity with the charged terminals, as has been suggested, whatever may be the form. The length of the arc varies with the potential of the battery and with the forms of the terminals; between points, the length of the striking distance increases as the square of the number of cells employed. Thus, with 11,000 cells it is 0·62in., as shown in the diagram (Fig. 7). The potential of 11,000 cells put our means of insulation to a severe test, and 14,400 cells overcomes it to such an extent as to interfere so seriously with the striking distance that I only obtain a spark 0·7 inch long.

Fig.	Distance.	Pressure.		Cells.	Current

On the supposition that a cloud would act very much as a mere point at the great distance at which a lightning discharge occurs between clouds or a cloud and the earth, we may from these data calculate the potential necessary to produce a lightning flash a mile, or 63,360 inches long. It would require nearly 243 units of 14,400 cells united in series, or say 3,500,000 cells about.

The striking distance may be increased by an arrangement of condensers to form what is called a cascade, and in this way I shall be able to produce a spark an inch long with only 1,200 cells. Such a battery I now use to charge twenty-five plates of a small condenser, and by means of a rotating commutator, connect, so to speak, the outside of one plate to the inside of the next, and thus multiply the potential twenty-five times; 4,200 cells have, as you see, a very short striking distance; it is only 0·00608in., so that the spark obtained with the cascade is 164 times as long as with the battery alone. If there were no loss in converting quantity into potential, it would be 625 times or the square of 25. The apparatus I am using is the so-called Rheostat of Gaston-Planté. Franklin, it will be remembered, was the inventor of the cascade. It is not impossible that the effects of lighting may at times be increased by a kind of cascade arrangement formed by the charged layers of cloud floating one over the other.

(TO BE CONTINUED.)

THE TELEPHONE CASE.

(CONTINUED FROM PAGE 57.)

Sir W. THOMSON testified that the medium used in an Edison telephone for the purpose of varying the current must be semi-conducting, or such that, by varying the pressure between it and another substance, the resistance should vary, and hence the current inversely, also that it should be capable of itself, or by force of some arrangement, of recovering its normal position. It was not known in 1876, but is now known, through experiments of Sir W. Thomson, that carbon in one form may be equivalent to carbon in another form, both as regards initial conductivity and power of varying under pressure. The automatic action of the semi-conducting substance in great measure depends upon the position in which the carbonaceous particles are put in the circuit. In his cross-examination by Mr. Hemming the following questions and answers were given :—

"Mr. HEMMING: What was it Bell invented or discovered with reference to the iron disc which you say was such an important discovery as to deserve a patent?—A. That disc, that simple round iron disc, clamped with wood, now mechanically clamped round the edge in the neighbourhood of a magnetic pole, was capable of producing all the motions of the air required for articulate speech. I may say it is a most surprising discovery that after what I had seen with that Glasgow instrument, after what I had heard at Philadelphia, I was exceedingly surprised when, many months afterwards, I was first presented with the modern Bell receiver. At Philadelphia and in Glasgow I would not have thought it possible that that instrument could produce this result; and I am perfectly sure I speak the unanimous feeling of everyone who knows anything of electricity in the world when I say that if that ordinary Bell receiver was put into the hands of any living person, and he was asked 'could that produce the effect?' he would have said, 'I do not believe it possible—it is a mere chimera.'

. . . .

"Mr. HEMMING: I understand you rightly, I think. You say, even after this publication of the 11th of August, 1876, which described the old instrument of Bell, it was unknown that it was possible to get the same action out of iron?—A. It was supposed that a powerful electro-magnet was necessary, and the only way shown of obtaining that powerful electro-magnet was by a current in the line wire, which might have to be a very powerful magnet. Some Bunsen cells—I never knew how many—were used by Bell at Philadelphia, and I myself all the time was under the impression that it was a kind of effect that would require very powerful appliances, and to find afterwards the very simple appliance in that well-known Bell receiver, that little bit of steel with the magnetism, would produce this effect is a tremendous discovery."

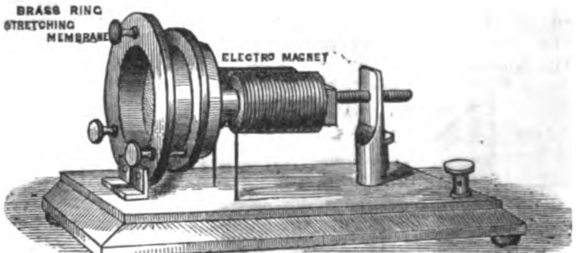

FIG. 9.—Glasgow Transmitter.

Figs. 9 and 10 show the instruments brought by Sir W. Thomson from America, and shown by him at Glasgow, and mentioned by him in his address to the mathematical section of the British Association.

The Hunnings transmitter Sir W. Thomson held to be practically the some instrument as the Edison transmitter. In all practical and theoretical respects it is the same instrument. It is obviously intended for the same purpose. The purpose is obviously attained by operating in a similar manner upon the same properties of material. There is substantially some difference of detail. As to the receiver there was a permanent magnet in the Bell instrument. The Cox-Walker instrument had an electro-magnet. It is illustrated in Fig. 11. But Bell in his specification describes electro-magnets as being interchangeable with steel magnets. The Cox-Walker instrument was not adapted to work merely by local circuit; there must be a current through the line wire. Bell's instrument could work with an alternating current.

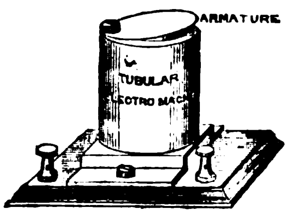

FIG. 10.—Glasgow Receiver.

In Fig. 12 we illustrate Hunnings's instrument, which the plaintiffs assert is an infringement. This instrument was patented by Mr. Hunnings, who is a clergyman, on the 16th of September, 1878, about fourteen months after the date of Edison's patent. Mr. Hunnings states that his apparatus consists of one or two vibrating diaphragms, composed wholly or in part of suitable metal, such as, preferably, platinum, silver, ferrotype iron, tinned iron, &c., placed in close proximity to each other, and connected respectively with the opposite poles of a galvanic battery. The receiving telephone being in circuit, the

Digitized by Google

intervening space is filled with carbon or other suitable conducting substance—preferably in the form of powder—and about $\frac{1}{16}$in. in depth. The whole is secured in a box of suitable non-conducting material with a mouthpiece. The great feature claimed by Mr. Hunnings is the use of carbon in a state of fine loose powder, not in any way compressed or consolidated. Mr. Hunnings does not claim the principle of using carbon in the solid or consolidated form to increase or diminish the resistance of a telephonic current for the purpose of transmitting sounds, as this is well exemplified in the well-known Hughes microphone and the Edison carbon telephone; but he does claim the use of finely powdered carbon in the loose or free state as a means of varying the resistance of a telephonic circuit by the vibrations of a thin metallic diaphragm enclosing it, controlled by the sound waves impinging on it. Thus it will be seen that the point made by the defendants is that they used powdered carbon, by preference engine coke crushed but not ground fine, whereas Edison uses carbon in a consolidated form. We have already given the claims of the Bell patent, and those made by Edison. It will be well, however, to again point out that they are said to cover the use of a diaphragm in a telephone, the eleventh claim running:—"The combination with an electro-magnet of a plate of iron or steel, or other material capable of inductive action, which can be thrown into vibration by the movement of surrounding air, or by the attraction of a magnet." It is, of course, alleged by the plaintiffs that such a plate is found in the Cox-Walker receiver.

Dr. JOHN HOPKINSON deposed that in Bell's patent there are two several novelties. One of those is the substitution of a plate diaphragm, carried in a way described in the drawings of the specification, in lieu of a diaphragm of metal, such as of a membranous character. The second invention is the use of a permanent magnet in a telephone, instead of an electro magnet excited by a battery in the single circuit of the line wire, or instead of that permanent magnet its obvious equivalent, an electro magnet excited by a battery which has nothing to do with the line wire.

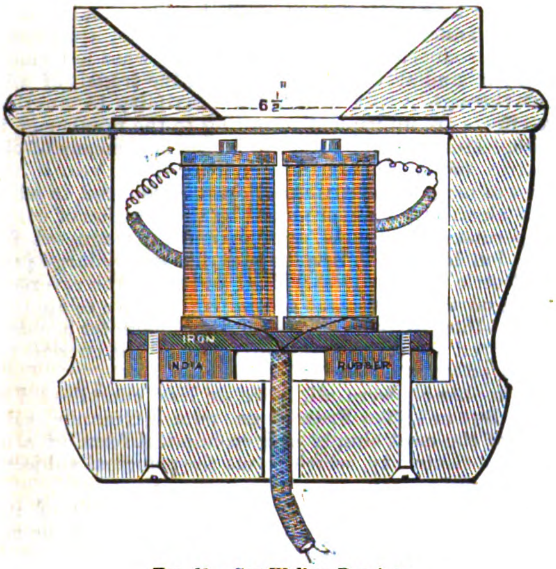

FIG. 11.—Cox-Walker Receiver.

It was stated by this witness that the resistance of the coil of the instrument shown by Sir W. Thomson to the British Association at Glasgow is 1,450 ohms.

Mr. JOHN IMRAY stated that he had successfully made a pair of instruments from Morgan Brown's (Bell's) specification.

Mr. EDWARD STEBBINS JOHNSON said that Edison in 1876 began to work at the telephone as now known, but that he has for some years been experimenting in acoustic telegraphy. Mr. Johnson stated that the Edison instrument with plumbago on silk worked well, in fact with plumbago in any shape put into it, and that he had tried every form of tension-regulator described in the specification.

The examination of the plaintiffs' witnesses ended and that of the defendants' commenced with

Mr. HERBERT JOHN ALLISON, who testified as to the publicity of specifications and pamphlets at the Patent Office library.

Rev. HENRY HUNNINGS stated that he commenced experiments with the telephone immediately after the British Association meeting at Plymouth, 1877, and in November of that year he made a transmitter, consisting of a mouth-piece, an iron plate, a piece of platinum slightly dented, then a screw carefully turned in the lathe to fit into this dent, and so adjusted it backwards and forwards to try and make it speak. He tried an instrument on a special line between the Archbishop of York's Palace and the vicarage either at the end of November or the beginning of December, 1877, but it did not answer well. About April, 1878, a peculiar transmitter was tried, which consisted of a lidless box about two feet long, with a piece of paper glued on. An electrode was applied at one end, also at the other with a line of cinders from the grate. On speaking to the line of cinders the reply came back, "Yes, I hear." Then a piece of engine coke was found, and ground up into particles, which were placed between two pieces of paper. The witness said, "I turned a wooden ring in my lathe between two inches in diameter and ⅜in. thick. Of course, I must have something on each side of this ring to hold the grains of coke, or otherwise they would tumble through, so I placed paper with a piece of tin foil in it, and another paper the other end with tinfoil, and stick those things in three screws." . . . I found that to answer very well, so I went on until the instrument took the form it is now in." The witness, asked to state what he considered the distinction of principle in Edison's transmitter from his own, said: "All through Edison's specification I find that he works upon the pressure system. My principle is the loose points of contact, and the reason that I made use of this oven-made engine coke . . . . was because, taken bulk by bulk, its specific gravity is the lightest thing I can find, so that sound waves can move about these particles very easily." The witness also stated that "if you pack up grains of coke together tightly the instrument will not answer, it (the coke) must be in a perfectly loose condition, so that you can hear the grains shake about."

Mr. THOMAS AUGUSTUS WATSON, the maker of Bell's instruments shown at Philadelphia in 1876, and of those brought to England by Sir W. Thomson, stated that when he saw the finished instrument "the diaphragm laid flat on the top of the box."

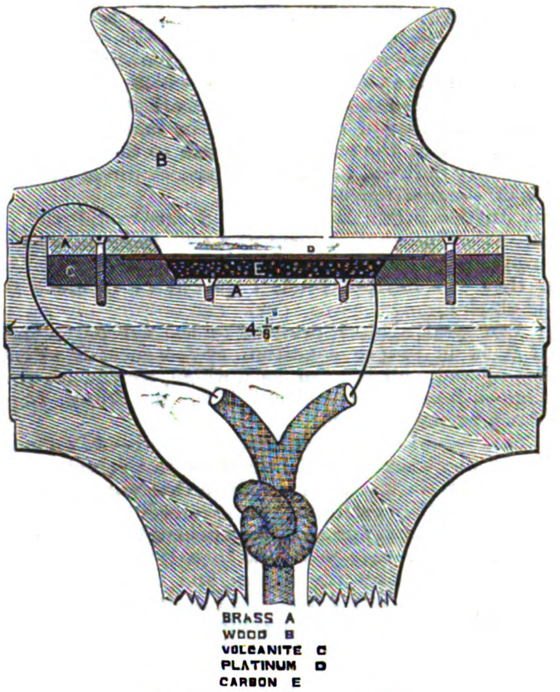

FIG. 12.—Hunnings' Transmitter.

Professor SILVANUS PHILLIPS THOMPSON showed that the Glasgow receiver would act by arranging it to act in the hands of Mr. Justice Fry, and suggested the failure at Glasgow to have been caused by a bad transmitter or bad connections. Asked to explain the difference between a tuning fork and a tympan, he said: "A tuning fork has two prongs, which, when it vibrates, approach to one another like a couple of doors opening or shutting on their hinges, with this difference, that there is no hinge, and, therefore, the metal must bend. That is what a tuning fork is intended for, and it is made perfectly stiff and thick that it should only vibrate in that manner, the two prongs waving to and fro as a whole. If it were thin it would vibrate in a nodal manner with nodes superposed on it, as a reed does in the case of a harmonium. They vibrate like tuning forks, except they break up into ripples; they are not tympans, but reeds. But a tympan, when it vibrates, vibrates in its fundamental node as a whole, or also with ripples; but there is this distinction, the fundamental node being that the tympan bulges in and out alternately on the upper and lower surface. But, besides that fundamental node, there are higher nodes corresponding with

Digitized by Google

the high nodes of vibration of a tuning fork or a reed. If you impose on a tympan a higher node of vibration, no matter whether it has a central attachment or is perfectly free all over the surface, these high nodes will consist in there being ripples, concentric ripples, round the centre. The whole surface is thrown into concentric circles, like those you see in a pond when anything is thrown in, and every portion of the tympan in concentric circles is rippling up and down with circles, nodal lines all round; so there is this perfectly well marked distinction between tympanic vibration and the vibration of the tuning fork. In one case you have ripples in circles, in the other case in straight lines."

Professor Silvanus Thompson's evidence concerning the Hunnings and Edison transmitters may be given in full. Thus:—

Q. And you have worked with an Edison transmitter and with a Hunnings transmitter?—A. I have.

Q. Having those two instruments in your hand, will you say whether there are any differences in principle between the mode in which they work, and if there are any, what you consider those differences?—A. The differences are very striking. In the first place, there is in the Edison transmitter this mechanical arrangement, this mechanism for collecting the sound waves from the air, and transmitting them mechanically through this arrangement to the mass below, which is under artificial compression by means of a screw below it.

Mr. Justice FRY: That is, you mean there is a diaphragm, a tympan, and a cork?—A. Yes. In the other we have no tympan or cork to press artificially downwards, no screw to make that pressure upwards. We have, or rather we should have, if this were in good condition, a lot of loose grains of coke under the platinum electrode, and resting on a solid table of brass.

Mr. PEARSON: Those are the differences in the construction. Now, in the principle of working, what is the difference in the principle of working in the two instruments?—A. It is this, that the vibrations of the air are collected by this mechanism, and impressed upon the mass underneath, the mass already under elastic compression, and its resistance is thereby caused to vary. In this other case we have a thin, comparatively loose piece of platinum foil—the electrode, in fact, which, when you talk to it, shakes, and shakes the carbon underneath it, producing a larger or smaller number of contacts, and in that way the resistance to the passage of the current is varied, so the action in one case is physically indirect, in the other case as direct as the arrangements of the instruments admitted.

Mr. Justice FRY: In the second case would the electrodes vibrate as a tympan?—A. Not as a true tympan, because it cannot ripple in circuits as the true tympan can.

Q. How will it ripple?—A. I question very much whether it would ripple.

Q. You speak about it pressing on the carbon underneath?—A. If it is in proper condition of looseness it will simply be pushed up and pulled down, as a whole, by the air-waves that impinge on it as the little electrode in the Edison is pushed up and down by the pressure.

Q. That would be the resultant of waves?—A. Of waves themselves, in any case. All the air does in a sound wave, a plane wave, is that the particles of air in that wave move backwards and forwards, they oscillate, and then oscillate this piece of foil and make more or fewer contacts against the loose coke underneath. In either case you talk to a tympan; that is to say, a drumhead which is set into ripples, and those ripples have nodal lines in circles all round, and the resultant of those, with more or less imperfection, as represented by the movement up and down at the central point. I draw a complete distinction between the motion you have in the tympan itself and in the platinum electrode at the bottom.

Q. Supposing the same sound is uttered to an Edison transmitter and to a Hunnings transmitter, will the up and down motion result in the cork of the one and in the platinum foil of the other?—A. Very nearly, but in the case of the Hunnings that would be more true to the real vibrations of the sound than in the case of the Edison.

Q. There would be a certain amount of disturbance in the transmission?—A. Yes, the mechanism necessarily implies that you loose something.

Q. But, subject to that loss, the up and down motion to which you speak, the same utterance of sound is the same with the cork in one and the platinum in the other?—A. The two electrodes move up and down absolutely identically, subject to the necessary imperfections on account of the mechanism of the cork.

Q. I suppose those principles which lead to those similar results were familar to persons familiar with acoustics?—A. I am not quite clear how much we knew at that date. It was known that a tympan when it vibrated rippled in circles; it was known that the central point would represent more or less accurately the resultant of the motions imparted to the tympan; and it was also known, what Sir William Thomson explained when he was in this place, that a limp, a perfectly limp sheet, acted upon by the waves of the air, would follow every wave of the air without being thrown into ripples upon its surface. But I think I am justified in saying that in the case of the Hunnings transmitter we realise the direct action as nearly as we can, whereas in the Edison transmitter we have this mechanism, which first takes these waves which move up and down, and causes them to set this tympan rippling, and then takes the resultant or, as far as can be, the resultant of those ripples as a central point, and pumps that into the electrode.

Q. In the Hunnings you get the up and down motion from the voice direct on to the particles?—A. Yes.

Q. In the other case you translate it into nodal waves, retranslate the nodal waves into an up and down motion?—A. Your lordship has expressed it precisely.

Mr. PEARSON: May I take it that you do not consider platinum foil, the electrode in Hunnings's instrument, the same thing as the tympan in Edison's instrument?—A. No, because it acts in entirely a different way, it corresponds to the platinum electrode in Edison's.

Q. Inside the case in Edison's, the one I put into your hand, you have plumbago fine?—A. Yes.

(TO BE CONTINUED.)

ON THE GRAMME DYNAMO MACHINE AND THE ELECTRIC LAMPS EXHIBITED BY THE BRITISH ELECTRIC LIGHT COMPANY.*

BY EDWARD B. BRIGHT, C.E.

About half a century ago the connection between electricity and magnetism was discovered, and that if a current of electricity was passed through a wire parallel and adjacent to a magnet suspended on an axis, the magnet would be deflected to the right or left according to its polarity and the direction of the current.

In like manner if a magnet is moved across a wire an electric current is produced in the wire. This is what is termed induction, and a similar effect results from the transit of an electric current through a wire placed in proximity to another wire. These effects are multiplied according to the number of turns of the wire. Motion being found to be the best means of obtaining an electric current, there had been, prior to the year 1870, several varieties of magneto-electric machines introduced in which currents of electricity were produced by the rotation of coils of wire before permanent magnets, or of permanent magnets before coils of wire; but in these it may be said that a very large proportion of the electric power was sacrificed owing to the reverse current occurring on the movement of one coil of wire to another being lost. In other early machines of this character a commutator was employed to reverse the direction of the current for each change of polarity.

These appliances were all, more or less, complicated and defective. But in 1870 a Frenchman, named Gramme, solved the question of the most simple and economical form of a machine to produce electricity, which forms the principal subject matter of my lecture.

Mr. Gramme has been a remarkable instance of inventive capacity. Being employed on the repair of one of the magneto-electric (or so-called "Alliance") machines in France, he perceived that the true principle of producing an electric current had not been then practically applied; and with rare mechanical skill and an insight into electrical principles that amounted almost to intuition, he, with indefatigable zeal, succeeded in producing a dynamo-electric machine which was the first to yield an uniformly continuous current and without reversals by commutators.

After explaining a diagram of the Gramme machine, the lecturer said:—

It will be understood from this that the position of the poles is fixed though the ring rotates, giving off a constant stream of electricity in doing so.

I should here mention that in 1861 Signor Pacinotti, of Pisa, devised a machine somewhat resembling that of Mr. Gramme, but intended to convert electricity into motive force, and had Signor Pacinotti realised the value of the principle involved, and adapted his apparatus to the production of the electric current, we should now be ten years further advanced in the development of electric lighting.

Various modifications of Mr. Gramme's dynamo-machine have been made and brought forward as so-called improvements, some of which are shown in this Exhibition, but experience indicates that, whenever the simplicity of Mr. Gramme's invention

* Lecture at the Crystal Palace.

Digitized by Google

is departed from, a reduction of effect results compared with the power employed.

The experiments made by the Commission of H.M. Royal Engineers at Chatham in 1879-80 gave the following comparative results from the same horse-power:

	Luminuous Intensity.
Gramme Machines (average)	1,928
Siemens ,, ,,	1,428
Wylde ,, ,,	877

The experiments of the Committee of the Franklin Institute, United States, gave the following figures of merit:

Gramme Machine	(useful result)	38
Brush ,, (large type) ...	,,	·31
,, ,, (small type) ...	,,	27
Wallace Farmer Machines (average)	,,	13

The efficiency of any dynamo-machine for any particular class of work depends largely upon the proper proportioning of the masses of iron and the resistances of the wire in different parts of the machine.

It is owing to the fact that Mr. Gramme and others have unceasingly experimented on this subject, and also that more Gramme machines have been constructed than all the other types put together, that the remarkable efficiency of the latest forms on the Gramme principle has been attained.

Electric lighting is, of course, no novelty. In the old days, before the invention of these machines for producing electricity in quantity and economically, many inventors occupied themselves in devising electric lamps. Among the most earnest of these was Mr. Staite, who some of you may remember about thirty years ago exhibited a light from the top of the column in Trafalgar-square; and to whom I happen to have been a coadjutor in important electric lighting experiments in 1853, when the Liverpool landing stage and that part of the Mersey were illuminated by an arc lamp, the electricity for which was derived from a powerful series of galvanic batteries, which I need not tell you were neither suitable nor economical for commercial purposes.

Arc Lamps.

The various forms of arc lamps have all until recently had the relative position of their carbons regulated by the current transmitted, and in practice when this is done the adjustment comes into play a little too late and continues a little too long, giving rise to the frequent and considerable variations in light noticeable in this class of lamps. In a lamp invented by Mr. Brockie, and which forms one of the exhibits of the British Electric Light Company, the regulation is mechanical and periodical, and not in any way dependent upon any irregularity of current or in the consumption of the carbons.

Although the small incandescent lamps are so much more pleasant and steady in their light, and are undoubtedly more suitable for domestic purposes, the arc lamp possesses considerable advantages for many purposes, such as lighthouses, lighting large spaces, &c. The Brockie lamps have been in use for a long time at Cannon Street and other railway stations.

Incandescent Lamps.

Electric lamps for giving light by the transmission of the current through carbon in a vacuum were devised nearly forty years ago, but it is only during the last two years that they have been introduced in a practical shape.

The first desideratum in such lamps is a perfect vacuum, and the next an uniform conductor inside. The conducting filament, as a rule, is made from some vegetable fibre, which is carbonised by various processes. Strips of parchment, bamboo shreds, Turkey grass, and cotton thread have been employed by various inventors.

In the example I show you *bass* is the material, from the inner lining of the bark of certain trees. There have been many doubts expressed about the duration of such lamps, but this lamp is one among many of which a careful record has been kept. It has been used at one of our clubs for many months, and has been lighted for 1,860 hours.

If the particles forming the carbon filament of an incandescent lamp are homogeneous—that is, if the substance is pure, the density uniform, and the atoms evenly distributed—then the electrical motion transmitted does not produce irregular vibrations that would tend to disintegrate the filament. In such cases I see, theoretically, no limit to the endurance of the internal conductor provided the vacuum is perfect and excessive currents are not passed through such as would raise the temperature to the point of vaporising the carbon. Lamps of this class are now made to give even 500 candle-power.

Electric lamps have been worked from a Gramme with a length of over four miles of wire from the dynamo machine. It is obvious from this that one distributing centre would, if necessary, cover the supply to the greatest part of London, and that one distributing centre would suffice for every other city or town in the kingdom. As an instance of practical application the British Electric Light Company lighted up the Yacht Club and the Scottish Club with incandescent lights nearly a year ago, the distance being about ⅓ mile, and other incandescent lighting has since been added from the same centre.

On the subject of cost and convenience, as compared with the employment of gas, I may mention that the space required for an electric light generating station would not be one-twentieth of that needed for gas works, light for light, and that the conducting wires would cost very much less than the gas pipes, while the soil of the streets would not be contaminated, and there would be no risks of explosion either in the buildings or streets.

I now come to the use of Gramme machines for the transmission of force. In many cases where steam or other engines cannot conveniently be used on premises, a Gramme machine can be utilised to turn sewing machines or other apparatus by having a wire in connection with some central station where dynamo machines are driven to produce the current. For instance, at the British Electric Light Company's premises in Heddon-street the blast for a number of blow-pipes is required at the top of of the building in the rooms where the incandescent lamps are made, and the bellows are worked by a small Gramme machine on that floor, which is connected by a wire to a Gramme driven on the basement by the engine, thus obviating the difficulty of working the bellows by means of a long belt or other gearing through the intermediate floors.

In the south of England, where a district formerly arable but now mostly pasture land is intersected by a number of streams with many disused water mills, arrangements are being made for a railway of over thirty miles long, to be worked by means of electricity generated by Gramme machines driven by the otherwise waste water power.

PHYSICAL SOCIETY.—May 20.

Professor Fuller in the chair.

Professor W. Chandler Roberts, F.R.S., communicated the results he had obtained in repeating the experiments of M. W. Spring, Professor of the University of Liege, on the union of finely divided particles of metal by pressure. M. Spring had shown that at a pressure varying from 5,000 to 7,500 atmospheres, metallic filings may be united into coherent discs. Thus, at a pressure of 6,000 atmospheres, bismuth filings may be united into a disc, which has a crystalline fracture and a density which is identical with that of the metal cooled from the molten state. Zinc, again, also a very crystalline metal, will weld into a disc at a pressure of 7,000 atmospheres, and the metal will even "flow" into cracks between the die and the collar surrounding it, just as in the experiments of M. Fresca lead "flowed" under similar circumstances.

Professor Roberts had repeated and confirmed many of the experiments of M. Spring, whose more recent results are of special interest, as he has shown that if filings of bismuth, lead, and cadmium be *mixed* in suitable proportions, such, for instance, as in Wood's alloy, and if the mixture be submitted to a pressure of 7,500 atmospheres, an *alloy* is obtained which will actually fuse at 70 deg. C., the true fusing point of Wood's alloy being 632 deg. C. Professor Roberts showed to the society an alloy he had prepared which melted below 100 deg. C., although of the constituent metals the lowest melting point is 230 deg. C., and he pointed out the great interest both to the physicist and metallurgist of M. Spring's results.

Mr. Lecky gave the results of tests of Mr. Bennet's cell (described at the last meeting) made by Professor Guthrie. The electromotive force was 1·14 volt, the internal resistance 0·8 ohm, but both quantities vary under certain conditions.

Professor Macleod also gave the results of tests made by him. These show that the cell rose in E.M.F. from 1·005 volt on charging to 1·213 volt after standing three days. The internal resistance was then 1·007 ohm.

Mr. C. V. Boys then exhibited an improved form of his vibratory meter for measuring electric currents, and specially designed for electric lighting purposes. He has applied to the form formerly shown to the society the contact-making device employed in Hipp's electric clocks, which, though imperfectly adaptable to the clocks, is perfectly adaptable to the meter. The force is proportional to the displacement. No sliding contacts are employed. Mr. Boys also explained some other plans for current meters, one of which he believes to be the final form for practice, and which, besides being remarkably simple in construction, is free from the objection of being tampered with by means of extraneous magnets. In reply to Professor Foster, he stated that self-induction does not disturb their action.

ELECTRIC LIGHTING BILLS.

The promptitude with which the parliamentary committee on electric lighting Bills have arrived at their decisions and issued their preliminary report augurs well for the prospects of the new light. Notwithstanding the strong and combined opposition of the gas companies, the committee give expression to opinions which practically disregard such opposition altogether. The promoters of electric lighting enterprise may be congratulated on the times being favourable to their schemes. Vested interests of every description are at this moment in bad odour; and especially is this the case with respect to the two great corporations which have long possessed the monopoly of supplying us with water and with gas. The report of the parliamentary committee, as well as the Bill introduced by the President of the Board of Trade, are undoubtedly coloured by this prevailing sentiment, though neither can be accused of intentional unfairness or injustice. It is in their changed attitude towards the sacred rights of monopolies, rather than in any disposition to confiscate those rights, noticeable in the proposed legislation, that we find assurance of a fair field for the electric light. If it obtain none of the favour conferred upon similar undertakings of the past, it will at least escape some of the hindrances which competitors hitherto have had to confront.

On the whole, the resolutions of the select committee are fairly satisfactory, although in one or two respects they are not likely to go unchallenged by both the parties interested. The Board of Trade, it is suggested, should have two classes of powers for granting leave to electric lighting undertakings—the one when the consent of the local authorities is forthcoming, the other when it is not. In the first case the license may be granted by the Board itself for a term of five years, renewable at the end of that period; in the second case parliamentary authority must be obtained—presumably to override the objection of the local authorities. No limit is named for the operation of the provisional order obtained through Parliament, but as purchasing powers are granted at the expiration of fifteen years, that, presumably, is the period contemplated as the consequence of a victory over the local authorities where they oppose the scheme.

Various resolutions deal with the powers conferred for the breaking up of streets, the keeping of separate accounts where the light is supplied by local authorities, and with the control over the wires. It is satisfactory to observe that overhead wires are forbidden except with the consent of the local bodies; but in the event of their consenting to or themselves erecting overhead wires proved to be dangerous, or "likely to become dangerous to the public safety," an order directing their removal may be obtained from two justices of the peace. As a nominal warning that danger may be incurred, this provision counts for something—but not for much. The difficulty of proving the actual or possible danger of that which in the first instance has been thought perfectly safe is obvious; and to suppose that private individuals are ever likely to raise the question against public corporations is contradicted by all our experience. Wires of this kind are either dangerous or they are not, and it would have been better to have expressed a decided opinion one way or the other. Resolution 12, however, which deals with this matter, may prove salutory, not, perhaps, so much because of its penal as of its premonitory character. The erectors of overhead wires cannot say that they have not been warned.

The resolutions relating to purchasing powers and to the gradual extinction of gas interests will provoke the chief opposition. They are numbered respectively 8 and 10; and it cannot be denied that the provisions here set forth are open to a good deal of criticism from whichever point of view they are regarded. Both are impolitic, for the one will unnecessarily exasperate the gas interests, and the other will not encourage electric enterprise. Number 8 reads as follows: "That where it has been proved . . . . that any area . . . . is sufficiently supplied with electric light, and that the supply of gas in such area *has ceased* (the italics are ours) *to be remunerative*, the Board of Trade be empowered to make an order relieving, either wholly or in part, any gas authority from being compelled to supply gas within such area." Nothing but extreme haste will excuse such an extraordinary proposition as this. It cannot be seriously supposed that any gas company will allow itself to be slowly superseded, and to continue a lingering existence until it "ceases to be remunerative," in order that the Board of Trade may formally give it leave to die. It is not our province to supply the gas companies with arguments; and indeed on this point they have no need of our assistance. They must be prepared to face fair competition; but to press upon them an obligation such as that set forth in Resolution 8 is to provoke them into assuming an attitude which might result in there being no competition whatever. The monopoly of the gas companies is coupled with obligations; and to enforce these obligations to the last expiring gasp while deliberately invading the monopoly is simply impossible. To attempt it is to provoke defeat, and we are persuaded that the promoters of electric lighting have not knowingly countenanced

Digitized by Google

this proposition. They are prepared to enter competition on equal terms; but they are well aware that to seek for terms unduly favourable to themselves would be the surest way of getting no terms at all.

On the other hand, Resolution 10, dealing with the conditions of purchasing private electric lighting undertakings after fifteen years—as set forth in Resolution 9—is of doubtful fairness to the promoters. The value of the land, buildings, works, plant, and so forth, is to be taken into account when the local authorities choose to exercise their compulsory powers of purchase "at the end of fifteen years, or at the end of any subsequent period of five years," but—and here comes in the hostile sentiment to which we referred at the outset—"without any addition in respect of compulsory purchase, or of goodwill, or of any past or future profits, or of any similar consideration." The shadow of Mr. Cross's Water Bill is evidently over this resolution; we are going be very farseeing, very virtuous, and very clever in all future concessions—at least, so thinks the President of the Board of Trade. But it is possible to be over clever, and we think this is an instance of the kind. For thrice five years only are the proprietors of electric lighting to reap the fruits of their enterprise; at the expiration of that term their stock in trade may be bought at a valuation, and their trade itself appropriated. The one sole merit of this form of prospective confiscation is that it gives at least a fifteen years' notice. The drawback is, that we have no experience of how it will work; but we can make a good guess. It will increase the price of the commodity and lower it in quality. One of the resolutions provides for the fixing of a "fair price" at which the light shall be supplied. Unless the arbiters in this case are to proceed somewhat on the same lines as do the Commissioners of the Irish Land Courts, a "fair price" must take into account the contingent extinction of interests. Exorbitant as are the prices charged by gas and water Companies we have at least been spared the extortions of a limited monopoly bound to make all its profits in a given number of years. Neither in the interests of the public nor in those of electric light promoters can we approve of this resolution. The committee stood adjourned to the 8th inst., when they were to consider amendments not controvening the principles of the resolutions at which they have arrived. We shall be curious to learn whether the substance of Resolutions 8 and 10 are maintained as "principles."

ATLANTIC CABLES.

We have before us a circular addressed to the shareholders of the Anglo-American Telegraph Company by an ex-stockholder. Artemus Ward told us that there remained still a "good deal of natur in man," and we might ask, without disrespect to ex-stockholders, Why should an ex-stockholder be so very anxious to influence the actual shareholders? He tells us that he is safe out of the concern, and yet he is generous enough to spend his means in printing and publishing circulars to those who yet have shares to sell. We have lived long enough in the world to look with suspicion upon such actions, and we doubt not that if we could see behind the scenes, "Ex-Stockholder," or someone connected with him, has hopes of making something out of this circular.

It is extremely difficult in most cases to trace misstatements to their sources; they are generally verbal and fleeting, but here we have something tangible, and we can distinctly say the statements are utterly false. The shareholders are told to sell out, and the arguments for this course are derived from a consideration of, as we say, false statements. We do not intend to discuss the whole of this circular, but we may say that, from investigations we have made, a direct denial is given to the statement that certain shareholders have been "refused all information." That the receipts are not contingent upon the company maintaining *four* cables. That the fourth cable is not hopelessly abandoned in the bed of the ocean. That the most eminent electricians do not estimate the life of an Atlantic cable at ten years only. The statements we have referred to are in this circular just the opposite of true. We hear that the "Scotia" has actually picked up one end of the cable in question, and is going on with the work of repair. That surely is not hopeless abandonment. A large number of our readers are interested in cable work and cable property, hence it will not be deemed superfluous for us to have called attention to this circular, and to have pointed out how unworthy of credence it is. Competition cannot well be avoided; it would be well in some instances if it could, and instead of attempting to hamper the management it would be well if some shareholders gave a little more support to those who have their interests in hand. The actions of outsiders should be critically examined, and great care taken not to accept views that are urged by those whose interests are not identified with those of the company.

CORRESPONDENCE.

WHAT IS ELECTRICITY?

Gravitation.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The subject of my present communication is the intimate connection which subsists between molecular manifestations of force—which I have attempted more especially to define in the propagation of light—and terrestrial and universal gravitation.

Every portion of matter attracts every other portion of matter, and the stress between them is proportional to the product of their masses divided by the square of the distance. Such is the law of gravitation, and it is owing to the influence which this universal force exerts, according to accurately-defined laws, upon the heavenly bodies, that their proper motions in relation to each other and to systems are determined; and inasmuch as the force is propagated from one atom to another, from one celestial body to another, each increasing in magnitude and accompanied by stress, we are assured that the generally-accredited doctrine of closed circuits of force cannot exist even in the universe; that the motion of the largest masses is continuous with that of the infinitesimal atom; and that the motion of one mass in the universe cannot occur without propagating its motion, according to the well-defined laws of motion, at least to the other units of the same system.

I shall endeavour now to prove

1st. That universal gravitation is identical with the universal exhibition of magnetic force.

2nd. That each celestial body is a mass of matter which has been condensed by the operation of force from without.

3rd. That after a mass has undergone the full process of condensation, it continues to receive from the sun of the system in which it moves a constant supply of indestructible force, the counterpart of which it returns in the form of stress to the sun.

4th. That every celestial body is charged according to its capacity with this force, which is productive of its mechanical

Digitized by Google

life in all its varied phases, and that after performing its work upon the mass it is projected into interplanetary space, to effect work upon other bodies with which it comes into contact.

5th. That the work done upon a mass is effected through the medium of one grand physical law, by means of which each form of matter exerts a *special directive* influence upon force.

6th. That this law manifests its power on the masses by the inclination of the planets on their axes, and is, in fact, the first element in the production of rotation; and then in their orbital motion, whereby the seasons and the various phases of life proper to each are maintained. It is perceived artificially in the atoms of matter by the inclination of bodies when suspended in the field of an electro magnet; in the vegetable kingdom of nature it determines the mode of growth; the production of all shades of colour; and of every variation in form; whilst in the animal world it is exhibited in causing the circulation of the blood; in determining variations in the shape of the blood corpuscles; in differences of species; in the selecting from the plasma of the blood the various elements essential to the formation of each particular description of tissue; in the moulding of those particles into cells under centripetal and centrifugal force; in the evolution of the senses; in the formation of those beautiful spiral ganglia which are formed on the roots of the nerves of sensation, and, in fact, in the carrying out with the most perfect integrity, in accordance with the will of the Almighty architect of the universe, the proper manifestation of every vital phenomena natural and acquired.

I base my theory upon the following data:—

1st. That the celestial bodies are masses of matter, rotating upon their axes whilst moving through space, by which motions momenta are generated in them in directions according with their motions.

2nd. Corresponding motion is imparted to the medium in which they are moving.

3rd. That as we have to do with spheroidal bodies, the motion manifested over each polar hemisphere must assume the form of vortices; that these vortices are right and left-handed according as they are situated to the north or south of the equatorial line, the apices being at the magnetic poles.

4th. That similar vortices of force are extended from the magnetic poles into space, the apices of which are also at the magnetic poles.

5th. That as the force is extended into interplanetary space it becomes more diffused, but is always projected in a direction which varies with the direction of the moving mass, except in so far as it is interfered with by other force emanating from some other body.

6th. That by stress this force projected from a mass must attract force to the mass from without, the direction of which must be opposite and the amount equal to that ejected.

7th. That as these vortices of force depend upon the motion of a mass, it is evident they could not exist if the mass were at rest; *they are consequently secondary to the force which has imparted motion.*

8th. Terrestrial gravitation acknowledges that the celestial bodies, like the earth and its moon, perform their orbital motions owing to force which is imparted from the sun of the orbits in which they move. We, therefore, find that the moon is dependent upon the earth, the earth upon the sun, and as the sun is moving upon the same principle in another but much larger orbit, we have reason to believe that its initial force must be derived from the sun of that system.

9th. For the purpose of substantiating this principle it will be well to confine attention to the sun and the earth. We have, then, to deal with two masses of matter which are rotating upon their axes and in their orbits in the same direction; and further these movements are performed in a medium, the density of which decreases as the distance from the mass increases.

10th. We have next to consider the influence of that enormous force which the earth receives from the sun. With reference to this a recent writer, Dr. Young, expresses it thus:—"If the earth could be suddenly stopped in her orbit and allowed to fall unobstructed towards the sun, under the accelerating influence of his attraction, she would reach the centre in about four months. I have said if she could be stopped, but such is the compass of her orbit that to make its circuit in a year she has to move nearly 19 miles a second, or more than fifty times faster than the swiftest rifle ball; and in moving 20 miles her path deviates from perfect straightness by less than $\frac{1}{8}$ of an inch, and yet over all the circumference of all this tremendous orbit the sun exercises his dominion, and every pulsation of his surface receives its response from the subject earth." And again, with the object of showing the enormous attractive force which the sun exerts upon the earth, I find from some calculations by Mr. C. B. Warring that "if we imagine gravitation to cease and to be replaced by a material bond of some sort, holding the earth to the sun and keeping her in her orbit, and suppose this connection to consist of a web of steel wires, each as large as the heaviest telegraph wires used (No. 4), then to replace the sun's attraction these wires would have to cover the whole sunward hemisphere of our globe about as thickly as blades of grass upon a lawn. It would require nine to each square inch." Now, this enormous force, viz., that which is due to the action of the sun alone is bound to pass through the mass of the earth subject to the laws of motion, and then to be projected as indestructible force into interplanetary space, increased momemtum having been imparted to it by the motion of the earth.

11th. I have already pointed out that the motion of the earth gives rise to momentum in a direction according with its motion, and that this force is extended into interplanetary space, originating vortices in a direction according with the motion of the earth. It will be perceived that the force which is constantly being impressed by the sun upon the earth is in a direction exactly opposite to the motion of the earth; consequently we have the phenomena of force being projected from the earth from both of these sources, and the formation of two vortices at each magnetic pole, the apices of which are in the same situation, but the motions of which are in direct opposition the one to the other. Now, here we have a phenomenon very difficult of apprehension, but perfectly capable of being explained under the influence of mass motion in interplanetary space as above described.

12th. I pointed out in *The Electrician*, June 25th, 1881, that the phenomena exhibited by iron filings under magnetic attraction and repulsion are to be explained by force acting in helical lines, and so far as I have been able to determine, those phenomena could not be represented by force moving in any other manner. It will now be perceived how completely these phenomena which I have demonstrated by means of artificial magnets—*vide The Electrician*, June 25, 1881—accord with the more extended apprehension of the effects of the earth's motion through the lines of force which reach it from the sun, and how perfectly the development of terrestrial magnetism as here set forth agrees with the explanation I was then able to advance as to the cause of artificial magnetism.

13th. In the paper I read at the Physical Society in June, 1880, to which I have referred already, I expressed the opinion that the earth's rotation was due to reaction, and I compared the earth to Hiero's steam engine, but it will be perceived that the force of the sun extends right over the magnetic poles alternately, and that the motion of the earth causes this force to be gathered into vortices at the magnetic poles; vortices which correspond with those described in paragraphs 3 and 4, with the exception that their direction is to the west instead of to the east. Now, these vortices, which result from the force of the sun by the third law of motion, must be designated the action of the sun; whilst those which occur in the opposite direction, and which are caused by, and accord with the motion of the earth establish the consequential reaction. *We thus perceive the principle upon which stress in the earth is the resultant of the force of the sun upon the earth,* and at the same time the cause of those helices of force which are developed at the magnetic poles of the earth, the counterpart of which *in section* may be observed by means of iron filings emanating from the poles of a magnetic bar, and much more completely by the motion of the needle point magnet when placed on the end of a fixed magnet and subjected to the action of a like pole of another magnet

Digitized by Google

pushed slowly towards it (*vide The Electrician*, June 25, 1881).

14th. It is also evident owing to the motion of the earth—of which it is the expression—that the force of reaction extends in a helical direction from the magnetic poles of the earth to the line of the ecliptic, and thence to the sun, being the concomitant of the force of the sun throughout; and, further, that the two helical momenta, influences, or lines of force around the north polar hemisphere are left-handed, whilst those round the south pole are right-handed, that is, placing action before re-action. The entire stress of these forces upon the mass of the earth, and its immediate polar surroundings, is capable of being illustrated mechanically in the following manner:—A cylinder of wood, 12in. long by 5in. wide, was turned into a sphere and two half-spheres—with the exception of a central connecting rod—the sphere being in the middle. Two helical grooves were cut on the surface of the sphere, starting from a point equidistant from the half-spheres, one of these grooves being right, and the other left-handed. These grooves were then continued in the same direction, over the half-spheres. A hole was then bored through the sphere, commencing from the point of departure of the two grooves, and another hole at the termination of each groove on the edge of the half-spheres. Four cords—two red and two white—were then run through the central hole and fixed. One cord of each colour was now drawn to the right, and the other two to the left; by rotating the apparatus upon its axis the two cords passing to the right were wound in a left hand helical direction round one half of the sphere, and then, after being fixed by a piece of twine to the bottom of the groove, were continued onwards in the same direction over the adjoining half sphere to the edge of which they were fixed. By the same movement the other two cords had been wound in a right hand helical direction round the half spheres to the left, and were then fixed in the same manner. It will be perceived that if the two red cords represent the force of the sun upon the earth, and the two vortices beyond the poles, the white are representative of the motion of the earth, and of the vortices formed by that motion beyond the poles. The red cords are indicative of action, and the white of reaction. It will be further perceived that the two forces are moving into each other upon the principle of the male and female screws, and are significant of magnetic attraction.

15th. I think I have now made it evident, first, that the force engaged in the production of universal gravitation is helical and precisely of the same character as, and, in fact, identical with magnetic force. Second. It must be evident, if I have stated the facts in accordance with the laws of motion, that each celestial body is a mass of matter which has been compressed from without; for the force of the sun is applied over every portion of the earth's surface in a helical direction. Third. That after a mass has undergone the full process of condensation from such cause it continues to receive from its sun a constant supply of force, the counterpart of which it returns to that sun. Fourth. That every celestial body is charged, according to its capacity, with this force, which is productive of its mechanical life, and is then projected into space to effect other work upon other bodies with which it comes into contact. Fifth. The existence of a physical law, by means of which each form of matter exerts a special directive influence upon force; and that this law is the primary element in the production of motion and rotation.

16th. The question next arises as to what is the cause of two magnetic bodies, each of which is attracting the other with such an enormous force—as is known to exist between the sun and the earth—performing their proper orbital motions without appreciably approaching each other? The answer, of course, at once suggests itself—the development of the centrifugal force; and this is perfectly true. But I submit that the theory now put forth enables us to perceive the *cause* of these things being as they are; that is, why one force, which may be called a repellent force, is caused to attract a mass in exactly the same proportion as it repels; and why the centrifugal force is evolved by the same force under the same principle—the principle which I illustrated in my letter on the propagation of light—by means of a shot placed between two helical wires, and kept rotating upon its axis *in the same spot by the equal motion* of the two wires (*vide The Electrician*). We are thus assured that this one principle pervades the universe, manifesting itself—first, in the propagation of light, and then in universal gravitation, and subsequently we recognise it as the cause of every natural phenomenon, extending itself even to the evolution of vegetable and animal life, nay more, to the development of the mental faculties, for these, in common with every other phenomenon, must be influenced by the character of the matter out of which they spring.

When we realise the fact that all these results are obtained from the directive influence which matter exerts upon force, surely we can only be struck with admiration at the perfection of the mechanism; for it is self-evident that matter and force were created subject to this law, and that with the express object of developing all those phenomena with which we are now so imperfectly acquainted.

In my next letter I hope to make application of this principle of helical force to the physical changes which are known to occur in bodies under variations of temperature.—Yours, &c. RICHARD C. SHETTLE.

Reading, May 26th, 1882.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Johnstone's article shows nothing more than what every schoolboy student of electricity knows, viz., that currents (*sic*) of electricity flow in a fixed direction, and cannot vary except by reversion of the poles.

The denial of the existence of *static induction* is totally unsupported; no proof is given of the current passing *through the glass* of the Leyden jar. The "bending of the two gas flames in one direction" does not *disprove induction*; it only shows the passage of a current, and is no evidence of *electrical matter* passing through the glass of the jar.

The crucial experiment intended to establish the idea of *electrical matter* is a myth. The interference with the ready generation of a current through the jars by the substitution of a pointed wire for the orthodox knob produced only the effect readily surmised without experiment at all, namely, a tardy and interrupted current, due to dispersion through the pointed wire and imperfect charging, owing to the resistance arising from imperfect connection within the jar.

Static induction is not touched in the "experiment," not is the question of *force or matter* affected by it, excepting that such a feeble support of the *latter* idea is a negative argument in favour of the former.—Yours, &c.,

Redhill, Surrey. D. HARBORD.

NOTES AT THE CRYSTAL PALACE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following notes, made by a perfectly impartial observer at the Crystal Palace, may prove interesting to some of your readers:—

(1). That among all the arc lights the "Pilsen" appeared to be undoubtedly the steadiest.

(2). That the lamps of Messrs. Siemens Bros. are entitled to take the second place, and that both systems are far in advance of their other competitors.

(3). That Notes 1 and 2 are strong evidence in favour of the differential system, to some extent similar in both these lamps.

(4). That the Brockie lamp shows to much better advantage there than it did in Liverpool, where it had made a very bad impression.

(5). That the Jablochkoff can still compete with the great majority of systems, notwithstanding the fact that its death-knell was supposed to have been sounded at Paris.

(6). That the writer was extremely disappointed with the performances of Mr. Crompton's lamp.

(7). That all users of the light should avoid the Brush;

Digitized by Google

their machine room, though brilliantly lighted, was extremely trying to the sight.

(8). That the Joel semi-incandescent light is extremely useful, and for certain purposes would be without a rival; when seen by the writer not the slightest flicker could be observed. It is said to consume about half a horse-power per light, requiring a current of 45 ampères through a resistance of about ·15 ohm, and giving a light equal to about 250 to 300 candles.

(9). That among incandescent lamps Swan, by making his carbons carry a current of 1·34 ampère, produces a light far superior in quality to any of the others, and that if at this temperature his lamps have a lasting power equal to the other systems it follows that the quality of the carbons must be better and the light more economical, but on this point no evidence is forthcoming.

(10). That the shape of Maxim's carbon is the best for giving an equable light, but that the price of the lamp is absurd.

(11). That the horse-power required to produce a very moderate degree of illumination in the rooms of the Domestic Electric Lighting Company is appalling to contemplate.

(12). That Messrs. Crossley Brothers' exhibit of one of their half-horse nominal gas engines driving a Siemens dynamo feeding ten Swan lamps is very interesting, and calculated to give a fair idea of the power required; the engine indicates $1\frac{1}{2}$ h.-p.

Dynamo Machines.

(1). The array shown by the Brush Company is most imposing, and their workmanship leaves nothing to be desired; their very high E.M.F. causing them to spark considerably at the commutators.

(2). That the British Electric Light Company have adopted the flat or oval section for the field magnets of their Gramme machines in preference apparently to the original round section.

(3). That it speaks volumes for Siemens machines that they are used by so many independent exhibitors.

(4). That it seems peculiar to find most of Siemens's new machines are upright, and most of the British Electric Light Company's new machines are horizontal.

(5). That we should like to know how long it would take for the power saved in Edison's machines by using his large magnets to pay for the extra material, and that we hope very few people will be so hasty as to pay £200 for one of them.

(6). That the Burgin machine will probably stand more wear and tear than most of the others, but is shrewdly and naturally suspected of absorbing rather more than its share of power.

(7). That the price of all dynamo machines of the present day is altogether too utter to tempt the majority of persons to whom the light would be otherwise an advantage.

Telephones.

That it is utterly impossible to find anything but the Gower-Bell, which is the more annoying as this instrument is *not to be compared* for efficiency with the Blake and Bell combination, which we have in our offices in Liverpool.—Yours, &c. G. A. Moore.

[We insert this letter more to give a specimen of the conclusions come to by an outsider than for its intrinsic value. It may, however, be well to say that, unless the arc lamps were burning the same kind of carbon, and not, as was really the case, some lamps burning the very best French carbons, while others were burning ordinary English made carbons, such a rough and ready test is wholly misleading. Change the carbons, and the chances are you completely alter the performances of the lamps. —Ed. *E.*]

NEW LAMPS, COMPANIES, &c.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: It would be very interesting to those who are following the history of electrical inventions if the promoters of the Self-Generator, Duplex, and Fyfe Main Companies would vouchsafe answers to the following questions:—1st. What is the self-generator for which the sum of £80,000 in cash and £40,000 in shares is asked—is it a dynamo machine, or is it a galvanic battery? again, 2nd. What is the Duplex system? where and how is it employed? and can it be seen at work? 3rd. In what points does the Fyfe Main lamp differ from the Crompton lamp as exhibited by Messrs. Crompton in Paris?—Yours, &c., X. Y. Z.

London, E.C., June 8, 1882.

A TIDAL WHEEL FOR MOTIVE POWER.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: While speaking to Mr. Cannon, to whom I believe you are known, he mentioned that you had suggested the use of tidal rivers as a motive power by which electricity might

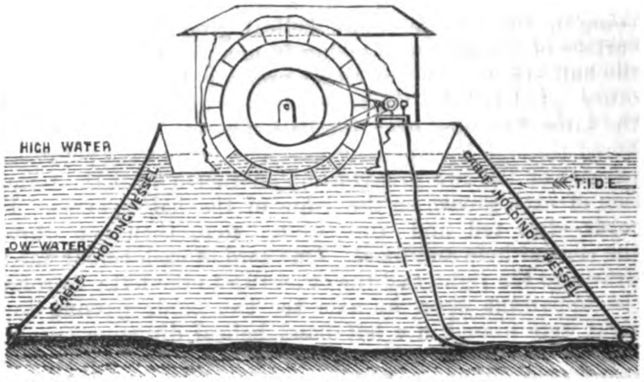

Fig. 1.—Water wheel for tidal rivers supplying current to Faure accumulators during the day. The accumulators to be used at night for lighting purposes.

be stored in Faure's secondary batteries, and used for lighting and other purposes. I take the liberty of enclosing a sketch of a simple yet effective means by which I believe those ends could be attained. You are at liberty to make whatever use you like of it.

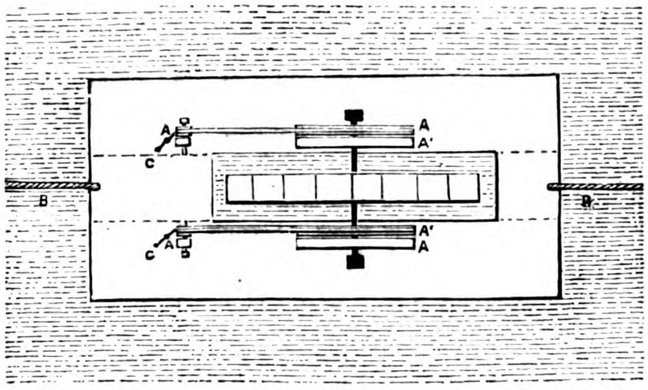

Fig. 2.—Ground plan of water wheel. A A, loose wheel and pulley; A' A', fixed wheel; B, cable for holding vessel; C C are levers for moving the driving belt from the loose to the driving pulleys of the dynamo machine which is supposed to be placed between C C.

You will see on referring to the ground plan that on the tide turning the bands are changed, so that the small band wheel of dynamo machine runs always the same way.

I should be pleased to hear your opinion meantime.—Yours, &c., Vincent A. Wraight.

2, Cannon-street, May 19.

Electric Light on a Yacht.—The yacht "Namouna," belonging to Mr. J. Gordon Bennett, of New York, has been fitted with 120 Edison B lamps of eight candle-power. The dynamo is driven by a special engine supplied with steam from either the main boilers or the donkey boiler, the exhaust steam being delivered either into the condenser or through the side of the vessel. The lamps are arranged in the cabins and saloons, engine room, &c., and also in the shaft alley. The lamps in the engine room are furnished with long flexible conductors, so that they can be carried out, and the machinery examined by their light.

THEORY OF MAGNETO AND DYNAMO MACHINES.

XV.

In last week's article the letter N was used in two senses, by inadvertence. Its original sense was the number of lines of force passing through any contour—or the potential of the contour—but last week it was also used to signify merely the number of turns of wire on a coil. For this last, therefore, we must devise a fresh symbol; n is already at work and ν is unsatisfactory, suppose we try K; and let us proceed to re-write the equations expressing the resistance, the E.M.F., the current, and the power, concerned in a revolving coil of diameter D; which contains M grammes of wire of specific resistance r and specific gravity ρ wound in K turns; and which is spinning n times a second in a magnetic field of intensity I.

And we will take this opportunity of putting those expressions into other equivalent and instructive forms, by introducing explicitly the thickness and length of the wire on the coil. Let the length be called l, and the cross sectional area of the wire a; then since $M = l\,a\,\rho$, and $K\,\pi\,D = l$, we have

$$R = \frac{l\,r}{a} = \frac{K\,\pi\,D\,r}{a} = \frac{M\,r}{a^2\,\rho} = \frac{l^2\,r\,\rho}{M}$$

$$E = n\,I\,K\,\pi\,D^2 = n\,I\,D\frac{M}{a\,\rho} = n\,I\,D.l$$

$$\gamma = \frac{n\,I\,M}{K\,\pi\,r\,\rho} = n\,I\,D\,.\frac{a}{r}$$

$$P = (n\,I\,D)^2\,.\frac{M}{r\rho}.$$

All these expressions are instructive if one takes the trouble to examine them. They show, for instance, that with a coil of given size the E.M.F. is directly proportional to the length of wire used, the current to its sectional area, and the power necessary to turn the coil to its bulk. Further, that the E.M.F. and the current are each simply proportional to the rate of rotation, the strength of the field, and the diameter of the coil; while the power is proportional to the square of these same quantities.

The units in which all the above quantities will appear if everything is measured in centimetres, grammes, and seconds will be absolute measure; but it is easy to get them into practical units.

To get E in volts you must divide the above expression for it by 100,000,000. To get γ in amperes you must multiply its above expression by 10. While to get P into horse-power you must divide by 7,460,000,000, if you please (*see* Art. XI.).

It may further be convenient here to record that for every horse-power running to waste 177·62 thermal units per second are generated.

We will leave the revolving coil for the present, but shall return to it, because it will obviously lead us up to the consideration of a revolving armature.

Turn back, now, to Art. IV., p. 118, and consider the wheel and rails of Fig. 1. If the axle moves with velocity v over a distance x, $V\,b\,x$ fresh lines of force are added to the circuit (V being the vertical intensity of the earth), and the *rate* of adding lines is $V\,b\,\frac{x}{t} = V\,b\,v$; hence this is the E.M.F. tending to produce a current.

In the pendulum of Fig. 2, the rate of adding lines of force $\left(\text{or}\,\frac{dN}{dt}\right)$ is evidently $\frac{1}{2}\,H\,l^2\,\frac{d\,\theta}{d\,t}$; so this is the electromotive force producing the induced current due to the motion. Similarly, the E.M.F. in the rotating disc, Fig. 3, or the revolving wire, Fig. 4, rotating in a field of average intensity I with the angular velocity ϵ, is $\frac{1}{2}\,r^2\,I\,\epsilon$.

All these are contrivances which will move when a current is supplied by a battery, and which will induce a current themselves when moved by hand. As motors we considered them before; as inducers of a current we consider them now.

In Art. VIII., p. 205, are two other contrivances, Fig. 6 and Fig. 7. In the symbols there employed, and on the supposition that the magnets may be treated as ideal ones, with the poles practically points, the E.M.F. of induction when they are turned by hand with angular velocity ϵ, or n times a second, may be written at pleasure in any of these ways:—

$$2\,m\,\omega\,n = \frac{m\,\omega\,\epsilon}{\pi} = 2\,m\,\epsilon\,\frac{s - a}{s} = 2\,m\,\epsilon \text{ vers } \theta, \text{ for Fig 6.}$$

and

$$2\,m\,(2\,\pi - \omega)\,n = \left(2 - \frac{\omega}{\pi}\right)m\,\epsilon = 2\,m\,\epsilon\,\frac{s}{a} = 2\,m\,\epsilon \cos\theta, \text{ for}$$

Fig. 7.

The angle θ, it will be observed, is the plane angle subtended by the radius of the trough at either pole. Now, the smaller this angle the better, whether we wish the thing to act as an electro-magnetic engine or as a magneto-electric machine. Hence, we can with advantage do away with all mercury troughs and other complexities, and construct the simplest possible of all magnetic motors by taking a round bar magnet, pivoting it at its two pointed ends, and letting a light rubbing contact rest against its middle. If it be now spun by hand n times a second (each of its poles being of strength m), a current will be urged from the middle to either end, with the E.M.F. $4\,\pi\,m\,n$. If, on the contrary, a current γ from a battery be sent in at one end (or both) and out at the middle, the magnet will begin to rotate, with the moment $2\,m\,\gamma$.

THE CRYSTAL PALACE EXHIBITION.

The Edison Exhibit.

Although we had heard much of Edison's light, few of us had seen it until the present year. True he made a grand display at Paris, but thousands who have now seen the light could not go to Paris. From the evening when the concert room was first lighted up before a select audience till the present moment the attraction of the Edison display has been one of the most prominent in the Exhibition. The designers of the exhibit, Mr. Johnson, the representative of Mr. Edison in England, and Mr. Hammer, the engineer, intended to make the exhibit attractive, and they have been successful, aided by Messrs. Verity and Sons, of King-street, Covent-garden, who designed and manufactured the ornate "electrolier," &c., in the Entertainment Court.

The exhibit comprised about 1,080 lamps, two-thirds of the lamps being of 16 candle-power, known as A lamps, and the remainder of 8 candle-power, known as B lamps. There were also a number of lamps of 32 and 50 candle-power, as well as lamps of various forms, of different kinds of carbon, with carbons arranged in various ways in the globes, specimens, in fact, at once interesting and instructive. The space set apart for the Edison exhibit was, we believe, considerably larger than that occupied by any other exhibitor at the Palace, and consisted of (1) The Entertainment Court, which was lighted by 250 lamps, arranged in every conceivable form, from the huge electrolier or basket of flowers, with its 99 lamps, down to the tiny lamp which might be run with a small battery or accumulator.

The application of the Edison lamp to artistic decorations and fixtures was shown on a large scale from designs, as we have stated, prepared by Messrs. B. Verity and Sons, of King-street, Covent-garden, by whom the work was carried out in a very able manner.

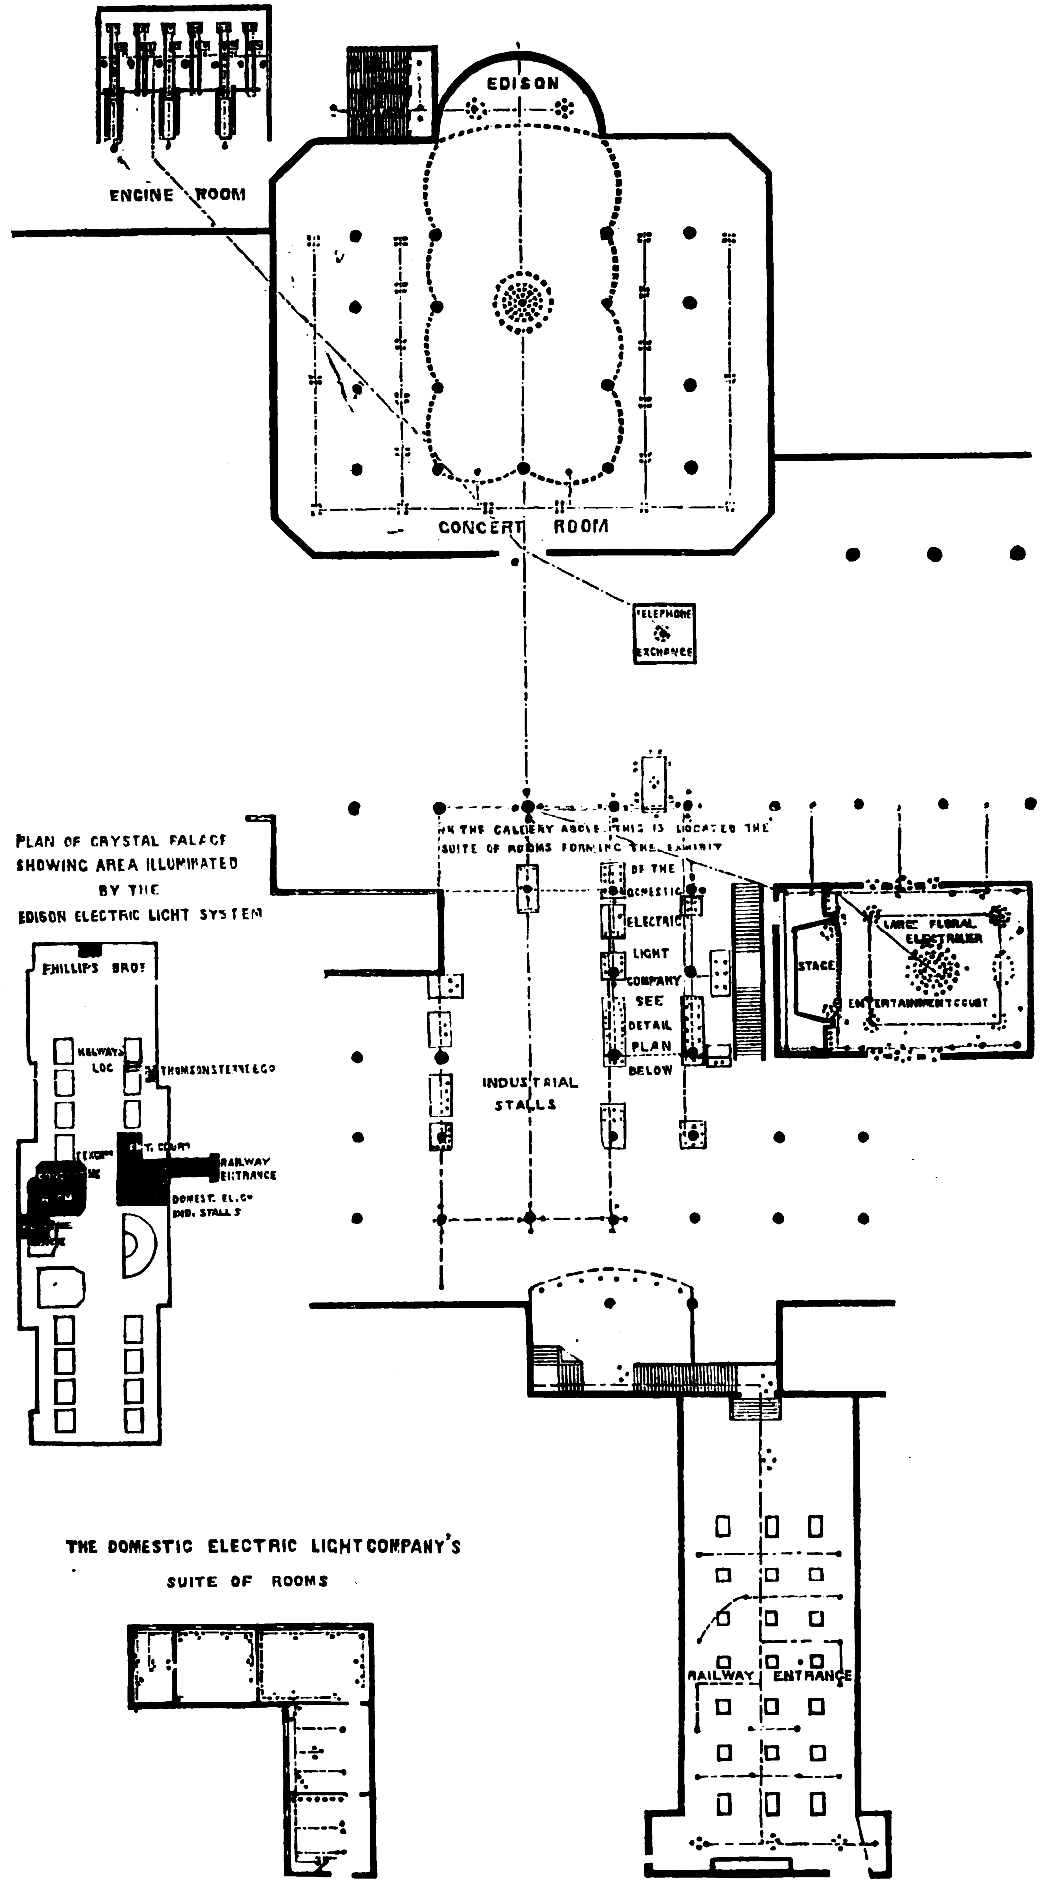
Besides several special features, such as stage footlights, hall lights, billiard lights, &c., the Entertainment Court contained a number of Mr. Edison's inventions in connection with telegraphy, the telephone, and phonograph, as well as many other valuable discoveries.

Many of the Edison exhibits were shown at the recent Paris Electrical Exhibition, and formed one of the chief features of interest there.

Next in importance to the Entertainment Court, which was one of the chief attractions to all sightseers, was the large concert room lighted with 240 lamps, hung in festoons around the galleries and a magnificent crystal chandelier, which alone contained 83 lamps, besides numerous small

Digitized by Google

chandeliers suspended underneath the galleries, while over the stage were suspended two handsome fixtures, thus afford-

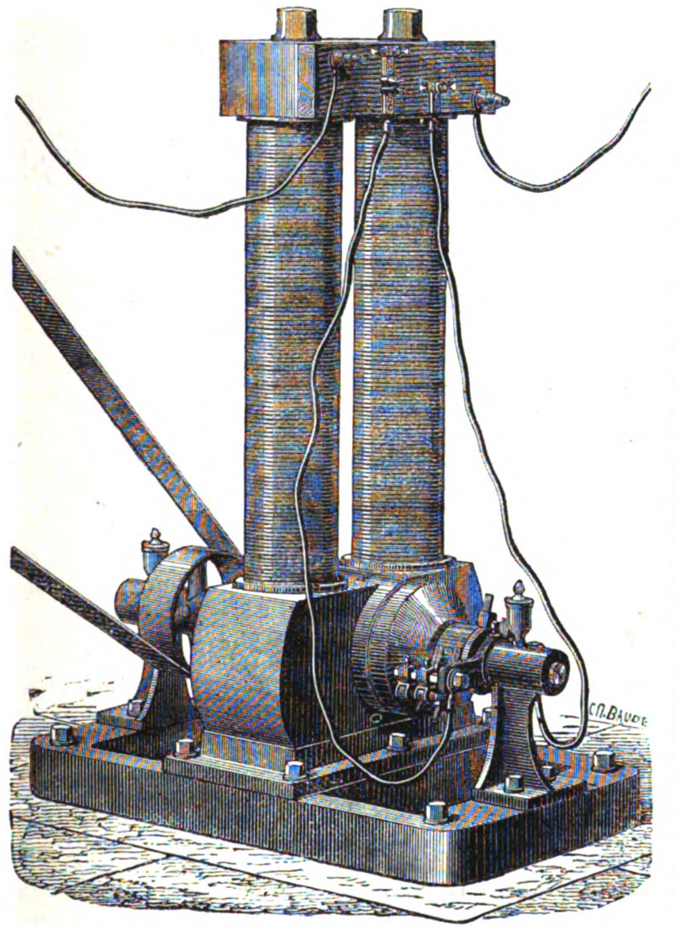


ing ample light for the orchestra. In front of the organ the name "Edison" was effectively displayed by means of 64

Digitized by Google

eight-candle lamps. Notwithstanding the size of this large room the lights employed were ample for a brilliantly soft illumination, and the appearance presented was superior to any effect which could be produced by means of gas, and probably arc lights, even under the best conditions, would fail to be so pleasant and agreeable. We must confess that the chandelier in the centre of the concert room always seemed to us one of the prettiest exhibits in the building.

The Industrial Court comprising the booths, stalls, &c., fronting the concert room and extending to the High Level Railway entrance was lighted by Edison lamps attached to the existing gas fixtures, and suspended in various ways. The archways leading from the London, Chatham, and Dover Railway to the Palace were effectively lit up, the lamps being hung from the ceilings. Visitors leaving the Palace would also observe the approaches to the Palace from the railway illuminated by Edison lamps, whilst in the railway station could be seen a single suspended lamp enclosed in a transparent globe showing forth the inventor's name.



Edison's Dynamo.

A most important feature was the lighting of the suite of rooms artistically furnished for the Domestic Electric Light Company by several firms of high standing. An opportunity was here afforded to demonstrate the application of the Edison incandescent light for domestic purposes. The lighting of these splendidly furnished apartments was very much admired, and added very considerably to the general attractions of this exhibit.

The shrubbery near the Entertainment Court was also lighted with lamps enclosed in glass globes containing coloured solutions, the effect of which was extremely pretty.

The Telephone Exchange, situate in the Grand Nave, was effectively lit by a huge æsthetic sunflower studded with small Edison lamps. Other exhibitors at the Palace were also supplied with Edison lamps, including Messrs. Phillips Brothers, whose stall in the gallery at the opposite end of the building under the large clock was lit from the Edison central station. The application of Kelway's electric log was also shown, with Edison lamps burning under water in a large tank, in which the apparatus was placed. Messrs. Thompson, Sterne, and Co., also exhibited a number of Edison lamps run by a dynamo driven by a Clerk gas engine.

The whole of the Edison lights exhibited in various parts of the building were under immediate and independent control, and might be raised or reduced as required, each lamp and each circuit being provided with an Edison protection plug, consisting of a piece of lead wire, inserted at each circuit, which melts at a low temperature and prevents any danger either from malicious or accidental contact or short circuiting of the wires. This method of protection is due, we believe, to Mr. Edison, and is one of very great importance, and plays a prominent part in the completeness of his system.

Not the least important and attractive feature of the Edison exhibit were the dynamo machines which were to be seen on the floor underneath the concert room. This plant consisted of twelve of Mr. Edison's 60 light dynamos, arranged in sets of four, each set driven by a 25 horse-power nominal Robey engine. The engines worked upon a counter shaft provided with friction clutches so that one or more machines could be thrown out of circuit without affecting the others. This plant was arranged in order that, in the event of the failure of one machine, or the stoppage of an engine, a margin of reserve could be at once called upon. The machines were arranged in multiple arc and connected with an Edison regulator, an ingenious device for regulating the strength and efficiency of the magnets of the respective machines. As was frequently done for the purpose of demonstrating the utility of this regulating device, an engine was stopped and the remaining engines brought up nearer to their maximum capacity, and the deficiency made good. This was done with scarcely any perceptible effect upon the light.

A good illustration of the facility with which the lights were controlled was shown in the concert room on the occasion of the course of lectures delivered there, during which time the whole of the lights were repeatedly put out at a signal given by the lecturer, in order to show upon a screen diagrams, &c., used for the purpose of these lectures, and although 150 lamps were thus extinguished and relit at frequent intervals during the delivery of the lectures, the operation had scarcely the slightest effect upon the lights in use in various other departments of the exhibit, and were manipulated without any communication being made with the engineer-in-charge of the dynamo machines.

The conductors used for carrying the electricity to the various sections of the exhibit consisted of two half-round copper conductors enclosed in an iron tube, and surrounded by an insulating compound of very high resistance. These conductors are similar to those employed by Mr. Edison in New York (which have been previously illustrated by us), where some thirteen miles have just been laid in the streets, and which, after having been covered up several months, test perfectly.

It might also be added that these Edison electric tubes, as they are called, are employed on the Holborn-viaduct for distributing the electrical current to the various shops, hotels, &c., along the Viaduct from Old Bailey to Hatton-garden Circus.

It may be pointed out that the Edison exhibit was one of the first ready. We believe the Electric Light and Power Generator Company was actually the first to light up, and was quickly followed by Edison. We are quite sure that many of our English firms might with advantage copy a little of the energy that has been thrown into this exhibit. It reminds us of our schoolboy days, when, trusting to a quick apprehension and a good memory, *amo* and *tupto* were shirked for cricket and football, bringing again and again upon us the denunciation of our masters, one of whom was constantly reminding us that it was seldom the clever child of the family turned out to be the best citizen, but the one who attended regularly and consistently to his work. The plodding boy, not the youthful prodigy, was with him the favourite. Edison and his colleagues—for such they are—have steadily and determinedly faced their difficulties, have

Digitized by Google

worked hard, and so far have been awarded a fair meed of success in popular estimation. Their motto is evidently *aut Cæsar aut nullus.*

MAGNETIC PROPERTIES OF MILD STEEL.

In a paper on "Certain Physical Tests and Properties of 'Mild Steel,'" read by Mr. Edward Richards at the annual meeting of the Iron and Steel Institute, held a few days ago, the author says:—"Before concluding this paper it may not be out of place to refer to some magnetic indications which may be observed in the process of making tensile tests on steel bars. A short bar of the mild steel used in these experiments, when placed in the line of the magnetic meridian, and held at the same time in the line of dip, is acted upon inductively by the earth's magnetism, and exhibits the attractions and repulsions of a true magnet, the north and south ends having north and south polarities respectively. Holding the bar in the same position, but reversing the ends, it is still magnetic, the ends pointing north and south having again north and south polarities. If one end of the bar be marked and the bar be reversed repeatedly, the polarity of the marked end will be found to be changed at each reversal. In this respect the metal behaves in exactly the same manner as the softest and purest quality of iron. Placed at right angles to the magnetic meridian, the polarity of the ends disappears, but the bar is found to be feebly magnetic, the lower side of the bar towards the north showing north polarity, and the upper side on the south the opposite polarity.

"It happens that at the Barrow Hematite Steel Company's Works the Kirkcaldy testing machine is placed north and south, and as the machine occupies a space more than a dozen yards in length, the different parts of the machine behave generally as a magnet. Upon testing a cylindrical bar of mild steel up to the point of rupture in this machine, the induced magnetism of mild steel becomes somewhat intensified with the rearrangement of the molecules under strain, and with the increase of elasticity; moreover, the magnetism becomes fixed. When the specimen is removed from the machine, either as a whole or in two broken pieces, it is permanently magnetic; the end which was towards the north having north magnetism, that is to say, it will attract the south end of a magnetic needle, and will repel the north end, no matter in what position the bar may be placed. With the aid of a small magnetic compass it is, consequently, easy upon trial to determine which end of a specimen was placed towards the north during tension. This behaviour is, of course, easily understood, but the author is not aware that it is generally known to be a constant occurrence in the process of testing steel bars or plate specimens.

"The position taken up by a small magnetic needle when placed in different positions near to a cylindrical specimen of mild steel undergoing test changes a little as the extension proceeds, and when the bar is broken the ends of the needle move through a very large angle, in some instances through a semicircle, taking up the opposite direction to that which they occupied before rupture took place. Placed east and west, the magnetism is not developed to any extent during tension, providing the surrounding parts of the machine have no magnetism. This was proved, at the suggestion of Mr. J. T. Smith, manager of the works, by testing a bar of steel in a small Whitworth testing machine placed at right angles to the magnetic meridian. Steel under compression also becomes permanently magnetic, the polarity of the bar being determined by the polarity of the magnetic field in which the specimen is placed during compression."

An Electric Tramway.—The Portrush and Bushnels Electric Tramway, near Belfast, the first that has been constructed in the United Kingdom, will be opened in the first week in August. The ceremony will probably be performed by the Lord-Lieutenant.

ELECTRICAL ACCUMULATORS OR SECONDARY BATTERIES.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

No. I.

A battery is an arrangement for setting electricity in motion, *i.e.*, for producing an electric current by means of chemical action. It generally, or always, consists of a liquid able to conduct electricity and of two solid conductors immersed in it, on which it is able to act chemically. If the two conductors differ in the smallest degree in respect of their chemical affinity for some active constituent of the liquid in which they are immersed, then, as soon as they are joined by a wire, a current is always found to flow—strong or weak, according to the degree of the difference between the surfaces of the two conductors, and also according to the dimensions and nature of the connecting wire and of the conducting liquid.

The distinction between a primary and a secondary battery is in no sense an important one when we are considering either as the producer of a current; and we may have in our minds an old Volta cell, or a Smee, Grove, or Daniell, just as satisfactorily as a Planté or a Faure, while we consider the ensuing few theoretical remarks.

I shall use the term "radicle" in preference to "element," as being more general. Radicles may be elementary, but they may also be compound. The atom of hydrogen, of oxygen, or of lead, is a radicle, but so is the group $S\,O_4$ or $N\,O_3$. A radicle is any group of atoms that can combine, or be removed from combination, with another group. Chemists have long been accustomed to divide radicles into electro-positive and electro-negative, or "basylous" and "chlorous," though they have been slow to recognise the full physical meaning of this distinction. They have also classified them into monad, diad, triad, radicles, and the like; and, without entering into the disputed question of whether atomicities are fixed or variable, it is absolutely certain that in a definite compound, and when released from definite compounds, certain radicles are monad, diad, or triad, as the case may be.

It is, moreover, known that radicles can exist temporarily in the free state, when they are said to be dissociated; and that many liquids—not to speak of gases—contain a number of such dissociated molecules, the number depending on the temperature as well as on the nature of the liquid, and being on the average pretty constant—that is, they are equally distributed through the whole liquid, and if some are by any means removed more will at once be formed to keep up the average. Not that any one radicle need remain long dissociated—there is, no doubt, a continual interchange—but the average number dissociated is definite under definite physical conditions.

Now there is a large class of liquids whose dissociated radicles are all charged with electricity—half of them with positive, and these are they which chemists call electro-positive or basylous radicles—half of them with negative, called therefore electro-negative or chlorous. Moreover, it was shown by Faraday that the charge possessed by every monad radicle, of what kind soever, is precisely the same in quantity, though it may differ in sign; and that diads have twice, triads thrice, this atomic charge, and so on. The existence of these charges is certain from the facts of electro-chemistry, and the electrical charge appears to be the essential condition for even the momentary existence of a free radicle. It further appears that when two opposite radicles combine their charges are either lost or are masked by proximity; and that before two radicles of the same kind can unite into a molecule their charges must be given up to some third body. A liquid which possesses such dissociated and oppositely charged radicles, sauntering about in it, is *ipso facto* susceptible of being decomposed by electrical means, and is called an electrolyte. Liquids which have no such charged and dissociated molecules are not electrolytes, and will not conduct electricity. Electrolytes conduct electricity by a bodily transfer in opposite directions of the oppositely charged radicles; they conduc

* We reprint these excellent articles from the *Engineer.*

Digitized by Google

it, in fact, as a convection current, or rather perhaps of two equal opposite convection currents, one of the positive radicles the other of the negative. The resistance of the liquid depends upon the slow shearing asunder of these two sets of radicles by a process closely analogous to diffusion, for it is possibly only assisted or directed by electricity in the immediate—molecular—vicinity of the electrodes.

What are these electrodes? They are conductors introduced into the liquid, with the property of exerting upon the charged radicles in their immediate neighbourhood unequal, or else opposite, forces. Thus, suppose they are two plates of platinum connected with a battery, so that one plate is always +, the other always −; and suppose for simplicity that the dissociated radicles are hydrogen—electro-positive, and oxygen—electro-negative, respectively. Oxygen atoms close to the positive electrode are attracted by it; they deliver up their charges to it, and uniting into molecules, rise as gas. Their places are taken by others from the slightly more remote region, and so on, a virtual procession of oxygen atoms continually taking place towards the positive plate, each carrying its charge with it. The same thing happens on the hydrogen side, only that twice as many hydrogen atoms take part in the action, the charge of each being half that of an oxygen atom.

This, then, appears to be the state of things in ordinary electro-chemical decomposition; only the radicles liberated on the surface of the electrode will combine with it, if in any way possible, instead of merely combining with each other and becoming free. Thus the hydrogen alloys itself as well as it can with the platinum; and the oxygen, if it finds any copper or other less noble metal on the surface of the electrode, will readily combine with it; the ordinary chemical affinities being enhanced by the electrical attractions.

But now, instead of two oppositely charged plates of the same material, let us immerse in the liquid a plate of zinc and a plate of copper, or any two metals which have a different affinity for oxygen. The oxygen atoms are now attracted to the zinc just as they were to the positive plate, but apparently by a chemical, not an electrical, force. It may be possible ultimately to reduce chemical forces to electrical ones, or *vice versâ*; but at present it seems necessary to draw a distinction between them. This attraction for the oxygen is, as before, only to be supposed to be effective within far less than a microscopic distance of the plate. The replenishment of the oxygen into this region is wholly carried on by diffusion and fresh dissociation. The copper on the other side pulls the oxygen too, but less powerfully. Nothing more than slight motion and very slow combination, however, is found to go on so long as the two plates are kept separate, provided both are pure and homogeneous; but the tending of the negatively charged oxygen towards the zinc makes it transfer negative electricity to the copper as soon as they are connected by a wire.

The copper so connected, being now negatively charged, actually repels the oxygen atoms, and is protected from their attack, while it attracts the hydrogen. We now therefore have the continuous opposite processions again, the oxygen atoms combining with the zinc, and neutralising by their charges positive electricity at its surface, in other words, partially giving up negative electricity to it; the hydrogen atoms going to the copper, hydrogenising it to some extent, but soon giving up their positive charges to it, uniting with each other and escaping from the liquid. A constant current must therefore be flowing along the connecting wire, of negative electricity from the zinc to the copper, of positive from the copper to the zinc.

Next, suppose two plates of the same metal, say both platinum or both lead, not connected with any battery, but with their surfaces in different chemical conditions—say one coated with hydrogen, the other with oxygen. Plainly the same kind of action can go on. The oxygenised plate will be attracting the hydrogen like the copper, or like the negatively charged plate connected with the pole of a battery; the hydrogenised plate will behave like the zinc or the positively charged plate. The positive current will flow along the connecting wire from the oxidised plate to the hydrogen-coated one.

We have thus a battery which will maintain a current so long as the plates continue coated or combined with the two gases; but the action of the current is obviously to destroy these gases and restore the plates to a condition of equality. A battery may be made, then, either of two different metals, one of which attracts oxygen more than the other—this case we will not now further consider—or else of two pieces of the same metal, one more oxidised than the other, or one more hydrogenised than the other; or, still better, one oxidised and the other hydrogenised. Take, for instance, two plates of lead and immerse them in dilute sulphuric acid; let one be bright and metallic, the other rusted over with a coat of oxide of lead. As soon as metallic communication is made between the two plates, a positive current of electricity continually flows along it from the oxidised plate to the other, the bright plate becoming gradually oxidised and the other becoming gradually reduced. If the plate has been oxidised by exposure to hot air, or by ordinary chemical means, such a battery would be called a primary one; if the coat of oxide has been produced by passing through the cell an electric current from some independent source, then the battery is called a secondary one.

I will next week consider more particularly the constitution and detailed behaviour of such secondary batteries.

Queen's College, Liverpool, May 16.

THE COST OF ELECTRIC LIGHTING BY INCANDESCENCE.

The following letter from Mr. W. Crookes, F.R.S., appeared in *The Times* for June 5:—

"Sir: For more than six months I have had the principal reception room in this house (7, Kensington Park-gardens, W.) almost exclusively lighted by incandescent electric lamps, the electricity being generated on the premises; and as so many different opinions have been given as to the expense of lighting by incandescent lamps, some saying that electricity is many times more expensive than gas, while others maintain that it is cheaper than gas, the results of my own private experience in electric lighting may not be without interest.

"The dynamo machine—a small Bürgen—is driven by a 3½ horse-power Otto gas-engine, which in favourable circumstances will develop 5 horse-power. Owing to the absolute necessity which exists in a private house in this neighbourhood that there should be no smell of unconsumed gases, and no noise of machinery either in the house or out in the street to annoy my neighbours, it became necessary to add silencing chambers to the air inlet and the exhaust pipe, and to carry the products of combustion high up on to the roof. The obstructions thus put in the way of the free working of the engine necessarily affect the horse-power, so that when a further deduction is made for the power absorbed in running the machinery when no electricity is being generated, I find I have not more than 2 horse-power available for the production of electricity. This is far from sufficient to drive the dynamo machine to its full power, therefore I lose greatly in efficiency both in the engine and the dynamo machine. However, I have only to deal with the facts as they show themselves in my experience. The total necessary expense of the installation has not exceeded £300, including wiring the house and making the lamps, although the actual expense to me has been much more, as I had to excavate and build underground rooms for the machinery. Where stables or out-buildings are available, or if a little noise is not prohibited, a less expense will give more available electricity, and where steam power can be used the cost will be diminished fourfold. The gas engine requires five minutes' attention every day to fill the oil cups and start it. Once started, it will go on without attention for six or eight hours. It is overhauled and cleaned once a week; an engineer does this on a Saturday afternoon, at a cost of 2s. 6d.

"The *maximum* electric current which I can get is 11·5

Digitized by Google

amperes through an external resistance of 12 ohms. The lamps fed by the current are distributed as follows:—In the library I have 11 20-candle lamps; in the dining room I have 10 20-candle lamps; in the drawing room I have a cluster of 21 4-candle lamps in an electrolier in the centre of the room and five 20-candle lamps. One or two lamps are in other parts of the house; the total number of lamps about the house being about 50. I cannot, however, have this number alight at once, as the machine as at present driven will not feed so many. It is, however, sufficient to light any two rooms perfectly, and the third partially.

"Switches are placed in cupboards in each room so as to turn any desired combination of lamps off and on. Main keys, cutting off the whole of the current at once, are placed in the engine room, and also in my laboratory at the place whence the main wires diverge to the different rooms.

"Owing to inexperience in adjusting the strength of the current to the kind of lamp used, and to the variety of systems, &c., I was then testing, the breakages during the first three months were somewhat numerous. For the last three months, however, since passing the experimental stage and settling down to a definite system, I have used lamps made by myself, and during this time only one lamp has gone.

"The gas burnt in the engine when the machine is feeding its *maximum* number of lamps (22 20-candle lamps) is about 550 cubic feet in five hours, costing, at 3s. 2d. per thousand, 1s. 9d. Assuming that the light is required on an average five hours a night all the year round, this would come to £2 9s. a month, or £31 17s. per annum.

"To obtain, not an equal amount of light, but a fairly good light from gas, to replace this amount of electric light, would take 30 gas burners, each burning 5ft. per hour, or 750 cubic feet in five hours, costing 2s. 4½d., or £3 6s. 6d. per month, or £43 4s. 6d. per annum.

"The expenses, therefore, per month stand as follow:—Electricity—Gas consumed in engine, £2 9s.; engineer once a week to clean and oil machinery, 10s.—£2 19s. Lighting by gas alone, £3 6s. 6d. Balance in favour of electricity per month, 7s. 6d.; or per annum, £4 17s. 6d.

"I have here charged only the current expenses. Strictly speaking, I ought to charge interest and wear and tear, but these are more than counter-balanced by the incidental advantages of electric lighting. With it the ceilings do not get blackened, the curtains are not soiled with soot and smoke, the decorative paint work is not destroyed or the gilding tarnished, the bindings of books are not rotted, the air of the room remains cool and fresh and is not vitiated by the hot fumes from burnt or semi-burnt gas, while fire risk is almost annihilated, as no lucifers are used, and the lamps are high up out of reach.

"In the above statement, I have compared electricity with gas as an illuminating agent. This is giving gas an unfair advantage. The 21 electric lamps in my drawing room do not replace gas jets, but wax candles, while the incandescent lamps in the dining room replace candles and oil lamps. The actual expense of these per night comes to three or four times the cost of electric illumination.

"Moreover, I am producing my electricity at an extravagantly dear rate. The dynamo machine works only about half power, and this greatly reduces its efficiency; while Messrs. Crossley tell me that a consumption of over 100ft. of gas per hour ought to give me double the power I get out of the engine; and doubtless it would do so were it not for the back pressure produced by the silencing boxes.

"When electricity is laid on to our houses as gas is all these extra expenses and difficulties will disappear; and if, as I hope I have shown, electricity, heavily handicapped as it is in a private house, compares favourably with gas even in the matter of cost, it will necessarily be far cheaper than gas when it is supplied wholesale from a central station."

ACCIDENT BY LIGHTNING.—At Peterborough on Saturday evening during a severe thunderstorm a woman, named Ann Smith, whilst walking through one of the streets of the town, was struck by lightning and instantly killed.

AUSTRALASIAN ELECTRIC LIGHT, POWER, AND STORAGE COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on the 5th inst., at the City Terminus Hotel, under the presidency of Mr. Randolph C. Want, when the following resolutions were submitted for confirmation:

1. That this Company so far modify the conditions contained in its memorandum of association as to consolidate the 5,000 founders' shares of £1 each into 1,000 founders' shares of £5 each.

2. That the 36th of the Articles of Association of the Company be amended by striking out the figures "5,000" on the 4th line of the 42nd page of the said articles, and by substituting the figures "1,000" in lieu thereof, and that the word "five" in the sixth line of the same page be struck out.

3. That the 108th of the Articles of Association of the Company be amended by striking out the figures "5,000" in the third line of the 47th page of the said articles, and by substituting the figures "1,000" in lieu thereof, and that the letters and figures "£1," in the same line of the said articles be struck out, and the letter and figure "£5" be substituted therefor.

The SECRETARY (Mr. J. H. Duncan) read the notice convening the meeting, and

The CHAIRMAN, in proposing the confirmation of the resolutions, stated that the alterations were merely owing to a clerical error. He might mention that they had sent out a very able and influential gentleman to the colonies to make arrangements there, and the news from the colonies showed that the Brush system was being adopted. The Post Office and the Arcade now employed it.

Lieut.-General H. MEADE HAMILTON, C.B., seconded the motion, which was carried, and the proceedings then terminated.

ABSTRACTS OF SPECIFICATIONS.

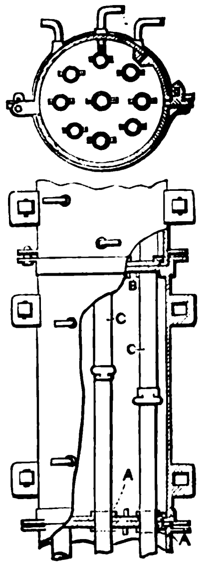
2704. IMPROVEMENTS CONNECTED WITH ELECTRIC APPLIANCES FOR MOVING AND OTHERWISE OPERATING UPON TRAMS, &c., *J Richardson, Lincoln.—20th June*, 1881.—(*Not proceeded with.*) 2*d.*

This invention consists in utilising an electric motor and secondary batteries to drive the tram car.

3790. IMPROVEMENTS IN AND RELATING TO THE COVERING, PROTECTION, AND INSULATION OF ELECTRICAL CONDUCTORS OR CABLES FOR TELEGRAPHIC, TELEPHONIC, AND OTHER PURPOSES, *W. R. Lake, London.—(A communication from S. D. Strohm, Philadelphia, U.S.)—31st August*, 1881. 6*d.*

The figure shows a section and a plan partly in section of the invention. The exterior casing is in two sections with external flanges, by which they are bolted together. The top section forms a movable cap, which facilitates inspection of the interior. Each cylinder has discs B, either forming a complete circle, or in sections as A A. These discs have annular grooves, into which the flanges of the sections of dies fit. They also

3790



have numerous openings for the passage of the tubes holding the wires. These tubes C C are formed in sections, and so constructed as to fit into one another; they are lined with insulating material and the wires laid inside. Modifications of this plan are also described by the inventor, whereby the joints are protected from moisture, &c., by india rubber rings, and fluid shellac is injected into the tubes and allowed to harden.

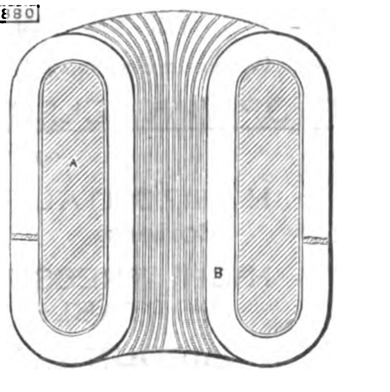
2770. IMPROVEMENTS IN ELECTRICAL RESISTING MEDIUMS, MORE PARTICULARLY ADAPTED FOR USE IN VACUUM AND OTHER ELECTRIC LAMPS AND TUBES, *R. H. Courtenay, London.—24th June*, 1881.—(*Not proceeded with.*) 2*d.*

This consists in preparing the carbon by first rubbing into the fibres of a skein of several threads of silk saccharine matter, such as date fruit, after which it is rubbed with a compound of plumbago, saccharine matter, and asbestos, to render it hard and smooth. The silk and compound are then gently heated. The inventor uses a compound of asbestos and fireclay as an insulator.

3880. IMPROVEMENTS IN THE MANUFACTURE OF REVOLVING ARMATURES AND OTHER PARTS OF ELECTRICAL APPARATUS AND IN MACHINERY THEREFOR, *W. R. Lake, London, 7th September*, 1881.—(*A communication from C. Dion, New York.*) 10*d.*

The figure shows the method of constructing the armature. The wire is ribbon shaped, and is placed in parallel coils around the walls of the armature in the following way—viz.: The outer portion of each coil is placed edgewise upon the outer surface of the core, the inner portion being arranged in the same way on the inner surface. The coils are insulated by being coated with gelatine treated with bichromate of potash, after which they are exposed to the light, whereby an insoluble film is produced. A is the core and B the wire. The core is made in two halves, upon which the wire, having been previously bent to the shape required to fit the coils by a special machine described in this specification and also

3880



the subject of this patent, is slipped, and the two halves are subsequently bolted together. The inventor claims that his system dispenses with commutators, as brushes can be applied direct to the conducting coils, one brush at the outside of the coils, and the other on a collector fitted on the axle of the armature. The coils also offer a small resistance as they have a large surface, and the risks of heating are reduced owing to the large cooling surface.

4069. IMPROVEMENTS IN AND RELATING TO INDICATING APPARATUS OR SIGNALS FOR RAILWAY SWITCHES OR POINTS, *W. P. Thompson, Liverpool and London.—21st September*, 1881.—(*A communication from W. W. Garz, Boston, U.S.*) 6*d.*

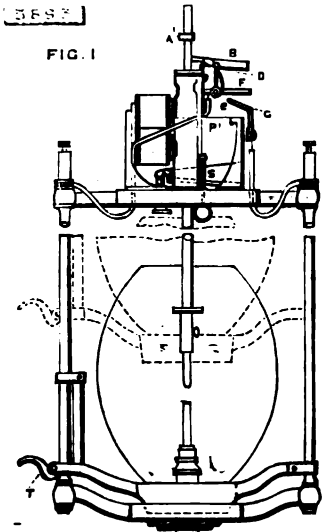
The object of this invention is to give advancing trains notice of the position of points whilst the trains are still distant from them, and is carried out as follows:—A switch, a magneto-electric generator, and a signal are so combined that the movement of the switch will cause the generator to actuate the signal.

3893. IMPROVEMENTS IN ELECTRIC LIGHTING APPARATUS, *W. R. Lake, London.—8th September*, 1881.—(*A communication from W. S. Hill, Boston, U.S.*) 8*d.*

This invention relates to improvements whereby a lamp may be automatically extinguished when the carbons are burnt low enough without affecting the other lamps in circuit; also to a means

3893

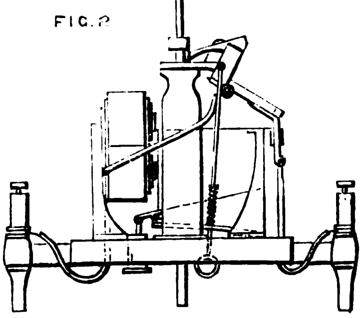
FIG. I



for lifting the glass globe, so that the carbons may be replenished from beneath without removing the globe. The figure shows the improvements as adapted to a Weston lamp, though they are applicable to other kinds of lamps. Supposing the arc to be formed the collar A^1, Fig. 1, is placed at such a point that when the carbons have burned as low as desired it will strike and depress inner end of lever B, causing it to release plate D, when the action of spring S moves the switch bar F to position shown in Fig. 2, or into closed contact with plate G, thereby offering a more direct passage for the current and diverting it from the regulating mechanism and carbons. The lamp having been supplied with new carbon; it can be put in action by drawing down rod P^1. To

3893

FIG. 2

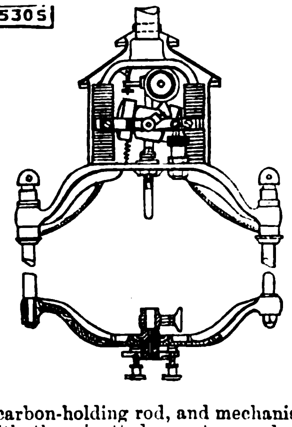


replenish the carbons the globe is raised by sliding its holder up the side rods, the cam lever T by bearing against the left hand rod, holding it securely where desired. Another part of the patent refers to a means for automatically lighting the second of a double set of carbons when the first are consumed.

255,305. ELECTRIC LAMP. *Hiram S. Maxim, Brooklyn, assignor to the United States Electric Lighting Company, New York, N.Y.—Filed August 4th*, 1881.

Claim.—In an electric lamp, a frame of magnetic metal supporting the feed-regulating mechanism, the sides of said frame being provided with pole pieces and wound with an insulated conductor forming part of the lamp circuit, substantially in the manner set forth, to form the feed-regulating magnets. The combination, in an electric lamp, of parallel cores, having consequent poles and coils included in the main or arc circuit, armature, pivotted between the said poles and having coils forming part of a shunt about

255305



the lamp carbon-holding rod, and mechanism connected with the pivotted armature and adapted to control the descent of the carbon holder, as set forth. The combination of pivotted armature, link, and frame, having shafts carrying friction wheels journalled therein, which are adapted to engage with the carbon holder, one of said shafts being provided with a friction disc whose rotation is controlled by a detent carried by the armature, substantially as set forth. The combination, in an electric lamp, with a carbon-holding rod, of a cut out or switch consisting of a pivotted contact lever and insulated terminals, and a spiral spring connected to the lever at a point directly above the fulcrum, as and for the purposes set forth.

4421. APPARATUS FOR USE UPON TELEPHONE LINES, *G. Pitt, Sutton.—11th October*, 1881.—(*A communication from C. E. Buell.*) 10*d.*

The design of the apparatus is to signal to one of several stations upon the same telephone line without producing a signal at the others. The invention also relates to the arrangement of lines, and the apparatus at the central station. The details are exceedingly numerous, and relate to no less than twenty-seven claims.

MARSHALL, SONS, & CO., LIMITED,

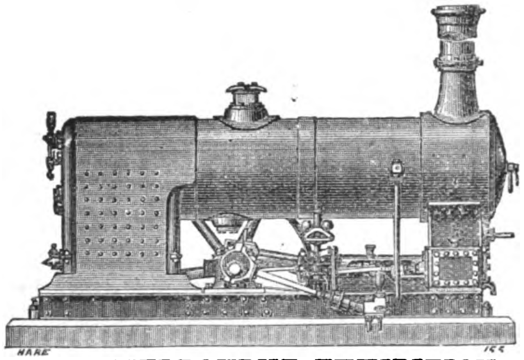
Britannia Iron Works, GAINSBOROUGH, & 3, King Street, Cheapside, LONDON, E.C.

MANUFACTURERS OF

STEAM ENGINES,

Fitted with Patent Automatic Expansion Valve Gear, and

SPECIALLY DESIGNED FOR DRIVING ELECTRIC LIGHT MACHINERY.



OF THE FOLLOWING TYPES:—

HORIZONTAL FIXED ENGINES, with separate Boilers,

HIGH PRESSURE PORTABLE and SEMI-PORTABLE ENGINES,

COMPOUND HIGH and LOW PRESSURE PORTABLE and STATIONARY ENGINES,

As used for driving a large number of the most important Installations in London and the Provinces.

MELBOURNE EXHIBITION, 1881.---Highest Award for all Exhibits. FIVE GOLD MEDALS.
SYDNEY EXHIBITION, 1880.---Two Special First and Four First Prizes.
PARIS EXHIBITION, 1878.---TWO GOLD MEDALS, and other Prizes.

Catalogues in English, French, German, Spanish, or Russian, free on application.

THE EXCHANGE TELEGRAPH COMPANY, LIMITED.

Head Offices--17 & 18, Cornhill, E.C.; Stock Exchange, E.C.; 27, Regent Street, W.

Incorporated the 28th March, 1872, under the Companies Acts of 1862 and 1867, and by Special License from H.M. Postmaster-General.

This Company will undertake to supply recording instruments, telegraphically connected with the Stock Exchange, by the aid of which Subscribers, at their respective offices, may be kept continuously advised throughout the day of the constantly occurring market fluctuations in stocks and shares.

Instruments are placed in the offices of Subscribers and kept in order by the Company, free of every expense but that of rent, and inspectors visit them daily to supply ink and paper.

Terms: £50 per annum, payable quarterly in advance.

Applications for instruments to be made to the Secretary at the above address.

Not having any springs or clockwork to wind up or to depend on, these instruments are acknowledged by those familiar with the system of telegraphy to be the only instruments yet invented that are capable of doing the work required of them continuously for a lengthened period, as evidenced by the fact that the Gold and Stock Company of New York, having the monopoly of this kind of business in the States, and which owns all the patents of the day of any value, has, after due trial, discarded all others.

The Company is prepared to treat with provincial Companies requiring instruments for the delivery of news for either single or double wire systems under the Company's patents, whereby from central stations identical information can be simultaneously delivered to any number of recipients by automatic, self-adjusting, printing instruments requiring no local batteries, no winding up, and no knowledge of telegraphy on the part of the receiver, the printing being in bold roman type, and the propulsion of the paper being effected by the electricity supplied from the Central Office.

The instruments supplied by the Company can be had to work either on single or double wires, and to print either on a slip or tape of paper, as has hitherto been the custom, or on a broad band of paper in column form.

LIFE ASSOCIATION of SCOTLAND.
Founded 1838.
HEALTHY PERSONS OF ALL AGES will find in the BONUS SYSTEMS of the LIFE ASSOCIATION of SCOTLAND advantages far exceeding those which can be obtained under any of the ordinary systems.

Claims and Bonuses paid	£4,028,000
Annual Revenue	436,000

Immediate Entrants in Class A will secure ONE YEAR'S BONUS MORE THAN LATER ASSURERS in that class.
LONDON—5, Lombard-street, and 48, Pall Mall.
EDINBURGH—82, Princes-street.

CITY and GUILDS of LONDON TECHNICAL COLLEGE, COWPER-STREET, FINSBURY, E.C.—WANTED, an ASSISTANT in the PHYSICAL LABORATORY. One with a practical knowledge of dynamo-machines preferred. Apply in writing, sending testimonials, salary expected, &c., to Professor AYRTON.

WANTED, a PRIVATE SECRETARY.—Business habits, a good knowledge of shorthand, and some acquaintance with physics essential. Apply in writing, sending testimonials, salary expected, &c., to Professor AYRTON, 68, Sloane-street, S.W.

TO ELECTRIC LIGHTING COMPANIES or CAPITALISTS.
WANTED, ASSISTANCE to carry out final experiments upon an entirely new form of Secondary Battery—not copying in any way any patent now before the public. The expense would not be great to a Company, owing to the conditions which would be made. It is believed from present experience that it would be the best accumulator yet produced (not patented). Any Company or Capitalist rendering assistance would have right to the same on very reasonable terms.
Address, ACCUMULATOR, office of this paper.

JUNIOR DRAUGHTSMAN REQUIRED for Electric Light Machinery. One accustomed to Locomotive or Machine tools preferred. Apply, between 10 and 12 a.m. only, R. E. CROMPTON, 4, Mansion House-buildings, Queen Victoria-street.

A PRACTICAL ENGINEER and ELECTRICIAN (Assoc.Mem.I.C.E.) wishes an ENGAGEMENT. Accustomed to both Lighting and Manufacture. Highest references and testimonials.—Address, "D. E. R.," ELECTRICIAN Office.

ELECTRICAL BUSINESS for SALE, with STOCK and PLANT and new ELECTRIC LIGHT APPARATUS. Apply by letter first, "B. J.," 518, Oxford-street.

SMALL GRAMME MACHINE, A type. Almost new. 6,000 candles. To be SOLD. Apply, SYDNEY B. HODGE and SONS, Field-gate-street, E.

ELECTRICITY.—WANTED, by a Mechanical Engineer, SITUATION with Electric Light Company as UNDER MANAGER or DRAUGHTSMAN. No objection to travel.—G. H., 23, Temple-row, Birmingham.

A YOUNG MAN with capital is desirous of meeting with an opening leading eventually to a PARTNERSHIP in a well-established firm of Telegraph or Electric Engineers.—Apply, by letter only, to H., care of Messrs. Ingle, Cooper, and Holmes, City Bank Chambers, Threadneedle-street, E.C.

INSULATED ELECTRICAL WIRE, Silk, Cotton, or India-rubber covered. Conductivity guaranteed. German Silver Wires for Resistance. Braided Handle Cord, Silk Cord for Electric Bells, &c.—WILLIAM RICKARD, Derby. London Agent (stock kept), EDWIN HOLLOWAY, 2, Gutter-lane, E.C.

SLIP

DIVIDEND.—The directors of the Eastern Extension, Australasia, and China Telegraph Company have declared an interim dividend for the quarter ended the 31st of March last of 2s. 6d. per share, or at the rate of 5 per cent. per annum, payable on the 15th prox.

THE RIOT AT ALEXANDRIA.—It is stated that the two Manchester men, Mr. Robert J. Dobson and Mr. Reginald J. Richardson, who were killed in the riots last Sunday, met their death while attempting to save some of the staff of the Eastern Telegraph Company who were in peril.

ELECTRIC LIGHT FOR CANALS.—It is stated that electric lights are being erected along a portion of the Surrey Canal, and it is probable that the whole length will eventually be lighted by the same means. This canal runs through the South East District of London to the Docks.

ELECTRIC LIGHT AT HARWICH.—It is stated that the South Eastern "Brush" Electric Light and Power Company have received orders from the Great Eastern Railway Company for lighting their works at Parkeston Bay, near Harwich, which will be carried out during the present month.

THE TELEPHONE IN CEYLON.—The latest news from Ceylon states that the electrician of the Oriental Telephone Company is in Colombo arranging for the erection of wires, and an experimental exhibition is soon to take place. The *Ceylon Observer* believes the system will become very widely adopted.

WHEATSTONE'S AUTOMATIC SYSTEM IN AMERICA.—The *Operator* says that the Western Union Telegraph Company is preparing to use the Wheatstone automatic system, so extensively employed in Europe, especially for sending Press reports. A number of operators are practising punching and slip reading.

ROYAL HORTICULTURAL SOCIETY.—This society gave its annual *fête* in the Gardens at South Kensington on Tuesday evening. The corridors round the Gardens were lit by Messrs. Siemens' electric lamps; the Gülcher Electric Light Company lighted up the great conservatory with their lamps; whilst the Brush Company lighted the ante-garden.

CENTRAL AND SOUTH AMERICAN CABLE.—The India Rubber, Gutta Percha, and Telegraph Works Company have received a telegram, announcing that the ss. "G. E. Wood" has completed the laying of her cable, and is now on her way home, and that the ss. "International" has landed the shore end at Galveston. All well on board.

TELEGRAPH INSTRUMENTS, &c., WANTED.—The Highland Railway Company are inviting tenders for the usual annual supply of wire, telegraph instruments and fittings, &c. Forms of tender may be obtained of Mr. J. G. Bulmer, storekeeper, Inverness. Tenders are to be sent to Mr. A. Dougall, secretary, at the company's office, in Inverness, addressed to the Directors, by the 24th instant.

EXHIBITION AT FALMOUTH.—This being the jubilee year of the Royal Cornwall Polytechnic Society, it has been resolved to hold an exhibition at Falmouth in commemoration of the event. The Exhibition will be held in the Polytechnic Hall and the Volunteer Drill Hall, and is to be opened on the 5th September. Electricity and electric lighting will form a prominent feature of the Exhibition.

A NEW USE FOR ELECTRIC LIGHTS.—A Cleveland (Ohio) paper of recent date says:—"On Thursday evening at 10 o'clock a flock of wild ducks in their flight over this city were attracted by the brilliant glare of the electric light on the Bank-street mast, and several of the birds flew directly against the lamps, shattering three of the glass globes and bringing down three good fat ducks, which were triumphantly carried away by passers-by."

ELECTRIC LIGHTING FOR THE NAVY.—A special committee, consisting of Captain Eardley Wilmot and Mr. J. Farquharson, of the Admiralty; Captain Gordon, of the "Vernon;" and Mr. Owen and Mr. Newman, Chief Constructor and Chief Engineer of the Dockyard, is conducting an exhaustive inquiry at Portsmouth into the merits of various systems for the electric lighting of ships of war. The inquiry is confined to the use of incandescent lamps.

SEVERE THUNDERSTORM.—A severe thunderstorm visited King's Lynn, in Norfolk, on the 13th inst. It is reported that at Massingham, twelve miles distant, the Abbey Farmhouse was struck by lightning and entirely destroyed. At Terrington St. John, seven miles west of King's Lynn, twelve houses were injured. Thirteen horses and 36 sheep are stated to have been killed at Watlington. No loss of human life appears to have taken place, however.

TELEGRAPH STORES WANTED.—Tenders are invited for the supply of 336 tons of galvanised annealed iron telegraph wire, 35,000 porcelain insulators, 35,000 galvanised iron insulator brackets, 80,000 galvanised square-headed iron wood screws. Particulars may be obtained at the Ministry of Posts and Telegraphs (Direction du Materiel et de la Construction), Rue de Grenelle Saint Germain 103, Paris, where tenders will be received up to the 20th instant.

THE TELEPHONE IN SHEFFIELD.—The Sheffield correspondent of the *Engineer* says:—"The Sheffield Telephone Exchange makes very rapid progress, thanks in a large measure to the attention given to it by the managers, Messrs. Tasker, Sons, and Co., Angel-street. On the 24th of May, I am informed, there were 240 messages sent in one hour, between 10 and 11 o'clock. The day's return was 1,294. The following day (Thursday) there were 1,290 messages. These are the two highest days on record."

ANGLO-AUSTRIAN BRUSH ELECTRICAL COMPANY.—The prospectus of this Company has just been issued. It has a capital of £500,000, of which £300,000 will first be issued in £5 shares. The Company has been formed to work the patents of Mr. Brush and Mr. Lane-Fox in Austria and Hungary. Copies of the prospectus, &c., can be seen at the offices of the solicitors, Messrs. Hollams, Son, and Coward, Mincing-lane, E.C. The secretary, *pro tem.*, is Mr. Miall Fraser, 4, Copthall-buildings, Bank, E.C., and Mr. C. H. Benton will act as electrician.

LIST OF CABLES INTERRUPTED.—The following is a list of the telegraph cables at present interrupted:—St. Thomas and St. Kitts, St. Vincent and Grenada, Guadeloupe and Dominica, and the Paris and New York Telegraph Company's cable.—South America: The cable between Rio Grande do Sul and Monte Video is interrupted.—West Indies: The cables between St. Thomas and St. Kitts, and between St. Vincent aud Grenada are interrupted; and there is, therefore, no telegraphic communication with the Island of St. Kitts, Antigua, Guadeloupe, Dominica, Martinique, S. Lucia, St. Vincent, and Barbadoes.

NEW COMPANY.—The prospectus of Edison's Indian and Colonial Electric Company (Limited) has been issued. The company has been formed to work Edison's inventions in India, Ceylon, Australasia, and South Africa, it also has the sole right to use in those countries any improvements which

Digitized by Google

Edison may introduce in his apparatus during the next five years. The capital is £250,000, in 40,000 "A" shares and 10,000 "B" shares of £5 each; 5,000 "A" shares; and all the "B" shares are taken as part of the purchase money. The "B" shares will receive no dividend until the "A" shares have received a cumulative dividend of 6 per cent.; 35,000 "A" shares are offered to the public.

Long Distance Telephoning.—Recent experiments have been made with M. van Rysselberghe's system of telephony, during which a message was sent by telephone over a long distance at the same time that a telegraphic message was traversing the same wire. The first experiment was made on an ordinary telegraph wire 353 kilometres long, between the railway station at Paris and that at Nancy. The second was made between Paris and Brussels, over a wire 344 kilometres long. It is stated that the telephonic message was distinctly heard, whilst the telegraphic message was distinctly rendered by the Morse instruments employed, although both were sent at the same time and along the same wire. M. van Rysselberghe is well known as the head of the Meteorological Observatory at Brussels, and an ingenious electrician.

The Disintegration of Electrodes.—According to an article by Messrs. Reitlinger and Wächter in the *Ann. Phys. Chem.*, the discharge of positive electricity is the sole cause of the electrical disintegration which occurs at the surfaces of flat, spherical, or pointed metallic electrodes. The authors have ascertained that whenever negative electricity traverses a resinous surface, it always leaves traces of a circular spreading, whilst positive electricity can, according to circumstances, occur either in radial lines, or in circular discs or rings. An inversion of Lichtenberg's figures, by means of which negative electricity would give a radiating figure, is found to be impossible down to the smallest lines or rays. The positive Lichtenberg radiating figures are caused by minute particles detached from the electrode, whilst the positive as well as the negative disciform figures are produced by gaseous discharges.

Self-Generating Electric Light and Power Company.— In explanation of the title "Self-Generating," assumed by this recently floated company, the secretary writes, "that the title 'Self-Generating,' in the absence of any other sufficiently concise term, was selected to distinguish this company as independent of any external motive-power and machinery in the production of its light, each separate establishment having, therefore, self-generating apparatus for its light. The patentee claims to effect this result by a method of constructing and charging batteries for the production of electricity sufficiently cheap, and capable of lasting sufficiently long, to bring this method within the region of practical operation." We shall not endeavour to give any opinion upon the manner in which this company was brought before the public; but this we do know, that there is no battery in existence at present capable of competing economically with dynamo machines to supply light and power.

Effects of Currents on Magnetised Electrolytes. —In a recent number of the *Proceedings of the Royal Society* Mr. G. Gore treats of certain electro-magnetic rotations produced in liquids by means of axial electric currents, either in the interior of vertical magnets, electro or permanent, or near their poles, which differ from rotations previously described by the absence of radial currents. According to the author a column of an electrolyte enclosed in an electro magnetic helix is twisted in a similar manner to an iron wire or rod placed under similar conditions. The rotations produced in liquids are strongest at the poles and a little distance beyond them, and *nil* at the centre. The rotations within the tube and to a short distance beyond are opposite to those produced by a voltaic solenoid; a magnet tube has then three points of rotation with an axial current, one at its centre and one near each end, whilst a solenoid has only the former. These phenomena are more definite and powerful with a tubular electro-magnet than with a voltaic current alone.

Electric Light on the Embankment.—The following is from the report of the Metropolitan Board of Works for 1881, which has just been issued:—"The Victoria Embankment and Waterloo Bridge continue to be lighted by electricity, according to the method devised by M. Jablochkoff. There are forty lights on the Embankment wall and ten on Waterloo Bridge. The lighting is undertaken by the same French company as originally introduced the system into London. When the company first began to charge for the light at so much an hour for each lamp the rate agreed upon was 5d. an hour. At the end of three months the price was reduced to 3d. on condition that this should continue for six months, and, at the end of that time, the company made a further reduction in the price, agreeing to continue the light for one year, at the rate of 2½d. per light per hour. This last agreement was made in April, 1880, and continued until June, 1881, when a fresh agreement was made with the company to continue the lighting for a term of three years from that date, at the rate of 1½d. per light per hour.

The Electric Light Bill.—The Select Committee on this Bill met on Monday for the further consideration of the clauses of this Bill. The committee consulted in private to consider the proposal made by Mr. Wright, Q.C., on behalf of the gas corporations, and subsequently announced their decision. They decided to insert a clause empowering any local authority, company, or person who had obtained a license, to contract with any company or person for the execution and maintenance of any works required for the supply of electricity, but providing that no local authority, company, or person should by any contract transfer to any other body, or divest themselves of any powers given to them, or legal liabilities placed upon them by the Act. The remaining clauses of the Bill having been passed, the committee rose. It was expected that they would bring up their report on Thursday last. The *Standard* hears that the Bill is threatened with considerable opposition. The electric companies hold that the monopoly of fifteen years which the Bill proposes to give is too short, and intend to make an effort to get it extended to twenty-one or twenty-five years.

The Edison Lighting Station in New York.—The latest account of the progress that has been made in laying mains, &c., for the New York lighting station of the Edison Company states that, prior to the 1st April, a little over 55,000 feet of street underground conductors had been laid, including mains on the block fronts, street intersections, and feeders. The work of laying intersection safety catch boxes was begun experimentally in March, but only one box was actually laid in that month. The next month thirteen were put in. The total amount of mains laid during April was 12,500 feet, making about 67,700 feet of conductors already put in the ground. On the 1st May there yet remained to be laid about 14,300 feet, including not only street mains, but also connections at street intersections, feeders, and some extra mains specially required, also forty-seven street intersection safety catch boxes, and forty-eight bridge safety catch boxes. These boxes were described and illustrated in the last volume of *The Electrician*. Three out of the six large dynamos that

Digitized by Google

are eventually to be erected in the central station in Pearl-street are now being erected there. The others are ready and will follow as soon as the first three are in place.

ELECTRIC LIGHT FOR TORQUAY.—The question of the adoption of electric lighting came before the Torquay Local Board at their last meeting, when it was ultimately decided to let the matter remain for the present in abeyance, until the various systems had had a more extended trial. In the course of the discussion on the subject a Mr. Murray, member of the board, stated that when in London recently he "made inquiries into the matter, and was shown [we quote from a local contemporary] a report of the practical working of the electric light at one of the large railway stations for a period of nine months. An area was illuminated which would require 228 gas jets. Counting the gas at 3s. per 1,000 feet, there was a small balance against the working of the electric light of £7 and a few shillings on the nine months' working. With respect to the gas at Torquay, for which the town was paying 3s. 9d. per thousand feet, a saving under similar circumstances would be effected of something like £100 a year. It was most important that the town should acquire its own lighting. They saw the result of an opposite policy in the 7 and 10 per cent. which was now going into the pockets of the shareholders of the gas company, and which should have gone towards diminishing the rates, a course of action which he took to be one of the especial functions of such a body as that board."

COLONIAL EXHIBITION AT AMSTERDAM IN 1883.—The preparations are being actively pursued for an exhibition of a decidedly novel character to be held next year in the Dutch capital. The primary idea is, by showing the indigenous produce of the colonies of the various European states side by side with the articles most suitable for exportation, to favour and incite a judicious and more active interchange. In Group III., devoted to Europeans in their relations with the native inhabitants of the colonies, Class 18 relates to telegraphs, postal service, and telephones, with appliances, models, and drawings. In Group VII., machines, tools, and means of transport, Class 43 includes plant and apparatus connected with electricity, telegraphs, and telephones. Exhibitors are invited to send in reports, statistics, and treatises on all the subjects included in the programmes, and generally on all questions affecting exportation. The Exhibition is under the patronage of the King of Holland and the Dutch Government, and under the honorary presidency of the Colonial Minister. The president is M. J. Léonard Wolterbeek; the secretary, M. Th. Stuart; and the general commissioner, M. E. Agostini; while the president of the Executive Council is M. D. Cordes, with M. J. Kappeyne Van de Coppello as secretary. The Exhibition is to open on the 1st May next, and to remain open at least five months.

THE GAS INSTITUTE.—The nineteenth annual meeting of the Gas Institute was held on Tuesday at the Institution of Civil Engineers. Mr. G. W. Stevenson, the president, in his inaugural address, observed that they honestly believed that they had the best artificial light for general purposes, and they would, therefore, be false to themselves if they did not take infinite pains to demonstrate to others the advantages of this light over that of tallow, oil, petroleum, or electricity. The electric light had come on them not as a novelty, but as a somewhat more practical competitor, and in proportion as its promoters were successful in improving and cheapening it, it would become formidable as a competitor with gas for the lighting of streets and dwellings. At present, however, they had nothing to fear from it, but its very presence among them ought to stir them up to maintain the supremacy they held. He said the proposals of the Electric Lighting Committee showed how the Board of Trade was gradually seeking to arrogate to itself the powers hitherto somewhat jealously guarded by Parliament. If these proposals were adopted, especially the granting of licenses permitting promoters to break up the streets to supply electricity in competition with gas, the *quasi* monopoly of gas companies would be placed on the same footing as the chances of an omnibus proprietor, who is liable at any moment to have his business interfered with by a tramway company.

TELEGRAPH CLERKS GRIEVANCES.—A letter appeared in *The Times* of June 15, in answer to Mr. Fawcett's letter to Mr. Macliver, which we gave extracts from in a recent issue. The writer, who signs himself "Metropolitan," says:—"Last year the telegraphists urged upon the Postmaster-General the desirability of abolishing classification, but most unfortunately without avail. It can now be seen how baneful are the results of a system which has received new life at the hands of the Postmaster-General. The old third-class maximum was £65 per annum, at which stage numbers of men stood still for years. That class was recently abolished, and the maximum of the lowest class was made £100 per annum. At the same time the next class was extended, and promotions to it were given to as many clerks as were necessary to fill up the new vacancies. In this way three clerks in the London districts were promoted from £65 to £110 per annum, but, at the same time, only a £5 increment was given to others who had been in the service equally long, and for whom there is now a weary five years of toil before they will reach the maximum of their present class, which is only £100 per annum. Now, had classification been abolished, instead of larger increments being given to some than were necessary to place them in their proper positions, we should have had the money which was voted by Parliament last year more justly distributed, and, without any additional cost to the country, we should have seen no such cases of inequality as a £45 increment being given to one clerk and only £5 to another with an equal claim."

TELEGRAPHS IN NEW SOUTH WALES.—The growth of the telegraph in this Australasian colony is well shown by the following extract from a statistical and descriptive account of the colony, published annually by Mr. Thomas Richards, government printer:—"Telegraphs have been rapidly extended in New South Wales. The first line was opened on 26th January, 1858. The following figures record the growth of the telegraph department during the ten years 1871 to 1880: 1871, miles of wire, 5,579, 1880, 13,188; 1871, stations, 89, 1880, 289; 1871, messages, 218,530, 1880, 1,319,537; 1871, cost of construction, £195,245, 1880, £462,226; 1871, revenue, £32,665, 1880, £84,110. The length of telegraph wire is much greater in New South Wales than in any of the other Australian colonies, and bears favourable comparison with the extent of lines in older countries. Up to the end of 1881, there were 13,688 miles of telegraphic wire laid, and 328 stations. The revenue was £100,000. Nearly all the recent improvements have been adopted by the department, and its show of scientific apparatus at the recent International Exhibitions was of a complete and interesting character. Telegraphic lines are not only to be found in all the centres of population, but they have been extended to the most remote districts, and the scale of charges has been greatly reduced, which has caused the expenditure to exceed the revenue of late years. For one shilling a message of ten words can be sent to any station in the colony, and for two shillings to any part of the Australian Continent. Thanks to the enterprise of South Australia

there is a line 1,800 miles long, from Adelaide to Port Darwin, which, connecting with the ocean cable, unites Australia with every part of the world."

On Rotary Polarisation by Chemical Substances under Magnetic Influence.—This was the title of a recent paper read before the Chemical Society by Mr. W. H. Perkin. The object of the author was to discover, if possible, whether any relationship existed between the chemical composition of substances and their power of rotating the plane of polarisation when under the influence of magnetism. The apparatus used was similar to that employed by Becquerel. The liquids being placed in the tubes closed at their ends with glass plates, the ends of the tubes were inserted a short distance into perforations in the armatures. Water and carbon disulphide were used as standards. The author's results, which were calculated for unit lengths of the fluids, agreed pretty closely with those of De La Rive and Becquerel, but seemed to bear no relationship to chemical composition. On consideration it seemed probable that unit lengths of vapours would give better results. It was soon apparent that the direct estimation would be attended with too many difficulties; the results of the observations obtained with unit lengths of fluids can, however, be referred to the lengths of columns of liquids which would be formed by the condensation of unit columns of their vapours, in other words to lengths related to each other in proportion to their molecular weight, making the necessary correction for difference of densities. This can be done by the simple equation $\frac{r \times m\,w}{d}$, r being the observed rotation, $m\,w$ the molecular weight, and d the density. Having made this calculation for the substance under examination and for the standard with which it is compared, the molecular co-efficient of magnetic rotation, or more briefly the molecular rotary power, can be obtained by dividing the former by the latter. The numbers thus calculated clearly indicate that the molecular magnetic rotary power follows the chemical composition.

Indian Telegraphs.—According to the annual report of the Indian Telegraph Department for 1880-81 some slight changes were introduced during the year, reducing the number of free messages, and relieving the department of the charge of the lines in Ceylon, which were re-transferred to the Ceylon Government. The lines in Afghanistan were dismantled, new lines were added to existing supports, and other similar changes of an unimportant nature took place. The total miles of lines were 19,679, and of wires 54,433, besides 1,655 miles of wire maintained by the department for the service of railway companies. Messages increased in number from 1,562,511 in 1879-80 to 1,656,230, of which 297,753 were foreign and the rest inland. The surplus of earnings over working expense was 13,19, 363 rs., the same as in the previous year, the working expenses being about 32 lacs, and the earnings 45 lacs. Although the number of messages has increased, the average time occupied in their transmission along the main routes has decreased. The average time taken to send messages from Calcutta to Bombay was one hour and six minutes, to Madras one hour and fourteen minutes, to Rangoon two hours and nine minutes. The following is an analysis of the complaints made during the year:—For non-delivery 140, for delay 56, for error 121, miscellaneous 5. This shows a slight improvement on the previous year. There were also 5,250 undelivered messages, mostly due to insufficient or incorrect addresses. The interruptions which occurred on different lines owing to heavy floods during the monsoon were neither numerous nor long, and the worst appears to have been one caused by landslips at Naini Tal, which lasted 328 hours. Among some of the principal extensions mentioned as having taken place is a second wire for forty miles added to the Moulmein-Amherst line, and carried on to Tavoy; a new three wire line, 136 miles in length, constructed along the Holkar Sindia-Neemuch State Railway, and a line, forty miles in length, from Dera Ismail Khan to Tonk. The report states that telephones were put up to connect several of the Government offices at Simla, and were also used during the siege of Candahar in August, 1880.

Electric Lighting in Hull.—The *Eastern Morning News* of recent date contains the following account of the progress made by Messrs. Siemens Brothers in the erection of their lights at Hull. It will be remembered that this firm lately contracted with the Corporation to erect and maintain their lights in portions of the Old Town and Town Hall for twelve months. It is hoped that the lighting may be begun early in July. Our contemporary says:—"The streets will be lighted by means of four large arc lamps, each of 3,000 candle-power, and 22 smaller arc lamps, of about 350 candle-power. The current for each of the large lamps will be generated by a separate machine, of the type known as the 'continuous current' machine. Each lamp will be placed in large alabaster globes, fitted with reflectors for diffusing and throwing down the rays of light, and suspended at a height of about 50ft., on the tubular standards erected at the bottom of Whitefriargate, the west end of Holy Trinity Church in the market-place, at the corner of Mytongate, and on the Victoria Pier. The 22 differential lamps will also be placed in alabaster globes, and at a height of 20ft. from the ground, on the posts now standing in the streets, and distributed as follows:—Lowgate, five; Market-place, three; Queen-street, three; Nelson-street, three; Victoria Pier, one; Silver-street, one; Whitefriargate, four; North and South Church-side, one each. These lamps will all be maintained by means of one machine of the 'alternating current' type, and arranged on two circuits of eleven lamps each. This machine is capable of maintaining 32 such lamps should extensions be found desirable. In the Town Hall five powerful arc lamps, of 1,000 candle-power each, maintained by one 'continuous current' machine, will be employed for lighting the entrance hall and the reception room; while in some of the smaller rooms and offices 50 incandescent lamps will be distributed. In the Council Chamber special arrangements will be made, by means of which it can be lighted at pleasure, either by means of one powerful arc light suspended in the centre of the room, or by 60 incandescent lamps attached to the existing gaseliers. The whole of the machines will be fixed in a shed in the yard of Messrs. King and Co., South Church-side, and driven by two 12 horse-power compound semi-portable engines. The current will be conveyed by means of copper conductors, carefully insulated with gutta percha, and laid in 6in. iron pipes, boxes being provided where necessary for connecting the mains with the various lamps. In order to make assurance doubly sure, and avoid any possible risk of fire, all the wires in the Town Hall will be covered with india rubber and tape, while each individual lamp will be provided with a safety-plug, so constructed as to fuse and immediately break the circuit should any undue heat occur. Every care and precaution has been taken to render this installation an unqualified success, and the experience of Messrs. Siemens, and the completeness of their system render failure almost an impossibility. The work in Hull is being done under the superintendence of Mr. W. W. Melhuish, engineer."

THE PHENOMENA OF THE ELECTRIC DISCHARGE WITH 14,400 CHLORIDE OF SILVER CELLS.*

BY WARREN DE LA RUE, ESQ., F.R.S., SEC.R.I., ETC.

(CONTINUED FROM PAGE 80.)

Between discs the law of the electric discharge is not the same as between points; its length does not increase nearly so rapidly, as will be seen by a reference to the diagram (Fig. 7), which represents the discharge between two points, a point and disc, between spherical surfaces, and between concentric cylinders. But the increment of potential necessary to produce a discharge for a given distance between discs, say a centimetre, becomes less as the distance between discs, and consequently the potential, are increased. Thus, the electrostatic force per centimetre with 1,000 volts and a striking distance of 0·0205 centimetre, is 163 electrostatic units, while it is only 113 units with 11,000 volts and a striking distance of 0·3245 centimetre.

We have found, moreover, that the discharge between discs in air, hydrogen, carbonic acid, and probably also in other

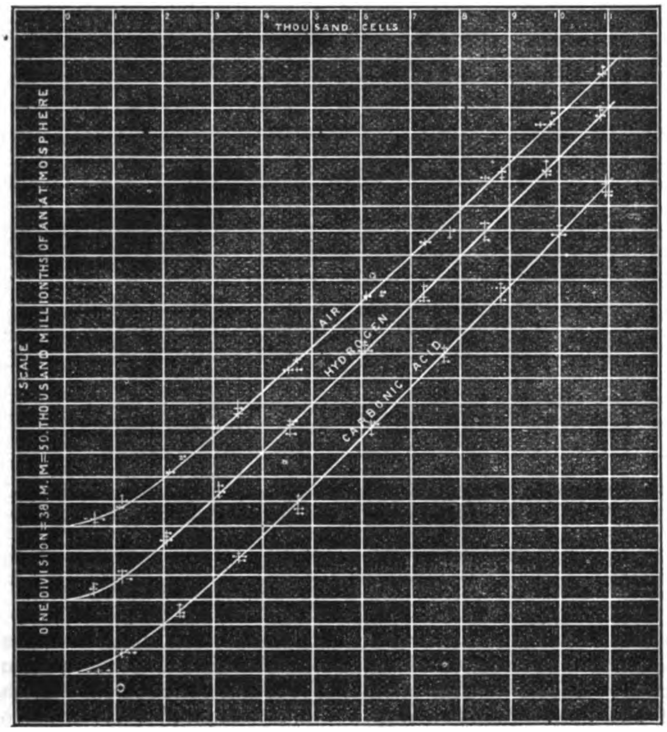

FIG. 8.

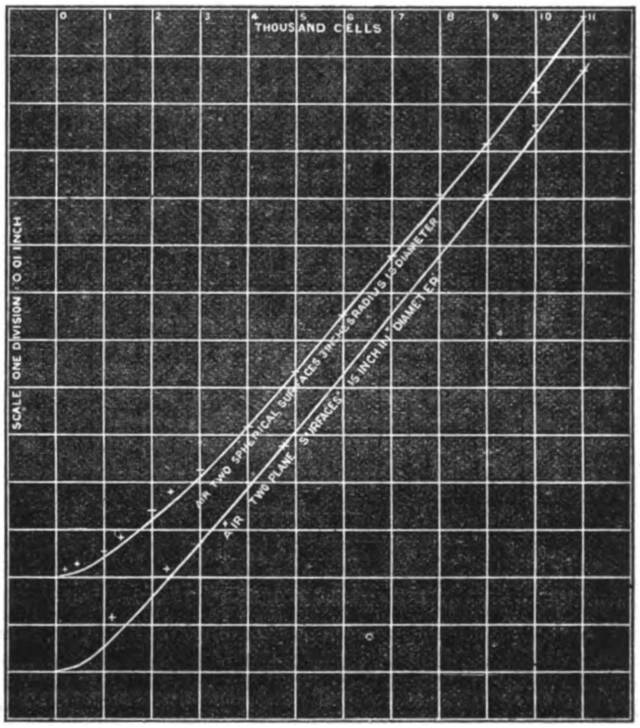

FIG. 9.

gases, may be represented by a hyperbolic curve, and this is the case whether we send the discharge through the gas at a constant pressure and increase the distances between the terminals and also the number of cells, or send the discharge at a constant distance and vary the pressure and number of cells; the obstacle in the way of a discharge being as the number of molecules between the terminals *up to a certain point*, as will be seen in the diagrams (Figs. 8 and 9), in which the cross marks represent the actual observations. For although the potential necessary to produce a discharge diminishes as the pressure decreases, yet this is true only up a certain limit; after this has been reached it rapidly increases, and ultimately the resistance becomes so great, as the exhaustion is carried further, that it is easier for a spark to pass between terminals placed at the same distance outside the tube in air at atmospheric pressure. The diagram, Fig. 10, in which the abscissæ are the cube roots of the pressures in millionths of an atmosphere, and the ordinates the number of cells necessary to produce a discharge in a hydrogen tube 30in. between the terminals, shows the results of experiment. The pressure of minimum resistance varies for different gases. We have determined it to be 0·642 mm. = 845 millionths of an atmosphere for hydrogen, at which pressure the potential necessary to produce a discharge through a tube with terminals 30in. apart was found to be only 430 cells. At a pressure of 0·0065 mm., 8·6 millionths, it requires as high a potential, 8,937 cells, as at a pressure of 21·7 mm., 28,553 millionths, to cause the discharge to take place. At 0·00137 mm., 1·8 millionth, 11,000 cells, will not pass. The greatest exhaust we have obtained in a hydrogen vacuum and an absorption by spongy palladium was 0·000055 mm., 0·07 millionth, which offered so great a resistance that a 1-inch spark from an induction coil could not traverse the tube. I will now exemplify what I have said by showing you a tube with an absorption chamber (Fig. 11). I expect that the vacuum will prove to be so good that the whole of the battery, 14,400 cells, will not cause a current to pass. You see there is no illumination of the tube; if I now heat the absorbing material so as to cause gas to enter the tube, then the discharge of a much smaller number of cells—namely, 3,600, illuminates the tube, and if I allow it to cool again the discharge ceases.

It has been suggested that there is a polarisation of the terminals of a vacuum tube during the passage of electricity just like that which occurs in a voltameter, and that this increases the obstacle to the discharge; but by an elaborate series of experiments we have proved that such is not the case under the conditions of the experiment. It is quite true that, after the connection between the battery and the terminals of the tube has been broken, there is a deflection of the needle when they are connected with a galvanometer, but we have shown that this is entirely due to a minute static charge proportionate to the capacity of the terminals.

Our experiments enable us to throw some light on another atmospheric electrical phenomenon—namely, the probable height of the aurora borealis, which the accompanying figure (Fig. 12) of a discharge roughly resembles. I will now pass the current of the whole 14,400 cells through the large tube 199, containing a residual charge of atmospheric air at a pressure of one millimetre, and you will perceive a carmine luminosity touching the positive pole, and reaching half-way down the tube. This reminds one of those ruddy glows frequently seen in auroral displays. Fig. 12 in the plate is copied from a photograph since taken in my laboratory of this appearance. Around the bright luminosity is a dark band which shuts off a portion of the fluorescence of

* Reprinted, by permission, from the *Proceedings* of the Royal Institution.

Digitized by Google

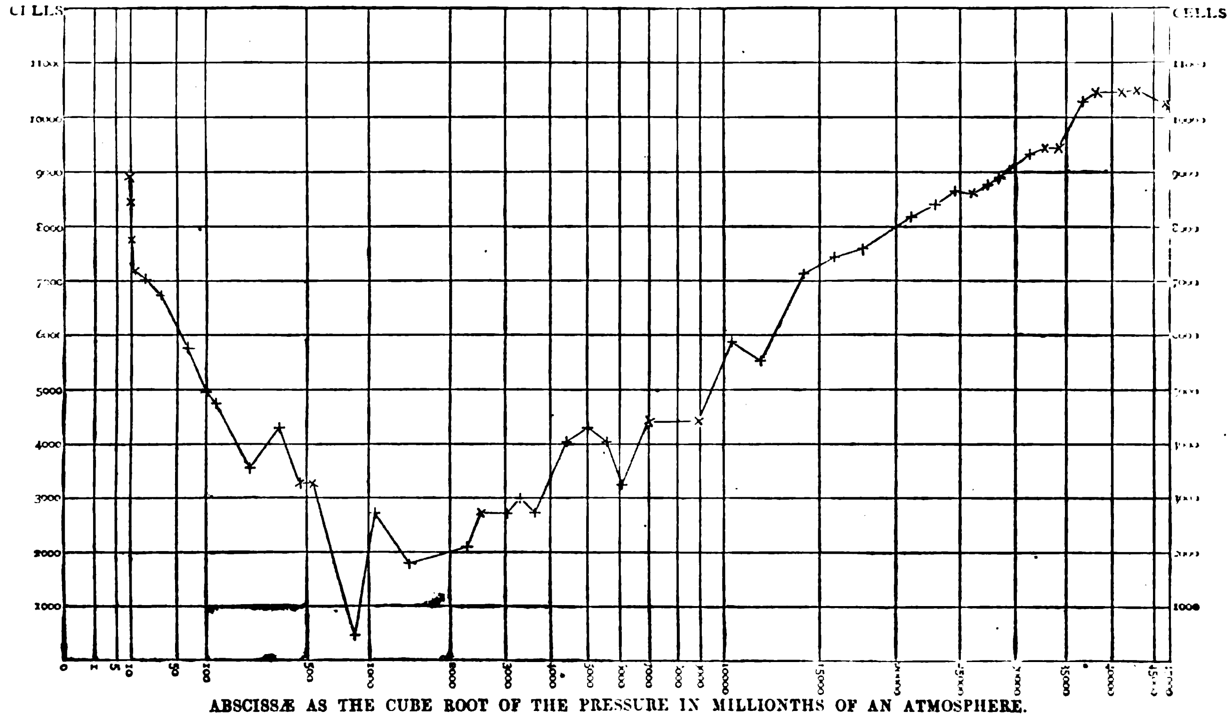
the glass tube, a blue fluorescence produced by the ruddy light of the luminosity, showing that around the luminosity there is an absorbent zone of less elevated temperature. Many estimates have been made from time to time of the height of auroræ, founded upon observations made by persons at a distance from each other, and supposed to be observing the same feature in the display; but it must be remarked that there is always much uncertainty in these estimates, from the difficulty of knowing whether the different observers have noticed the self-same streamer. Frequently very considerable altitudes have been assigned to these displays; for example, as much as 281 miles. We shall presently see that it is very improbable that any electrical discharge could occur at such a height. We have calculated from experiment that the pressure of least resistance for air is 0·397 millimetre, 498·6 millionths, and therefore in air it results that a maximum electric discharge, and consequent brilliancy, of the aurora, would occur at an elevation where the atmosphere has that pressure—namely, 37·67 miles. The greatest exhaust we have produced—and this has not been surpassed—is 0·000055 millimetre, 0·07 millionth, which is the pressure the atmosphere would have at 81·47 miles; and as 11,000 cells failed to produce a discharge even in hydrogen at this low pressure, it may be assumed that at this height the discharge would be considerably less brilliant than at 37·67 miles, should such occur.

At a height of 281 miles the atmosphere would only have a pressure of 0·0000000000000000000018 millimetre, or 0·000000000000000000024 millionth, and even at 124·15 miles in height the atmospheric pressure would be only 0·00000001 millimetre, or 0·00001 millionth. It is highly improbable that a display of aurora would occur at a height even of 124 miles, and it is difficult to conceive that an electrical potential could possibly exist necessary to overcome the enormous resistance that would be offered at 281 miles, the tenuity of the air being 54,000,000,000,000 (54 million million) times as great as at 124 miles.

Pressure mm.	Pressure M.	Height, miles.	Visible at miles.	Remarks.
0·00000001	0·000013	124·15	1061	No discharge could occur.
0·000055	0·07	81·47	860	Pale and faint.
0·379	499·0	37·67	585	Maximum brilliancy.
0·800	1053·0	33·96	555	Pale salmon.
1·000	1316·0	32·87	546	Salmon coloured.
1·500	1974·0	30·86	529	,, ,,
3·000	3947·0	27·42	499	Carmine.
20·660	27184·0	17·86	403	,,
62·000	81579·0	12·42	336	,,
118·700	156184·0	9·20	289	Full red.

There are some phenomena connected with the discharge from the voltaic battery which I will bring under notice before we proceed to the study of the discharge in vacuum tubes. I have already spoken of the difference in the length of the discharge between points and discs; and I have now to call your attention to the influence of the form of the point on the length of the spark. At first it would naturally be supposed that the longest discharge would occur with the sharpest point, but this is not the case; a great number of experiments with various forms of points have shown that a point in the form of a paraboloid gives the longest spark; and longer in the proportion 1·29 to 1 than one in the form of a cone of the same length and diameter at the base. It is difficult to account for this difference in the length of the spark, but it is evident the potential must be greater at the extremity of a parabolical point than it is at the extremity of a conical one (Fig. 13).

If a point and a disc be used together as terminals and the point be made alternately positive and negative, the spark is longest when the point is negative for low tensions



ABSCISSÆ AS THE CUBE ROOT OF THE PRESSURE IN MILLIONTHS OF AN ATMOSPHERE.

THE DISTANCES 0 TO 1, 0 TO 100, 0 TO 1000, &C., SHOW RELATIVELY THE NUMBER OF MOLECULES IN A GIVEN LINEAR SPACE.

FIG. 10.

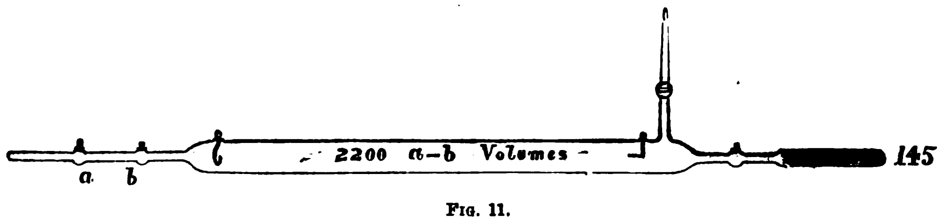


FIG. 11.

up to 8,000 cells, and longest when the point is positive beyond that number.

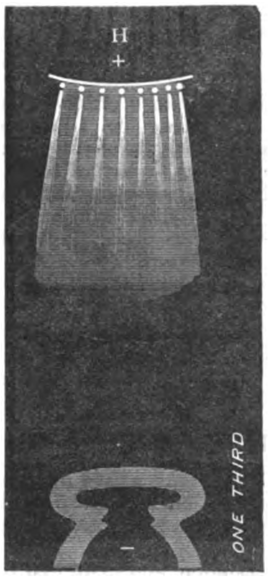

Fig. 12.

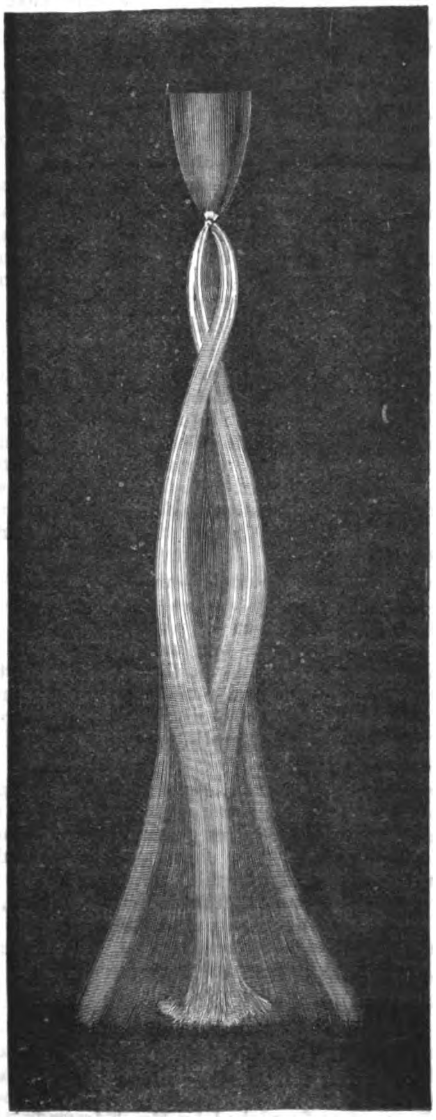

Fig. 14.

The nature of the metal makes not the slightest difference on the length of the spark, with one exception. Brass, copper, silver, steel, platinum, magnesium, and graphite, all give, under similar circumstances, precisely the same length of spark; aluminium, however, gives a spark longer in the proportion of five to four.

Before the spark jumps and the arc forms it is preceded by what we have called the streamer discharge. This is different in appearance at the positive and negative terminals. You

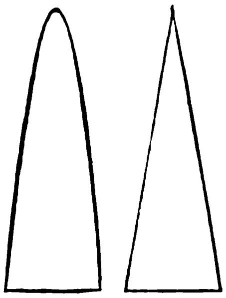

Fig. 13.

are not able to see the characteristics now that I produce the streamer discharge before you, but they are represented enlarged on the diagram, the terminals being supposed to be a point and a disc, and the point being made alternately positive and negative. When the point is positive the discharge takes the form of a series of twisted streamers (Fig. 14), when negative it is in the form of a brush (Fig. 15). The

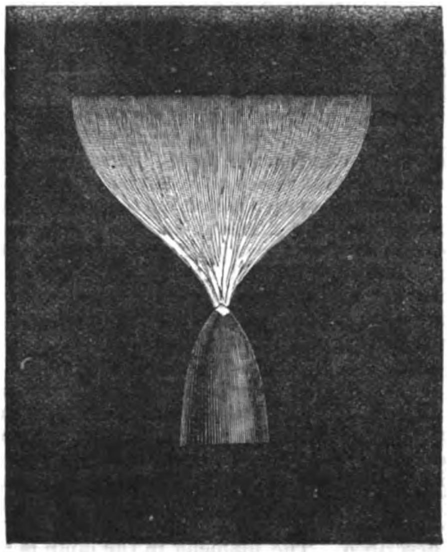

Fig. 15.

current which takes place in the form of streamers at a distance but a very little beyond the true striking distance—namely, that at which the arc is formed, is only the 1-2500th part of the current which passes with the arc, and this is only one half of that of the battery when short-circuited. When the streamer discharge is examined in a rotating mirror

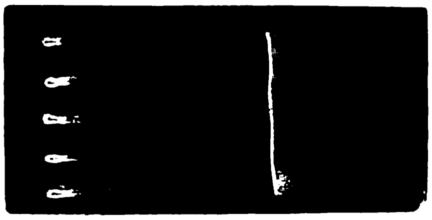

Fig. 16.

with a microscope suitably constructed, it is seen that the negative current is much the more continuous, for with the same velocity of the rotating mirror the positive discharge breaks up into a series of distinct images, whilst the light of the negative is spread out into a sheet, as you will see on the diagram (Fig. 16).

(TO BE CONTINUED.)

REPORT ON THE INCANDESCENT LAMPS EXHIBITED AT THE INTERNATIONAL EXPOSITION OF ELECTRICITY, PARIS, 1881.*

I.—Description of the Lamps.

The only lamps in the Exhibition which were purely incandescent in character were those of Edison and Maxim, in the United States Section, and those of Swan and Lane-Fox, in that of Great Britain. The idea represented in these lamps is essentially the same in all of them, the differences being, for the most part, details of construction. They all consist of a glass envelope more or less spherical in form, in which is enclosed a carbon loop, made of carbonised organic material, and supported upon wires of platinum sealed into the glass. The space in the interior of the lamp is very perfectly exhausted.

A. *The Edison Lamp.*—The Edison lamp is pear-shaped in form. The carbon filament is long and fine, and is bent into the shape of a U. It is made from Japanese bamboo, cut to the requisite size in a gauge. In section it is nearly square, being about 0·3 millimetre on a side, the ends being left considerably wider. The fibre is carbonised in moulds of nickel, and is attached to the conducting wires by copper, electrolytically deposited upon them.

B. *The Swan Lamp.*—The Swan lamp is globular in form, the neck being quite long. The carbon filament is made from cotton thread, parchmentised before carbonisation by treatment with strong sulphuric acid. The ends of this filament are very much thickened, and the loop has a double turn at the top. Its ends are clamped in a pair of metal holders, supported laterally by a stem of glass which rises through the neck to the base of the globe. Below, these holders are fastened to wires of platinum which pass through the glass.

C. *The Maxim Lamp.*—The Maxim lamp is also globular in form, but it has a short neck. Within the neck rises a hollow cylinder of glass, supporting upon its summit a column of blue enamel, through which pass the conducting wires of platinum which carry the carbon. The filament is made from cardboard cut by a punch into the form of an M. In section, therefore, it is rectangular, and several times as broad as it is thick. It is carbonised in a mould through which a current of coal gas is passed. After carbonisation the filament is placed in an attenuated atmosphere of hydrocarbon vapour and heated by the current. The vapour is decomposed, and its carbon is precipitated upon the filament. In this way not only are inequalities obliterated, but the resistance of the filaments may be equalised, and brought to any standard required.

D. *The Lane-Fox Lamp.*—The Lane-Fox lamp is ovoid in shape, the neck being in length intermediate between the two lamps last described. The carbon is in the form of a horse-shoe, and is circular in cross-section. It is made from the root of an Italian grass, largely used in France for making brooms. After carbonisation the filaments are classified according to their resistances. They are then heated in an atmosphere of coal gas, by which carbon is deposited upon them, as in the filaments of the lamps last described. The filament in the lamp is supported by platinum wires, to which it is attached by sleeves of carbon encircling both. These wires pass through tubes in the top of a hollow glass stem. Just below the extremities of these tubes are two small bulbs containing mercury, forming the contact between the platinum wire sealed into the glass above and the copper conductor which enters from below. These conductors are held in place by plaster, which fills the base of the lamp.

II.—Methods of Measurement.

The question to be determined was simply the efficiency of these lamps. The efficiency of a lamp is the ratio of energy produced to energy consumed, *i.e.*, the quantity of light given by the lamp for each horse-power of current which it consumes. The data required to calculate this efficiency may be obtained when the electromotive force of the current, the resistance of the lamp when giving its light, and its illuminating power have been determined.

1. *Electromotive Force.*—The electromotive force, or fall of potential through the lamp, was measured by Law's method. A suitable condenser was charged by being put in communication with a standard Daniell cell, and then discharged through a high resistance galvanometer, the deflection of the needle being noted. This condenser was then connected to the two wires of the lamp, and again discharged through the galvanometer, the deflection being made the same as before by means of a variable shunt connected with the galvanometer. Since, with a given condenser, the charges it receives are proportional to the potentials of the charging currents, and since the discharge deflections of a galvanometer represent the quantity of these charges, it follows that the electromotive forces are proportional to these discharge deflections. If, however, as in the present case, the discharge deflections are made equal by means of shunts, then the electromotive forces are proportional to the multiplying power of the shunts.

2. *Resistance.*—The resistance of the lamp, when giving its light, was obtained by making the lamp one side of a Wheatstone's bridge, through which the main current was flowing. The second and fourth sides were formed of fixed resistances of known value, and the third side of an adjustable resistance. When the bridge is balanced the product of the two fixed resistances, divided by the adjusted resistance, gives the resistance of the lamp at the given candle-power.

3. *Illuminating Power.*—The illuminating power of the lamp was measured on a Bunsen photometer. At one end of the bar was the lamp itself, at the other end two standard candles, placed nearly in line. The plane of the carbon filament was placed at 45 deg. to the length of the bar, and each lamp was measured at 16 and 32 candles.

III.—Apparatus Employed.

1. *Condenser.*—The condenser used in these measurements had a capacity of 1 microfarad, divided into sections of 0·4, 0·3, 0·2, and 0·1. The dielectric was paraffined mica, and the brasswork was supported on ebonite pillars. Made by Latimer Clark, Muirhead, and Co., London, and exhibited in their section at the exhibition.

2. *Galvanometer.*—The galvanometer was a Thomson double-coil astatic instrument, enclosed in a square case with glass sides. Measured resistance, 6,550 ohms. Used with lamp-stand and scale in the ordinary way. Made by Elliott Brothers, London.

3. *Standard Cell.*—An ordinary Daniell cell, the copper plate being immersed in a saturated solution of pure copper sulphate, contained in the porous cell, and the zinc plate amalgamated in a saturated solution of pure zinc sulphate in the outer jar. One of a battery of ten cells forming a part of the Edison exhibit.

4. *Resistance Coils.*—*(a)* A set of standard coils, measuring from 1 ohm to 5,000 ohms. All other resistances employed were standardised by these. Made by L. Clark, Muirhead and Co., and a part of their exhibit. *(b)* A set of coils used in the Wheatstone's bridge. Compared carefully with set *(a)*. These coils formed a part of the exhibit of Edison.

5. *Wheatstone's Bridge.*—Four conducting wires of large size arranged on the table in the form of a rhomb. A test galvanometer was inserted between the obtuse angles of the rhomb, and a pair of shunt wires from the main conductors were attached at the acute angles. The first side of the rhomb contained the lamp to be measured, standing in its place on the photometer; the second side contained a fixed resistance of 5 ohms; the third side contained a variable resistance (Resistance *b*); and the fourth side a fixed resistance of 950 ohms. This bridge formed a part of the Edison exhibit.

6. *Photometer.*—The photometer employed was of the Bunsen form, having a double bar, 80 inches long, graduated in inches and in candles. The disc was of paraffined paper, with a plain spot in the centre. The disc box was movable on rollers, and contained inclined mirrors to facilitate the adjustment. The candles used were of spermaceti, made by Sugg, of London, to burn 120 grains (7·776 grms.) per hour. The entire apparatus was surrounded with heavy black cloth. Also a part of the Edison exhibit.

7. *Dynamo-Electric Machine.*—An Edison 60-light machine was used to furnish the current required. In this machine the field magnets, which are very long and heavy, stand vertically. The field is maintained by a shunt current, regulated by an adjustable resistance in its circuit. The bobbin is wound on a cylinder like that of Siemens, from which it differs, however, in its details. Its resistance was only 0·03 ohm, and the current delivered, at a speed of 900 revolutions, had an electromotive force of 110 volts. A part of the Edison exhibit.

IV.—Resistance of Lamps Cold.

The resistance of the lamps cold was measured on a Wheatstone's bridge of the ordinary form and in the usual way. The Edison lamps were taken at random from the stock on hand. The Swan lamps were furnished by Mr. Edmunds, the Lane-Fox lamps by Mr. Stewart, and the Maxim lamps by Mr. Lockwood. Twenty-four of each were taken (except the Lane-Fox, of which only fifteen were furnished), and ten selected from these for the tests. The measurements of the Edison and Swan lamps were

* By an Experimental Committee, consisting of Messrs. George F. Barker, William Crookes, F.R.S., and others.

V.—Measurement of Efficiency.

1. *Experimental Results.*

A. *The Edison Lamp.*—In this measurement the entire condenser was employed. When charged with the standard cell and discharged through the galvanometer without shunt, a deflection of 310 scale divisions was obtained, as a mean of ten closely accordant experiments. The photometer readings were made by Mr. Crookes, the bridge readings by Major R. Y. Armstrong, and the galvanometer readings by Prof. G. F. Barker.

(*a*) *At* 16 *candles*—

Number of Lamp.	Photometer Reading.	Bridge Reading.	Galvanometer Reading.

D. *The Maxim Lamp.*—The entire condenser was used, as in the previous cases; but the deflection obtained was 315 divisions, owing probably to the higher temperature of the room. Photometer read by Mr. H. Crookes, bridge by Mr. Crookes, galvanometer by Prof. G. F. Barker.

E. *The Candle Record.*

Candle-power.	Loss in Grms.	Time in Mins.	Loss per Minute.
1. Edison Lamp.			
16	18·13	73	0·2483
32	21·22	84	0·2526
2. Swan Lamp.			
16 and 32	34·15	126	0·2695
3. Lane-Fox Lamp.			
16 and 32	40·70	153·75	0·2647
4. Maxim Lamp.			
16 and 32	26·90	104	0·2586

2. *Methods of Calculation.*

1. *Illuminating Power.*—The standard candle should burn 7·776 grms. spermaceti per hour, or 0·1296 grm. per minute. The two candles used should burn 0·2592 grm. per minute. The corrected candle power of the lamp, therefore, is obtained by the proportion: As 0·2592 is to the amount actually burned per minute, so is the observed candle power to the corrected candle power.

2. *Resistance* (*hot*).—From the theory of the Wheatstone bridge, the resistance of either side is equal to the product of the adjacent sides divided by the opposite side. In the bridge used for the measurement, the resistances in the two adjacent sides

Digitized by Google

were 950 and 5 ohms. Hence by dividing their product, 4750, by the reading of the variable resistance observed, the resistance of the lamp hot is obtained.

3. *Electromotive Force.*—In Law's method the electromotive forces are proportional to the multiplying power of the shunts employed. Since with the Daniell cell no shunt was used, the multiplying power of the shunt used with the lamp-current represented directly the electromotive force through the lamp, in terms of the standard cell. The multiplying power of a shunt is the sum of the galvanometer resistance and the shunt resistance, divided by the shunt resistance. In this case the resistance of the galvanometer was 6550 ohms. Hence if S represent the resistance of the shunt, obtained by experiment, $\frac{6550 + S}{S}$ will represent the electromotive force. Since the electromotive force of a Daniell cell is not 1 volt, as here assumed, but 1·079 volts, strict accuracy would require the figures given to be increased in that ratio. Moreover, the small error arising from the inductive action of the needle on the galvanometer-coils has been regarded as unimportant.

4. *Current.*—By the law of Ohm the current strength is the quotient of electromotive force by resistance. Dividing the electromotive force in volts by the resistance in ohms the current strength is obtained in Ampères.

5. *Electrical Energy.*—The work done by a current is proportional to the product of the square of the current-strength into the resistance of the circuit. Or, since the electromotive force is equal to the product of the current-strength by the resistance, the energy is represented by the product of the electromotive force in volts by the current-strength in Ampères. This gives the energy in Volt-Amperes.

6. *Mechanical Energy.*—Since an absolute unit of work is done per second by an absolute unit of electromotive force in a circuit of one absolute unit of resistance, 1 Volt-Ampère represents 10^7 absolute units of mechanical work per second, or 0·10192 kilogrm.-metre. By multiplying the Volt-Amperes by 0·10192, the product is the mechanical work done in the lamp in kilogrm.-metres.

7. *Lamps per Horse-power of Current.*—One horse-power is 75 kilogrm.-metres per second. By dividing 75, therefore, by the number of kilogrm.-metres of work done in the lamp per second, the quotient is the number of such lamps maintained by a horse-power of current.

8. *Candles per Horse-power of Current.*—The number of candle-lights per horse-power of current is obtained, of course, by multiplying the number of lamps per horse-power of current by the corrected candle-power of each.

9. *Normal Lamps per Horse-power of Current.*—Conversely, by dividing the number of candles per horse-power of current by the normal value of the lamp in standard candles (in the present case 16 or 32), the number of normal lamps per horse-power of current is obtained.

VI.—Conclusions.

The following conclusions seem to be sustained by the results which have now been given:—

1st.—The maximum efficiency of incandescent lamps in the present state of the subject, and within the experimental limits of this investigation, cannot be assumed to exceed 300 candle-lights per horse-power of current.

2nd.—The economy of all lamps of this kind is greater at high than at low incandescence.

3rd.—The economy of light-production is greater in high resistance lamps than in those of low resistance, thus agreeing with the economy of distribution.

4th.—The relative efficiency of the four lamps examined, expressed in Carcel burners of 7·4 spermaceti candles each, produced by one horse-power of current, is as follows:—(A.) At 16 candles: Edison, 26·5; Swan, 24; Lane-Fox, 23·5; and Maxim, 20·4. (B.) At 32 candles: Edison, 41·5; Lane-Fox, 37·4; Swan, 35·5; and Maxim, 32·4. To double the light given by these lamps the current-energy was increased, for the Maxim and Lane-Fox lamps, 26 per cent; for the Edison lamp, 28 per cent: and for the Swan lamp, 37 per cent.

Telegraphic Conference.—A conference of delegates of several of the West India Colonies has met at Barbadoes, and proposed a scheme for improving telegraphic communication between the West Indies and Great Britain.

THE ELECTRIC LIGHT AS A LUXURY.

For want of substantial argument the journals devoted to gas lighting interests have latterly taken to disparaging their detested rival by what, in the social relations of life, would be called flatulent sermonising. The electric lighting companies are immoral and unscrupulous speculators; the evidence relating to the new light is fraudulently misstated or suppressed; the light itself is an impostor, and the people who favour it are wantonly guilty of an attack upon property. Moreover, we are informed that the electric light is not needed; it is a superfluity, a wasteful expenditure of light, an infraction of the laws of nature, "tending to turn night into day"—is, in short, a luxury of the sinful sort which pious vestries and wealthy citizens alike should religiously eschew.

As a rule, we are not enamoured of the *tu quoque* mode of reasoning; but here is an occasion when, if ever, the "you're another" method is the best and, perhaps, the only argument possible. Gas is itself a luxury. Not so many years ago it was an unobtainable luxury. Compared with oil-lamps in the streets, it was and is a blessed luxury; in some situations it is still a luxury for the distant future only; while in many others which "never are, but always to be, blessed" we are content to think that the luxury of gas can never pollute them. Pope must have had the gas champions in his prophetic mind when he made "Whatever is, is right" to rhyme with "Nature's light." Evidently, in their estimation, gas is the light referred to; and, as gas *is*, gas is right. We do not dispute the proposition; we only want to remind our critics, as the self same poet reminds his own, that

> . . . This world, 'tis true,
> Was made for Cæsar—but for Titus too.

If the electric light is a luxury it is a clean and wholesome luxury, which is, to put it mildly, more than can always be said for gas; and even should the world not tire of gas, as it did of Cæsar, there is plenty of room for the electric light, as there was for Titus, "whose virtue" (another proof of what Pope must have been dreaming of) "sighed to lose a day!"

Seriously, however, we are prepared to accept this challenge as to the electric light being a luxury. This is an age of luxury, and an age quite able to pay for what it likes. We cannot pronounce with confidence upon the economics of asphalted roadways or of high-heeled shoes, but the public pay for them and presumably like them; the cost is a minor matter, the luxuries, such as they are, outweighing all other considerations. It is certain that ladies do not consult the interests of virtuous cordwainers who stick to low heels, nor have the horses been questioned as to their private opinion about asphalte. In all human probability the public will be equally oblivious as to the moralities and the conveniences of gas manufacturers. If the electric light is preferred it will be demanded, and none the less so for its costing a trifle more than gas.

We put the case in this wise not as admitting that the cost of gas is, or at all events, need be, less than that of electricity, but merely to show that we by no means rely upon the superior economy of the new mode of lighting. We have repeatedly deprecated the reticence which has hitherto prevailed in respect to the cost of electric lighting. It has come to be acknowledged that what is charged for it is no criterion of what it actually costs. The reason is intelligible, but it is damaging, and is altogether a mistaken policy. The public, if frankly taken into confidence, would be quite able to understand and make allowances for the unavoidable expenditures on experimental installations confined to limited areas; and we feel sure that the result would have been preferable to the state of things described by the President of the Royal Society in his evidence before the parliamentary committee. "Nobody," said Mr. Spottiswoode, "knows accurately [what the cost of producing electricity is], and those who might know, certainly will not divulge at present." The real reason is because "those who know" know also that different methods differ in cost, and nobody is yet quite sure whose method is the cheapest. But the general public, and especially the gas shareholding public, are apt to construe silence as proof of a bad case, whereas it is only evidence of caution among various competitors. In this stage of the competition there would probably be the same amount of uncertainty as to actual cost even were the highest estimate known to be much lower than what is charged for gas.

In some quarters, however, there are signs that this barrier of silence is being broken down. One or two of the parliamentary witnesses—notably the one representing Mr. Edison—went into explicit figures which showed that he at all events had no apprehensions on the score of expense. If these calculations are borne out by practical experience—and there is reasonable ground for believing that they will be—the prospects of electric lighting even as an economical competitor with gas are well assured. Several letters from responsible persons who have lately installed the light on their own account, and communicated the results to the newspapers, tell the same story. The high authority whose words we quoted above gave it as his opinion that the cost was fairly comparable with that of gas even when, as in his own case, the electric light is introduced into a single establishment and on a small scale. To Mr. Spottiswoode, however, its relative cost was not a matter of first moment; he liked the light, it saved his pictures and books from disfigurement, and did not befoul the atmosphere. He

Digitized by Google

thought he paid no more for it than for gas, but if he did he would willingly incur the trifling extra expense for the—luxury. This we may safely conjecture will be the general verdict in the long run, and all the sermonising in the world will not, in that case, prevent the latest boon of science becoming not merely a luxury but a necessary of civilised life.

CORRESPONDENCE.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Harbord's letter to you is a most amusing one. From beginning to end it is a tissue of denials, without a single word of proof to support these denials. It does not require a wise man to write such a letter. When fixing a man of Mr. Harbord's proclivities—for unsupported assertion—it does not do to give him much rope; I shall, therefore, notice only a part of his letter. He writes, "The bending of the two gas flames in one direction does not disprove induction; it only shows the passage of a current, and is no evidence of electrical matter passing through the glass of the jar." This passage is important in two respects. First, he admits that the bending of a gas flame does indicate the direction in which a current of electricity moves. Second, as the two flames are bent both in the same direction, therefore the currents of electricity they indicate must both move in the same direction. As Mr. Harbord is an out and out supporter of the theory of two electricities, before proceeding further it is necessary for me to keep my foundation clear by noticing the fact that I have in your pages had discussions with Mr. J. E. H. Gordon and Prof. Silvanus P. Thompson about the electricity which comes from a frictional machine. These gentlemen maintained in their published writings that one kind of electricity is given out at the prime conductor of a frictional machine, and that another kind of electricity is given out at the cushion of the machine. This I denied, and produced experimental proof showing that only one electricity passes through a frictional electrical machine, namely, that electricity goes from the ground up the chain of the cushion, and then from the cushion to the glass, and from that to the prime conductor, where it is delivered off. Mr. Gordon and Professor Thompson were unable to rebut the proofs I gave in support of the foregoing fact, but when Dr. Shettle took to writing in your pages, under the title "What is Electricity?" in his first letter, Vol. VIII., page 199, he wrote:—"By way of recapitulation, I believe I may say that I have thus shown . . . . that in static electricity the force developed by friction must be equal in the two forms of matter subjected to the process, and that force originated by motion in two directions must itself partake of the two directions." This is a direct contradiction in words by Dr. Shettle of the experimental proof which I gave in your columns concerning the action of the frictional machine. The foregoing passage of Dr. Shettle's is an assertion that one kind of force or electricity is delivered at the prime conductor of a frictional machine, and that another kind of force or electricity is delivered at the cushion of the machine. This contradiction by Dr. Shettle is an unsupported assumption that my experimental proof is wrong, by which I have shown that there is only one electricity passing through the frictional machine. This unsupported assumption he gives as a foundation of his theory of electricity without giving one atom of proof that two currents of force or electricity issue from a frictional machine. From the foregoing reason Dr. Shettle's theory of electricity is worthless, because he has founded it on an assumption which is false. Having thus made plain the foundation for my argument with Mr. Harbord, I now proceed. (See page 62, Fig. 6.) The electricity which comes from the ball A on the prime conductor of the frictional machine bends the flame B towards the right hand, and it also causes the flame F to move toward the right hand; and these flames teach us that the currents of electricity which move them do also move in the same direction; and as the flame B is bent to the right hand by the electricity coming from the ball A and passing into the Leyden jar D it is manifest that the bending of the flame F to the right hand indicates that a current of electricity is moving from the outside of the Leyden jar D, through the wire E, and passing on to the ball H. Now, the question to be solved is, Where does this current of electricity come from which passes from E to H? When the Leyden jar D is charged in the usual way, the motion of the flame F continues in the same direction as the flame B until the jar D has received its full charge, then immediately on this taking place the motion of the flame F stops, and the flame stands upright. Will Mr. Harbord explain the cause of this, when he has taken along with it the following fact. When the Leyden jar is being charged while the paraffin plug and wire are placed in its mouth (see Fig. 7, page 63), the flames B and F both move to the right hand, but during this arrangement of the apparatus there is no period ever reached when the flame F will cease to bend toward the right hand; it will continue to move in this direction as long as electricity is passed into the interior of the jar D. If the electricity which thus continuously moves the flame F to the right hand does not come from the interior of the jar and through the glass will Mr. Harbord give in your columns experimental proof as to where the said electricity does come from? I may add that it is a well-known fact that there are some kinds of glass of which if bottles are made it is impossible to convert these bottles into Leyden jars, because the glass allows all the electricity to pass through it. In Mr. J. E. H. Gordon's "Physical Treatise on Electricity and Magnetism," Vol. II., pages 120—123, he gives the particulars of experiments made in 1877 with four kinds of glass which had been made a few weeks before. He tested the capacity of these four kinds of glass with reference to electricity, and eighteen months after he again tested with electricity these same samples of glass, and found that the eighteen months had made a difference of 25 per cent. in the capacity of these samples of glass for electricity. Seeing from all these facts that electricity can go through some kinds of glass with perfect freedom, while it goes with difficulty through other kinds of glass, and that age affects the capacity of glass in this respect, I maintain that the only rational conclusion which can be come to on this subject is that the atoms of electricity must be of a definite size, whereas the pores in glass are not of a definite size. In new glass the pores are large, and in old glass they are small. The contraction of the pores of glass may arise from two causes—*first*, the shrinkage of the glass by age; *second*, the filling up of the pores of the glass by extraneous matter. That extraneous matter does affect the pores of glass is manifest by the discovery of Professor Jenkins, that when glass has lost its power of insulating electricity the power of insulation may be restored to it by "the glass being immersed for twenty-four hours in distilled water, and be allowed to dry for the same length of time without rubbing it with anything whatever." This discovery has been successfully used by Professor Carlo Marangoni for the restoration of the glass plates of Holtz machines which had lost their power of insulation through long use. If the difference of the size of the pores of glass is the reason why some kinds of glass insulate electricity, while other kinds of glass allow electricity to pass freely through them, then the size of the atoms of electricity are in reality the means by which we test the size of the pores of a piece of glass, and hence electricity must be matter and not force, because matter is divisable into atoms, but force cannot be divided into atoms.

I now turn to Dr. Shettle. In his first letter to you, under the title "What is Electricity?" he attempted to strike a blow at some of the contents of my previous letters published in your columns. By his doing so he threw down the gauntlet to me. I took it up and answered him. Is it to be a matter of history, recorded in the pages of *The Electrician*, that Dr. Shettle challenged an opponent and then shrank

Digitized by Google

from the contest when he found he could not answer without compromising his own statements about facts ?—Yours, &c.,
JAMES JOHNSTONE.

Experiment Rooms, 1, James-square,
Edinburgh, June 12, 1882.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent has taken a vast amount of trouble to prove that a current of electricity moves in a given direction, and concludes his letter by stating, "If its contents do not convince Dr. Shettle that he is wrong in maintaining that electricity is energy and not matter, I may in another letter enter into details in criticising Dr. Shettle's theory of electricity, in the explanation of which he has used a great flow of scientific words, which result in the confounding of some scientific facts." After declining to enter upon a consideration of Mr. Johnstone's scientific facts, as I have done, I should not have deemed it necessary to write more now were it not to relieve Mr. Johnstone from some errors into which he appears to have fallen. 1st. I have never stated that electricity is energy and not matter, or matter and not energy; but that, secondly, electricity is a *peculiar* condition of matter, the energy of which, when in motion—other things being equal—is in proportion to the strength of the current. Mr. Johnstone stated that electricity is a *peculiar kind of matter*. In this view I cannot concur, but I have no objection to any amount of criticism or to Mr. Johnstone's maintaining his opinion if he thinks proper to do so.—Yours, &c.,
R. S. SHETTLE.

SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Now that much attention is being given to the subject of storage of energy it may be as well to point out that the problem to be solved is more of a chemical than an electrical nature, for as a matter of fact in all so-called accumulators of electric force it is always chemical work that is done, and which by being undone, so to say, gives out force corresponding to that expended in the original primary charging of the secondary batteries.

From the laborious investigations of M. Planté and others it is pretty certain that lead is the most suitable metal for employment in the construction of accumulators, and since peroxide of lead is the other active substance formed by charging the accumulators, it becomes a question of what form of leads can be most profitably employed, and how the red lead or peroxide of lead can be best placed as against the metallic lead. Before the use of secondary batteries can become at all wide-spread it is essential that great improvements must be made upon the forms at present before the public, and in calling attention to a new accumulator which is said to have excited considerable interest already, we can only make general remarks, because, so far, the details are not made known, although the time is fast drawing near when the final specification of the patentees must be deposited.

It is said, then, that in the new Donnithorne battery, as it is termed, the lead which is employed is in the very best form, chemically speaking; that is to say, it presents the greatest possible surface while presenting corresponding lightness in character. Then, again, no felt or other destructible material is used in the battery, but an altogether new and simple plan is adopted of supporting the red lead or other lead compound to be employed. The battery is also provided with a simple mechanical contrivance, whereby loss of energy is said to be avoided when the accumulator is not in active use. As compared with the batteries bearing the names of M. Faure and Messrs. Sellon and Volckmar, it is said that the Donnithorne battery is very much lighter, is more portable, less costly, and considerably more receptive in character. There are at least three important plans of constructing the battery in question, and if the opinion of Mr. C. T. Kingzett—the chemist who has been professionally consulted by the patentees throughout—should be confirmed by that of other authorities, the new departure promises well for the development of electric lighting for domestic and other purposes.—Yours, &c.,
X.

CURATIVE ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Desmond FitzGerald says:—"When, however, the animal body is made to form part of a magnetic circuit, not only is it impossible to demonstrate the production of any physiological effect, even with the most powerful magnets, but, if we choose to assume that such effects occur, their production must be that of the vascular or circulatory system, or, in other words, that the arterial and venous flow must be more or less impeded." In my reply to Mr. Donovan I have pointed out that the laws governing magneto-electricity are bound to hold good, whether in a living body or out of it, and to this I adhere; but, to make the fact still more patent to Mr. Desmond FitzGerald, I would point out that the power generated under magneto-electricity depends upon the power of the moving magnets. In the case in question it is impossible to deny that the polarity of the blood corpuscles is increased by the artificial magnets. But there are, notwithstanding, several reasons why this increased polarity of the blood corpuscles should not slow the circulation as suggested, amongst which I would name—1st. the shape of the corpuscles, which are bi-concave; 2nd. the low polarity, which is manifested principally on the surface of the discs, as shown by the manner in which they cohere by their flat sides when at rest and undergoing the process of coagulation; 3rd. the rapid motion to which they are subjected from the action of the heart, for it has been shown that the blood makes the circulation of the system in about one minute; 4th. under such circumstances, by the laws of magneto-electricity, the circulation ought to be rendered more rapid, for the nerve current must be in proportion to the polarity of the blood corpuscles, and the action of the heart to the strength of the nerve current.

I do not dispute the influence of flannel in stimulating the skin by friction, and so favouring vital action, but I do mean to assert that these magnetic appliances produce a like friction in the interior of the body, and in proportion to the increased amount of friction they are productive of comparatively greater results.—Yours, &c., R. S. SHETTLE.

Reading, June 3, 1882.

NOTES ON THE CRYSTAL PALACE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The editorial note appended to my letter in your last issue with reference to the necessity for taking into consideration the class of carbons used hardly accords with the result of my conclusions, as you will see on closer examination.

In the first place, writing from memory, I believe I was informed that those used in the Pilsen lamp were made by Messrs. Johnson and Phillips, as were also those used by the British Electric Light Company in their Brockie lamp. Again, do not Messrs. Siemens manufacture their own?

On the other hand, Mr. Crompton is said to burn Carré carbons exclusively, and in his treatise says that those made by the Brush Company are superior in most respects to any others.

It is, therefore, apparent that my observations do not tend to show that the best French carbons give the best light; but, under any circumstances, it is no unfairness to suppose that each competitor was doing his utmost to outpace his rivals in the race for popular favour, and I consider that I was perfectly justified in assuming that each system was shown to the best advantage.

In reply to your correspondent, "X.Y.Z.," I cannot do better than refer him to your contemporary, the *Telegraphic Journal*, of June 10, where he will find the Self-Generating Company treated to an exhaustive criticism; and I may add that I also wrote to the secretary, a Mr. Farie, for an explanation of the extraordinary statements which appeared in

Digitized by Google

their prospectus, but the only fact elicited was that the "self-generator" was a galvanic battery "specially designed for durability," further information being refused on the ground that the specification had not been filed.—Yours, &c.,

G. A. Moore.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: On reading your correspondent's notes on the different systems at the Electrical Exhibition, I could not help thinking how different things would look if further details were given respecting the exhibits he criticised.

As I am living near the Palace, and visited it nearly every evening during the exhibition, perhaps you will afford me space to add a little more, from an outsider's point of view. I must add that I not only *saw* the things at work, but made it my business to become tolerably acquainted with the working of most of them.

The Pilsen, I believe, was the steadiest lamp burning; but was it as economical as others—that is, did it give out in light the same amount per horse-power as other systems? I rather doubt it.

Again, your correspondent takes Siemens, and, considering only its steadiness, is greatly misled—that is, from a buyer's point of view. As an instance of this, take the far greater cost of this system compared with another in lighting up the City.

We are told Jablochkoff can still compete with a great many. In changes of colour, I presume he means; for if he saw the lights in the gallery and other parts of the building he would think, with others, they would be eminently suited for outdoor use on a firework night. Now, as to the disappointment in the Crompton lamp I must say a little. I, too, was somewhat disappointed after seeing the lamps burn so well at the earlier part of the exhibition; and having the curiosity to inquire as to the cause found out only too good a reason, for the machines were running at nearly 200 revolutions per minute too little. The large engine which was driving this and five other companies' machines was overloaded, and, consequently, did not keep up its speed.

The Joel is a very pleasant light to look at, but is supposed to be rather dear, when you can get 500 candle-power from an arc light with half horse-power, and from the semi-incandescent you get something like 200.

As to the Bürgin machine, I have seen it working many a time, and invariably admired its compactness and look of durability; but why it should be supposed to absorb more power in proportion to its work than other machines I fail to see.

I may here add, in closing these remarks, that I have been informed that Messrs. Siemens prefer the upright form of their machine on account of certain induction which is experienced when the machine is lying flat on the ground.—Yours, &c.,

A Closer Observer.

Gipsy Hill, June 14, 1882.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have read with interest the letter from Mr. G. A. Moore in your issue of the 10th inst. I concur in several of his opinions, particularly those expressed in the first and seventh of his notes, where he states the Pilsen lamp to be the steadiest and the Brush light to be trying to the sight. It is rather, however, with regard to the seventh note that I should like to make a few remarks. Mr. Moore there states that "the price of all dynamo machines of the present day is altogether too utter to tempt the majority of persons to whom the light would be otherwise an advantage." This opinion one can hardly fail to agree with, and I think it might well have been extended to the arc lamps. I have myself heard it stated by several large mill owners and manufacturers in the north of England that they should adopt the light in their works but for the cost of the dynamos and lamps. It is, I think, in this question of cost that now lies the solving of the problem whether electricity will supersede gas. It has been amply demonstrated that the electric light is a good and serviceable light. Can it be produced at a sufficiently reasonable cost to admit of its general adoption?

Now, a great many different systems have recently been brought out by companies floated for the purpose, so many, in fact, as to bewilder intending investors and employers of the light. I have interested myself in reading the prospectuses of all those companies, in the hope of ascertaining which is the best and cheapest, and it has struck me as being very significant that in most cases they make hardly any mention of the all-important question of cost. A reference to the current value of the Anglo-American Brush Company's shares, and to the Government report upon that company's lighting of the South Kensington Museum, appears to be considered by many new companies a sufficient recommendation of their own system. Others content themselves with a vague and general statement that their light is remarkable for its efficiency, cheapness, &c. Now, these credentials are, in my opinion, wholly insufficient and undeserving of the public confidence and support.

There is one exception to the above criticism, and that is in the case of the Laing Electric Light and Power Company. This company's prospectus publishes *in extenso* (not mere extracts from) Professors Ayrton and Perry's reports upon their system, and, what is more important, gives the actual manufacturing cost of their machines and lamps.

A dynamo, together with twenty-one arc lamps each, to be of an intensity of 500 actual (upwards of 1,500 nominal) candle-power is stated to cost £163 16s. 2d. to manufacture, 50 per cent. for profit added to which makes a total of £245 14s. 3d. I see by the Hammond Company's (Brush system) printed price list that their charge for a dynamo and sixteen lamps of 2,000 nominal (or about 500 actual) candle-power is £656. The balance is, therefore, enormously in favour of the Laing Company, and if their light, which is I believe as yet comparatively unknown in this country, proves to be up to the mark the inventor may fairly claim to have made a great stride of improvement in electric lighting. I have made the above comparison with the Brush system, because it has hitherto been the most successful, and also because it is difficult to ascertain what many of the other systems actually do cost. I suspect, however, they would be more explicit on the point were they able to show such favourable figures as those given by the Laing Company. I would add that I do not consider such lighting as that hitherto carried on in the City of London or the South Kensington Museum to be necessarily a fair criterion of the cost of lighting. I should like to know how much profit has been made upon those contracts.—Yours, &c., X. Y. Z.

M. PHILIPPART AND MR. VOLCKMAR.

We have received from Mr. Volckmar the following copy of a letter which has been addressed to him by M. Philippart:—

[Copy.]

"446, Strand, W.C.,
"June 7th, 1882.

"Dear Sir: I acknowledge before we enter into our conventions that you have given me full explanations upon the circumstances which have been on my part the object of personal attacks affecting your honour; I, therefore, retract every expression and every accusation which, publicly or otherwise, have been used by myself or on my behalf, which could reflect in any way upon your honour.

"From to-day we, on both sides, loyally put an end to any dispute or lawsuit between us.—Yours faithfully,

(Signed) "S. Philippart.

"Monsieur E. Volckmar,
"74, Hatton-garden."

Blasting by Electricity.—Electricity is now employed in firing the charges in blasting stone in the quarries at Huntington, Indiana, U.S.A., and it is estimated that a saving of 50 per cent. is effected over the old plan.

Digitized by Google

THE CRYSTAL PALACE EXHIBITION.

The Post Office Telegraph Exhibit.

Electric telegraphy is undoubtedly the most useful application of electric science. Though the name is familiar to all classes of people, both young and old, only a few know more than that the wires they have seen are the mediums of secret communications. We have heard many exclamations of surprise from visitors at the Crystal Palace during the working of telegraphic instruments, hence we are of opinion that such an exhibit as that so admirably furnished by the Government must have done a large amount of good. Anything which aids the education of a people must surely benefit the whole nation. Prior to the beginning of this century several attempts were made to transmit letters and words afar off by means of frictional electricity, but all such experiments failed. The

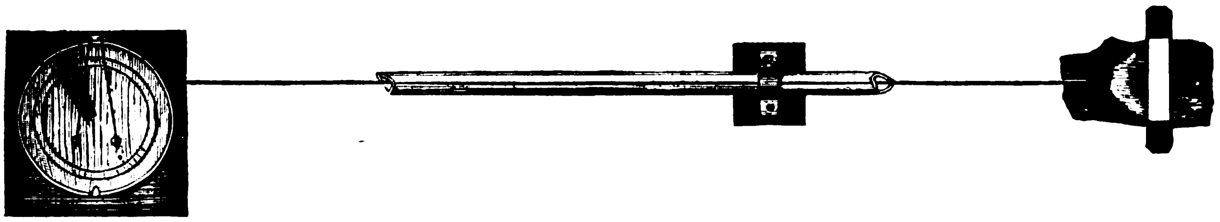

Fig. 1.—Ronald's Telegraph. Showing Specimen Exhibited.

discovery of *galvanic* or *voltaic* electricity was destined to produce a marked change, without which practical electric telegraphy would be impossible. It is curious to find that new discoveries rarely meet with ready acceptance. In "Bryan's Lectures on Natural Philosophy," published in 1806, the author, after debating upon frictional electricity, refers to galvanic effects, and says:—" Some persons suppose

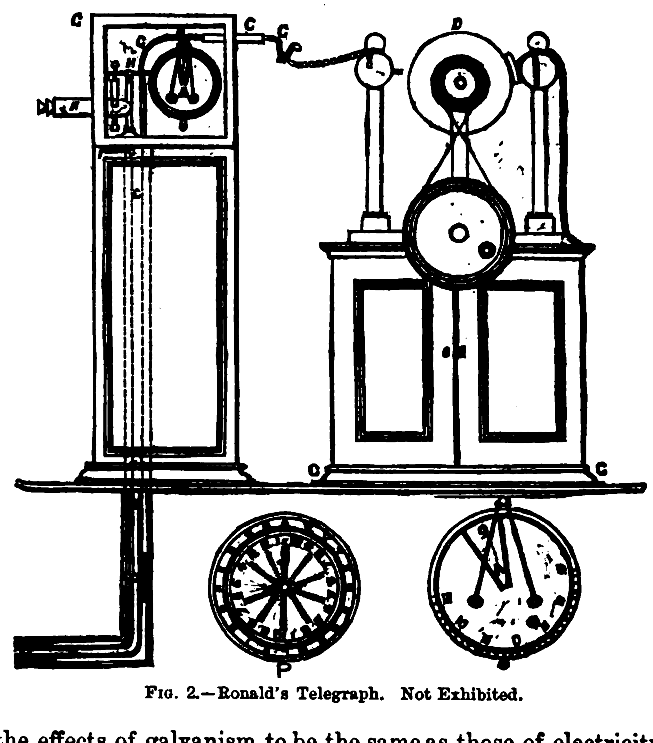

Fig. 2.—Ronald's Telegraph. Not Exhibited.

the effects of galvanism to be the same as those of electricity, though their mode of operation differs considerably. . . . . . Many cruel experiments have been tried in this science, at which human nature shudders. . . . . It is a science I am not desirous of cultivating." Now, the electrical power called *frictional electricity,* though small in quantity, is of high intensity. In fact its condition, in comparison with that developed by the galvanic battery, may be represented by very high pressure steam compared with low pressure steam, or perhaps, better still, water under a high head of pressure compared with water under a low head. It is evidently much more easy to make joints and pipes capable of conveying the low pressure water than that at high pressure; and just so with the two states of electricity, the degree of insulation of the conducting wires which will perfectly suffice for the low intensity, or voltaic currents, would provide no insulation at all for the high intensity or frictional charges. The invention, therefore, of the galvanic battery constituted a most important era in electrical applications.

The Post Office apparatus, past and present, occupied two long counters, and was arranged in chronological order by Mr. J. W. Willmot. This arrangement enabled visitors to trace with ease the development of practical telegraphy from the year 1816. Unfortunately the descriptions in the catalogue did not follow the same order; but each section of apparatus was clearly indicated by bold lettering on the tables. The whole was in charge of Messrs. Probert and A. Graves, of the Postal Telegraph Department.

At one end of the exhibit might be noticed an abstract from the *Chemist*, 8th January, 1825, on the "Motion of the Electric Fluid," in which the writer, after commenting on Mr. Barlow's investigation as to the diminution of electromagnetic effects by increased resistance, concludes with this phrase, "*Hence, the idea of making electric telegraphs is quite chimerical.*" Following on this was a small case, kindly lent by Mr. Latimer Clark, containing "the earliest existing specimen of an electric telegraph" (so the printed notice stated)—that of Ronalds, 1816 (Figs. 1 & 2). We understand that Ronalds used the divergence and collapse of pith balls as signals to direct the attention of an observer to the letter, which, at the moment of such divergence or collapse, was in view through a small opening in a clock dial. At the two

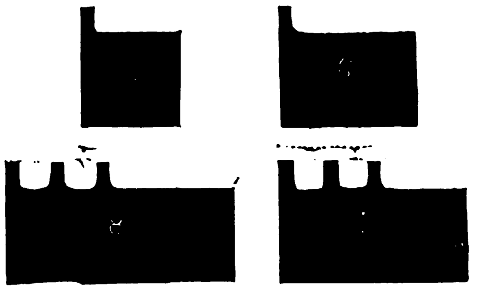

Fig. 3.—Morse's Type for the Electro-Magnetic Telegraph.

ends of the line of communication were placed clocks, going with absolute isochronism, and carrying light discs bearing letters around their circumference. Thus the clocks being started with like signals, visible through an opening in a screen or dial placed before the discs, would, so long as they went perfectly together, continue to show in succession signal after signal simultaneously. The attendant at one station would, therefore, know that when any letter was visible on his clock, the same letter (if the clocks went right) would be visible on the other, and he could, therefore, by waiting for the appearance of the letter required on his dial, call the attention of his correspondent to this letter by suddenly charging or discharging the wire, and thus producing the divergence or collapse of the pith balls. Ronalds, however, employed frictional electricity of high intensity, and for the reason already stated this system could not have become practicable. Fig. 1 gives details of the system, showing the line wire, pith balls, &c., and is a facsimile of the specimen

Digitized by Google

exhibited. Fig. 2 shows the instrument, together with the mode of obtaining the current, &c. We described this apparatus in Vol. VIII., p. 341, in detail. P is a brass plate divided into 20 equal parts, fitted on the seconds arbor of a clock. Each division is marked by a figure, a letter, and a preparatory sign. The figures are divided into two series, 1 to 10, and the letters are arranged alphabetically, leaving out I, Q, U, W, X, and Z. Before or over this disc is fixed another brass plate capable of being moved by the hand round its centre, which had an aperature of such dimensions that whilst P was carried round by the motion of the clock, only one of the letters, &c., can be seen at the same time. In front of this pair of plates is suspended an electrometer of Canton's pith balls. D is the frictional machine for generating the current, CC conductors, G instrument case, E the insulated conductors. The apparatus shown in Fig. 2 was not exhibited at the Crystal Palace. Mr. Latimer Clark's case also contains Professor Morse's autograph, his small glazed porcelain in-

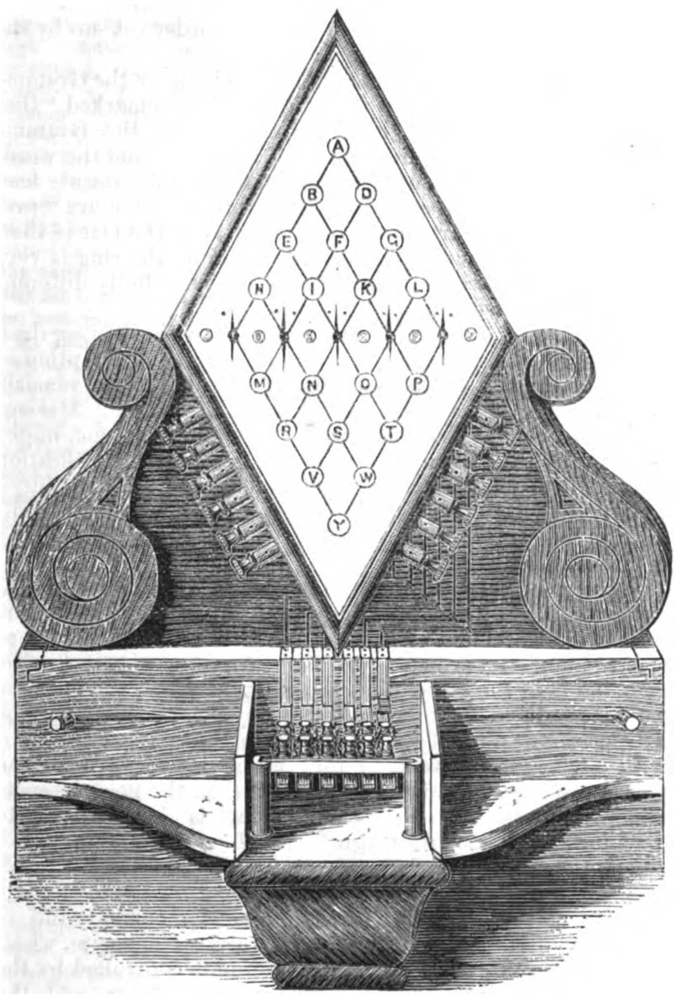

FIG. 4.—Original Five-Needle Instrument of Wheatstone.

sulators, and his "original type cast in December, 1832, for the Electro Magnetic Telegraph" (Fig. 3). Morse was the first to introduce a recording telegraph system. His first thoughts, however, were that accurate transmission could only be effected by automatic means, hence, type of the sort shown above were set up in a composing stick, and urged forward by an endless band, so that the projections of the type successively lifted one end of a lever, causing intermittent currents to actuate a suspended lever, carrying a pencil over a propelled band of paper. Zig-zag lines appeared on the ribbon, the points and spaces of which represented numbers, and the numbers indicated words. A telegraphic dictionary was necessary for this system. This rude invention was publicly exhibited for the first time on September 2nd, 1837, and worked successfully through one third of a mile of wire.

Wheatstone's five needle instrument of 1837 (Fig. 4) stands in striking contrast with his later automatic system on the opposite counter. The former required *five* wires for its operation, and was slow in its action, whereas the latter needs one wire only, and can signal at varying rates from 10 to 200 words per minute. The five-needle instrument was the earliest form used for publicly demonstrating the practicability of an electric telegraph. Two such instruments were in communication between Euston and Camden Town on the London and Birmingham Railway in 1837.

Mr. Latimer Clark in his inaugural address before the Society of Telegraph Engineers, gave the following account of the first trial of this system :—

"Late in the evening of June 25, 1837, in a dingy room near the booking office at Euston-square, by the light of a flaring dip candle, which dimly illuminated the surrounding darkness, sat the inventor Wheatstone, with a beating pulse and a heart full of hope. In another small room at the Camden Town Station, where the wires terminated, sat Mr. W. Fothergill Cooke, his co-patentee, and, among others, two witnesses well known to fame, Mr. Charles Fox and Mr. Stephenson. These gentlemen listened to the first word spelt by that trembling tongue of steel, which will only

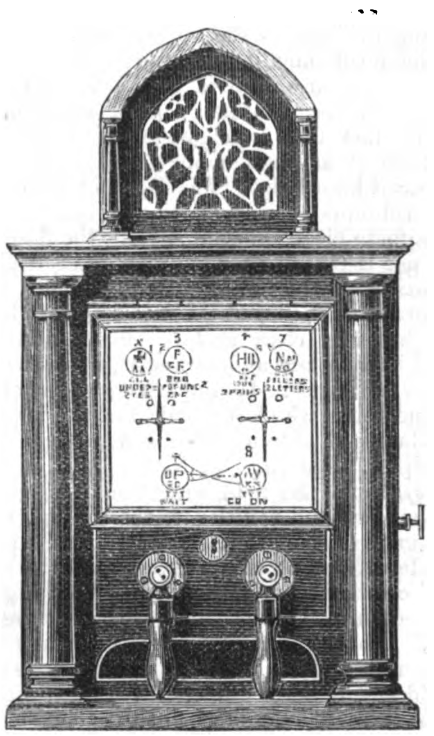

FIG. 5.—Original Two-Needle Instrument.

cease to discourse with the extinction of man himself. Mr. Cooke, in his turn, touched the keys and returned the answer. 'Never did I feel such a tumultuous sensation before,' said the professor, 'as when, all alone in the still room, I heard the needles click ; and, as I spelt the words, felt all the magnitude of the invention, now proved to be practical, beyond cavil or dispute.' Mr. Fothergill Cooke has earned for himself the right to claim the honour of being entitled to stand alone as the gentleman to whom this country is indebted for having practically introduced and carried out the electric telegraph as a useful undertaking."

Next to a four-needle instrument is exhibited the identical "double needles" which led to the capture of John Tawell, the Quaker murderer, on January 1st, 1845. These instruments worked between Paddington and Slough.

The general public had apparently regarded the electric telegraph as a mere novelty until, by its means, a man who had committed a terrible crime was brought to the gallows; and the telegraph was then recognised as an invaluable agent of communication. The messages despatched on that occasion are engraved on brass plates secured to the base of the

Digitized by Google

instruments. The inscription on the Paddington instrument is:—

"On January 1st, 1845, the following message was received by this instrument at the Paddington Station:—

'A murder has just been committed at Salt Hill, and the suspected murderer was seen to take a first-class ticket for London by the train which left Slough at 7h. 42m. p.m. He is in the garb of a Quaker, with a brown great coat on, which reaches nearly down to his feet; he is in the last compartment of the second first-class carriage.'

"On January 1st, 1845, the following reply was sent by this instrument from the Paddington Station:—

'The up train has just arrived, and a person answering in every respect the description given by telegraph came out of the compartment mentioned. Pointed the man out to Sergeant Williams. The man got into a New-road omnibus, and Sergeant Williams into the same.'"

Fig. 5 is a drawing of the Paddington instrument. That at Slough was similar.

(TO BE CONTINUED.)

MAGNETO-ELECTRIC MACHINES.

A striking evidence of the interest which is taken by the public in the developments and progress of electrical science, or else of the attention called to the subject by the recent excited speculations in electric light companies, is to be found in the fact that some, at least, of the daily papers begin to treat it as though they realised the fact that it requires special knowledge. *The Times* of 13th June devotes over three columns to a description of some of the leading types of magneto-electric machines, and the description gives clear evidence that its writer knows a great deal of the subject he treats of.

The general description of the principles of electrical generating machines is clear and excellent, and though the general public will not understand it, some leaven of information will, no doubt, be imparted; while the partially-informed and those who have looked at the machines at the Crystal Palace will obtain a fair general comprehension of their principles, especially as to the relations of the two magnetic systems, the field and the armature; also the different purposes and utilities of the continuous and alternating current systems are fairly stated and explained.

The readers, however, require to season the article with a "gramme" or two of salt. It is already very highly seasoned in one direction—it bears an overwhelming flavour of "Gramme." Now, the Gramme machine is an admirable one, and its inventor and its introducers have done a great work in the world and deserve due credit. The principles of the Gramme have served as a ferment to excite further growth, and the scientific mind must recognise that the greater part of the new "systems" so much talked of lately are simply modifications more or less (generally less) important of the Gramme machine. But it is too much to claim that all machines are mere Grammes. That is what those interested in the Gramme are doing, and that claim is even assuming a legal form, and this is what *The Times* article would make people believe. But can any disinterested scientific man uphold such distinct statements as this:—"The Brush machine has a Gramme ring;" or this other as to De Meritens's machine, "It has five Gramme rings." It is, of course, probable that the Gramme ring, or more correctly the Pacinotti ring, did furnish a suggestion in both cases, but as a scientific fact neither the Brush nor the De Meritens ring armatures have any relationship to the Gramme.

Some time ago there arose a partial discussion as to what the essential feature of the Gramme machine is. We were informed by Mr. Werdermann that there was a fundamental distinction between the Pacinotti ring and the Gramme ring, and that any one could use the Pacinotti unquestioned by those concerned in the Gramme patents. The distinction then stated was one as to which the writer possessed some personal knowledge; however, it was this, that the Pacinotti ring was a solid one, and the Gramme ring was composed of coiled up wire. Now, adopting this distinction, the Brush ring may be, in fact clearly is, an improved Pacinotti ring as to its core, and as clearly it is *not* a Gramme ring, and as to its coils of wire it is neither a Pacinotti nor a Gramme ring, but one based upon entirely different electrical principles.

As to the De Meritens, it no doubt arose in the mind of the inventor from considering the Alliance and Gramme machines. But though the form is a ring *apparently*, and it therefore might be fathered by the Gramme, its true scientific parentage has nothing to do with the Gramme. It is in scientific truth *not a ring at all*, but a series of independent electro-magnets. The ring form is a mechanical matter. It is very evident that if we mount a number of radial electro-magnets upon a revolving shaft, acted upon by surrounding N and S magnetic poles, this is in no sense a Gramme ring. Now, De Meritens's ring is simply that identical thing with the middles of the horseshoes disconnected from the shaft, then straightened out and formed into a circle in which the separate ends are brought together and the arrangement of the wires suited to the consequent polar order set up by the action of the external magnets.

In like manner, though the distinction between the Gramme and Siemens armature is fairly stated, it is remarked "that all that we have said of the iron ring in the Gramme machine is equally applicable to this machine," and the wording of the description of the commutator would certainly lead ordinary readers to suppose that it and its action are "precisely as in the Gramme machine." But the fact is that, though there are resemblances, the action of the ring is very different, and the commutator is based upon wholly different principles, as also it is in the Brush.

The Bürgin machine is fairly described with a strong dash of this prevailing flavour, and then after the description of all the machines a distinct paragraph is devoted to the remark, "All these machines employ the Gramme ring." A scientific critic, as distinguished from an engineering one, might object to the statement that "the most peculiar modification of the Siemens armature is that which has been introduced by Mr. Edison." He might possibly enquire what the modification is beyond some mechanical engineering matters of details of construction.

While the description of the machines is marked by accuracy, qualified by the prevailing tone of mind, there is one serious misstatement of fact. In describing their actions as electromotors it is said, "If the current supplied to the machine is in the same direction as that which the machine would produce in working forwards, the machine will be driven backwards. To drive it forwards we must supply it with a current opposite to that which its forward motion would produce." This is true only when the field magnets are permanent ones. The statement is incorrect as to machines with electro magnetic field systems. In these the motion will be in the same direction, whatever the direction of the current. In fact, the field magnets assume polarity according to the direction of the current, and so does the armature, but these being always opposite, whatever the current, the direction of motion is controlled by the arrangement of the brushes of the commutator, and the mutual reactions of the two magnetic systems. In fact, a ring armature may be considered as representing at any moment a bar magnet suspended between the poles of a horseshoe magnet, whose attractions compel it to move in one direction. Now, if we reverse the polarities of both bar and horseshoe, it is evident we leave the direction of the attractions, and the consequent motion, unaffected. If we wish to obtain reverse motion we must reverse only one of the magnetic systems (of course the ring) as is the case where permanent magnets form the field.

THE EDISON LAMPS IN BRAZIL.—The *Rio News*, of Rio de Janeiro, Brazil, says that the experiments with the Edison electric light at the Dom Pedro II. Station in that city are resulting very satisfactorily. The electricity is supplied by a Gramme machine.

THE TELEPHONE CASE.

(CONCLUDED FROM PAGE 82.)

Professor SILVANUS THOMPSON when recalled gave the following answers to the questions asked :—

Q. Will good conductors make a tension regulator ?—A. Yes.

Q. How ?—A. You only want two good conductors brought into contact lightly, so that there is what one may call light contact between them, and exposed to vibrations of the voice, and you will have a perfect tension regulator, simply because the resistance of two perfect conductors in contact with one another may be made to vary from a resistance which is very great indeed down to a resistance of a small fraction of an ohm. I can quote Sir William Thomson's words he uttered in this box.

Mr. Justice FRY : I suppose practically you agree with the view presented, that it is more convenient to have a substance of low conductivity than of high ?—A. Not necessarily in itself.

Q. I said practically.—A. No ; in the Hunnings transmitter we try to get the best conducting carbon we can, the oven-made engine-coke.

Q. You would not put silver to it ?—A. For quite other reasons.

Q. Would you say practically it is convenient to have a high conducting substance ?—A. I prefer a high conducting substance, others being the same. If you wish to know the reason why everybody pefers some form of carbon for tension regulators, it is not because carbon is a semi-conductor, it is simply because carbon does not melt at the point where the current is running through the contact, for the very same reason that plumbago was used in the relay that the points should not stick, and for that very same reason I believe it to be, carbon is found in one form or other to be the best working substance in the tension regulator ; and once get a substance which, like carbon, does not fuse at the point of contact, then for the Hunnings transmitter give us the best conductor possible, and the best conducting kind of carbon is the one that suits us best.

Q. That is, after all, but a poor conductor ?—A. It is not so very far behind platinum—it is many millions of times better than the lampblack. I have here two specimens of carbon, one in a tube, and the other a rod. This is a rod of coke, artificial gas coke, used for producing the electric light. This is a tube, the internal dimensions and length being, as near as possible, the same, filled with what we call the best quality of lampblack, bought at an ordinary shop. I measured the resistance of this myself. I have had this measured—for the resistance of it was far too high for any appliance I had at Bristol—at Muirhead's, and this resists the passage of electricity about 160 million times as much as this piece of carbon. I would not like to take a shock from a large Leyden jar by this rod because it would knock me down. I should not object to approach any electrical machine with this rod of lampblack, because lampblack is practically a non-conductor. I may make the illustration a little more perfect. Suppose I were working one of those little incandescent Swan lamps, and I were to interpose in the path of the current this rod of carbon, it would go through, and you would not see a perceptible difference in the brilliancy of the light, but to get enough current to make a Swan lamp work through with this, you would have to take one of the largest dynanomical machines at the Crystal Palace—to take about 2,000 of those machines, and set them one after another to drive a current through, so enormous is the resistance of this tube of lampblack. I should be correct in saying more electricity will creep along the moisture of the glass outside than will slip through the carbon inside. Lampblack is practically a non-conductor for all electrical purposes.

Mr. PEARSON : Could you work lampblack in the Hunnings instrument with batteries of the same power which you work Hunnings's instruments with for practical purposes ?—A. Certainly not.

Q. Can you give me at all the difference of power you would require, if even any amount of power would enable you to work it ?—A. I could not get in Hunnings's transmitter what I consider any practical result at all even with an enormous power—with a very great battery power, that I might test the thing fairly.

Dr. ALEXANDER MUIRHEAD stated that he knew the number of the "Zeitschrift" containing the paper by Legat on the reproduction of sound ; that he saw the volume about the middle of 1876 in the Patent Office Library.

Mr. LADD, who described the Reis instrument at the British Association at Newcastle in 1863, testified to the following description of the instrument :—

"This instrument consists essentially of two distinct pieces of apparatus. That for transmitting the signal has a small mouthpiece. On the right-hand side there is a finger-key forming part of the circuit, and an electro-magnet with a vibrating armature and binding screw to connect with one of the line wires. Within a case under a glass cover is an elastic membrane, in the centre of which is fixed a platinum plate in connection with the finger-key. A light angular piece of metal resting on three pins is so placed that the pin at the angle rests on the plate in the centre of the membrane ; " that is, at the apex of the triangle ?

Q. "The other two resting in cups on its edge, so as to allow of free motion on the points. In the body of the receiver-box is suspended a soft iron core, surrounded by a coil of silk-covered wire, one end of which is in connection with the finger-key, and the other with the binding-screw. The method of producing sound in the receiving instrument depends upon the fact that at the moment of magnetising or demagnetising a piece of iron there is an alteration in the arrangement of the particles, which gives rise to a slight ticking noise. Having connected the transmitter by means of an insulated wire with the receiver, and the binding-screws having been brought in connection with the battery of three or four elements, if the finger-key on the transmitter be pressed, the person at the receiving-station hears the ticking noise. To convey a musical note or sound, the operator places his mouth to the tube in front of the instrument and sings a note, when immediately the membrane begins vibrating in accordance with the note sounded, and at each vibration breaks contact between the pin and plate in its centre." That is a proper description ?—A. Yes, it is.

Q. "This forming part of the circuit causes the iron core in the receiving instruments to be magnetised and demagnetised a number of times equal to the number of vibrations of the membrane, and so conveys to the receiver an impression of a musical sound. The finger keys and small magnet at the sides of the instruments are for the purpose of varying the methods of communication by the combination of single sounds, and can also be used with the other parts for the purpose of regulating the lengths of the notes and dividing them into varying portions, so as to form a sound alphabet somewhat similar to the signals written by Morse's telegraph." That is a proper description ?—A. Yes.

After Professor Dolbear, Mr. M. W. Dunscombe, Dr. Stone and others had been examined came the examination of Professor W. E. BARRETT, which contains information on quite a number of experiments. He showed that a Morse sounder would speak loudly and plainly; that the Glasgow instrument would speak with any metal across it, such as a saw or a knife, which was tried. In reply to the question whether he had written about the Reis instrument, Professor Barrett said :—I have written a great many papers from time to time on the Reis instrument. I have taken the general view of scientific men at the time, the popular view, that it was a make and break instrument. As such it was generally regarded until the experiments were made first of all by Mr. Yeates in Dublin, and attention was turned to the fact that broken snatches of words could be transmitted, and this I confirmed by frequent experiments, and found subsequently that Reis mentioned exactly the same thing. I have not thought it necessary to modify the view that I held as to the mere make and break in the Reis, and although, popularly speaking, if you speak loudly into it it is make and break, I find, if you speak very gently, there would be no make and break. The discovery made by Mr. Edison, and, indeed, I may say, the discoveries made by Bell and Gray, would all of them, taken together, lead me to modify my views of the Reis, and in a paper published some time ago I stated when speaking gently the Reis undoubtedly acts according to the same principle as the tension-regulator in Edison's patent.

Mr. Justice FRY : When was that announcement made by you ?—A. Comparatively recently; it is reprinted in the *Electrician* last week, I believe.

Q. Is your conclusion made this year ?—A. Oh, no, about three years ago, since the discovery of Edison, since they were both made known. Since I became acquainted with Edison's carbon telephone I went back to Reis, and found in that telephone an explanation of the words which I heard which always puzzled me, although I had a clear information in my paper of the make and break instrument. I do not read German, and I had Reis's paper translated, and he mentions the transmission of speech, and how the speech could only be transmitted. It is rather technical, but I may be allowed to explain it. A musical note varies only in the pitch, in length of the wave, or in the amplitude of the wave. A make and break instrument can only transmit the speech—the varying length of wave ; but the quality of the voice in speaking, or a compound tone, can only be transmitted by the closed circuit, inasmuch as it depends on the form of the wave, not the amplitude or the length of the wave, but the peculiar form. The particles there are oscillating in one direction and back again ; and Reis does transmit the form of the wave, and I find the inventor of the instrument had even mentioned this in his paper that compound tones could be transmitted ; he recognises the scientific principle of the instrument

Digitized by Google

very much more clearly, I think, than people did in England afterwards.

Prof. Barrett in his evidence concerning tension-regulators said that he had heard a couple of sixpences speak beautifully in the plate transmitter, taking out the carbon buttons and putting in the silver, also with a button of silver highly polished, also with nickel. Carbon is used, however, because metals fuse at the points of contact. He also described an experiment with coke particles sprinkled on a gridiron, and a wire electrode embedded in putty thus:—"This is an experiment with the object of ascertaining whether speech could be transmitted without anything resembling a tympan—even using the word in the most liberal sense. I bedded in putty a series of copper wires, and by the side of them another set of copper wires, making them together into a gridiron, fastening the whole firmly down, and sprinkling on the top some of this Hunnings powdered gas coke. I then spoke to this arrangement, and an assistant in a different room listened and told me heard. Then we changed places, and I heard him, so that speech could be transmitted with perfect distinctness by this arrangement. I may add that I supported the base of this on three little knobs of putty to insulate it as far as possible from the table on which the whole thing rested."

Another experiment was thus described:—"I had the following arrangement made. It is a ring of brass very like the electrode on the putty, mounted in an ebonite case, and a sheet of horn placed in front, and another sheet of horn placed behind between the two which are one-quarter or one-eighth of an inch thick. The coke is placed, and speaking on this the speech was transmitted with marvellous fidelity and loudness. Here the electrodes are at right angles to the direction of the sound of the waves, at right angles to the ordinary direction. Then pinching the horn on each side with the fingers so as to stop any tympanic action possible, still speech was transmitted. Putting two little cocks in the centre of each horn-electrode, and screwing it up tightly in a vice and then speaking to it, still speech was transmitted, only more faintly—the particles were then being squeezed too tightly together. Then I removed the horn and placed muslin, everything else being exactly the same. With this arrangement the most admirable transmission of speech was obtained. I do not know that anyone can wish for a better transmitter than a pair of muslin surfaces with gas coke between an electrode and solid plates of glass bedded in the ebonite case. . . . . As it might be urged, possibly, that some tympanic action reached the electrodes through the ebonite case, I removed the semi-circular piece of brass, and hung down two strips of this platinum foil attached to the one end only. Here is the one strip attached to the one binding screw, and the other strip attached to the other binding screw, fixed only at one end, and speaking into this also the most beautiful transmission of speech was obtained, the electrodes in no sense being attached to the horn-sheathing here, quite free as you can see, shaping about. Perhaps the most beautiful that I have ever obtained was by using gelatine sides arranged in the same way as the horn."

An experiment with apparatus as in Edison's patent was thus tried:—"I took an ordinary Edison carbon transmitter, and adjusted the buttons to get good speaking. I then removed the buttons, after testing the perfection of the instrument, and put two circular electrodes round the button, precisely analogous to the gelatine transmitter. I then again put the parts of the instrument together exactly as they were before, only leaving out the electrodes that Edison put in. With this arrangement no speaking can be heard, however careful the adjustment may be."

The conclusion of Professor Barrett is, "That in using the Edison carbon transmitter you must have a tympan and screw adjustment, and an electrode above and below the button to work well; if you alter any one of those parts you spoil the working. If you move the tympan and have only the electrode above and below you have no means of adjustment, and consequently it cannot speak well. If you leave the tympan and move the electrodes, passing them round the button in this form, and then adjust them as before, you will have no speaking, simply because you have not the means of adjustment. There is no possibility of talking through this carbon. There is a carbon telephone in all respects the same as Edison's, only with electrodes hopelessly bad."

Professor W. E. Ayrton in his evidence gave the results of experiments on resistances, which are interesting.

Q. Tell us the results of the resistances of the different substances on which you experimented.—A. There are many substances, therefore I will only take a few. I have taken Hunnings's coke in a solid state, powdered, with definite pressure. The moment you deal with powders, and speak of their resistance, it is necessary to specify—if the result is to have any scientific value —what pressure per square inch is exercised on the powder during the experiment; therefore, in these results the pressure per square inch has been specified. The results are compared with silver and copper, the resistance of which, of course, is well known.

Q. What does silver come out on the standard you are using for your comparison?—A. I put down silver as 1·6, that being a resistance of a cubic centimetre, the size I was adopting for my experiments.

Q. What is the resistance of Hunnings's coke in this solid form on the same scale?—A. About 80,000.

Q. This is resistance, not conductivity?—A. It has to be remembered the substance is very porous; indeed, when you speak of an absolute cubic centimetre of this as an internal volume, it has really not got so much volume, because there are many holes. If the substance were in a more compressed state, solid and fewer holes, the resistance would be less. When you talk of a cubic centimetre of silver, you mean solid silver, not spongy; whereas, you deal here with a substance filled with holes of a considerable size.

Q. Did you try Hunnings's coke in a powdered state?—A. Yes; under various pressures, and under pressure of 14lb. to the square inch it is about 246,000.

Q. Fine powder, or powder such as Hunnings uses in his transmitter?—A. It was a finer powder than Hunnings used in his transmitter; and, therefore, the resistance under the same pressure undoubtedly is considerably more than one would have obtained if he took the powder that he uses. I wished to get the two classes of gas coke from the solid block, and as fine powder as a pestle and mortar could reduce it to.

Q. Can you draw any inference from those two experiments as to the limits within which the resistance of Hunnings's coke, as he uses it, must be taken?—A. I think the resistance might be taken as between solid and extremely fine powder.

Q. It would be between the two?—A. Yes, I believe so.

Q. The resistance of Hunnings's coke, as he uses it, would be between 80,000 and 240,000?—A. Yes.

Q. Did you try Edison's in the solid state?—A. Yes.

Q. What did that come out?—A. In the solid state it comes out about 558,000; that is about twice the resistance of Hunnings's coke powdered.

Q. Now, did you try Edison's button powdered?—A. I have also tried that powdered, that is, about one hundred and twenty-two millions, with a pressure of 7¾lb. per square inch.

Q. Did you try any specimen of lampblack?—A. I have tried several specimens of lampblack.

Q. Tell us where you got them, and what the results were.—A. Some specimens were got from Burgoyne and Burbage, well-known chemists, and I have also experimented on the same specimen of lampblack that Professor Barrett used, bought in London, because it was very desirable we should know the real resistance of the specimens he bought in the way he described to you. He bought some at 68, Farringdon-street, and elsewhere. I have tried all the specimens Professor Barrett sent me.

Q. Can you identify those?—A. I have tried superior lampblack, No. 4.

Q. Give us the superior lampblack.—A. Superior lampblack, No. 4, under a pressure of 14lb. per square inch, is 542 million millions. That is about two million times the resistance of powdered Hunnings coke. Where we are dealing with substances like gutta percha and india rubber, we are accustomed to many millions of millions of resistance.

Mr. Justice Fry: Why is it you have subjected the different materials to different modes of pressure?—A. Of many of them I have taken a set of pressures. For example, the lampblack I now refer to, the superior lampblack, I have tried altering the pressure from 4lbs. per square inch to 14lbs. per square inch. I am only here giving the results of one or two of the experiments made with each substance. In reality, I made a more or less complete experiment with each substance; for instance, the lampblack No. 4 diminished its resistance only from 8 to 5—that is, from 800 million millions to 500 million millions—and the pressure was increased from about 4lbs. to 14lbs. per square inch. On the other hand, I found Hunnings's coke in a finely powdered condition diminished its resistance from 80,000, the original resistance, to 20,000 when the pressure was only increased from 8 to 14—that is to say, not only did I find the Hunnings coke has a resistance of about a two thousand millionth part of the resistance of this lampblack, but I found under a less variation of pressure a far greater change in the resistance, Hunnings's coke varying from 80,000 to 20,000, that is, reduced to about one-fourth when the pressure was changed from 8 to 14lbs.

Mr. Hemming: To take another specimen, the Burgoyne and Burbage sample you got yourself, did you get a result as to the resistance?—A. The resistance of that was 191,000 millions compared with silver at 8¾lb. per square inch, and 174,000 millions under a pressure of 15.

Q. Roughly, about a million times; something like a million times the Hunnings coke?—A. About a million times.

Digitized by Google

Q. The other lampblack was 2,000 million times the resistance?—A. The resistance of powdered Hunnings coke.

Q. Among all the specimens you tried, are these the highest and lowest, these two you mentioned—the Burgoyne and Burbage at 191,000 millions, and the superior lampblack?—A. I tried another specimen. I tried best lampblack, bought at 68, Farringdon-street.

Q. Was that lower or higher?—A. Higher.

Q. Is this 191,000 millions the lowest?—A. The lowest lampblack I have come across.

Q. In the other, 543 million millions was the highest?—A. Not the highest.

Q. Have you one higher?—A. The best lampblack, bought at 78, Farringdon-street, had a million million times 1,150,000. The figures are so large that one is liable to get into confusion. It is 1,150,000 million times the resistance of silver, 1,150 million million times.

Q. That I make about upwards of 4,000 million times the resistance of Hunnings coke?—A. Taking the powdered coke of course.

Q. It is something intermediate between the two. You made many other experiments on other substances?—A. I made many other experiments on other substances.

Q. Which you will be happy to give my friends if they want. Just tell me this, because there is a difference of opinion about it, whereabouts does platinum come?—A. Platinum is about six times the resistance of silver.

Q. What is the number?—A. 9·2.

Q. What is iron?—A. About 9·8. I made an experiment which was interesting on amorphous phosphorous, I took that because it was mentioned by Edison. I bought that from Hopkins and Williams, the distinguished chemists, and I found it to be a million million times the resistance of silver.

Q. You know what the Hunnings transmitter is, and you know what the Edison transmitter is? In your judgment does Hunnings's transmitter contain a combination of a tympan or diaphragm with a tension regulator.—A. No, certainly not. I consider that the tympanum is essentially absent from the Hunnings transmitter. I do not consider the platinum foil at all takes the place of an acoustic tympanum.

Q. Have you any experience of the use of substances of different degrees of conductivity in the transmitter—have you compared the action of substances of different degrees of conductivity in the transmitter?—A. I have listened to receivers when various transmitters have been employed.

Q. What is the substance of highest conductivity you have tried—have you tried any of the metals?—A. I have heard, I cannot say I have tried, because I did not make the experiments. I have seen experiments made by others, and I have heard two pieces of silver used in the transmitter, and I certainly understood the words spoken—given out by the receiver. That is the substance of the highest conductivity and lowest resistance.

Mr. H. S. Eaton, librarian of the Institute of Civil Engineers, and Dr. Hopkinson, gave further evidence, when the case, so far as evidence is concerned, concluded, the result being as given in the decision of Mr. Justice Fry, which has been fully printed in a previous number.

PHYSICAL SOCIETY.—June 10.

Professor Clifton, President, in the Chair.

Mr. W. F. Stanley read a paper on "Sonorous Vibrations," especially those of the tuning fork. The larger and more visible movements of a sounding body do not appear to be best fitted to propagate musical sounds, as was shown by placing discs on the prongs of a powerful fork, which, when vibrating, could then only be heard a short distance; whereas, by its smaller longitudinal motions when placed on its resonator it produced a penetrating sound. The vibration down the stem of the fork was shown not to depend upon a vibrating ventroid as suggested by Chladni, for a fork cut in the end of a solid steel bar communicated sonorous vibrations equally well to the resonator. To set a fork in vibration it was necessary to bow one prong only, therefore in this case the vibration must proceed along the prongs. A light fork one metre long was fixed in a heavy vice, and it was shown by it that vibrations passed down one prong and up the other alternately. By means of dust ripples were shown to run down an ordinary fork in vibration. Light pieces of metal were fitted to the ends of a powerful fork, and these immersed in mercury, the reflected surface of which was shown on a screen, where it was seen that the whole mercury surface was broken into fine ripples. It was suggested that such small waves are also perceived by the ear. By these certain conditions of harmonies could be better accounted for, as, for example, by division in smaller waves the rarefaction of a note in space would not suffer interference by the condensation of the octave falling in the same space and time.

Lord Rayleigh explained several of Mr. Stanley's experiments on the known theory of sound.

Mr. Walter Baily then exhibited a model of a new "integrating anemometer." This apparatus contains a horizontal plane, in which are two slits forming a cross with arms towards the cardinal points. Each slit is fitted with a sliding piece, and the two slides are connected by a bar, the arrangement being that of the well-known instrument for drawing ellipses. The slides carry beneath them wheels with their planes perpendicular to the slits, and passing through the pivots of the bar. The wheels rest on a horizontal disc whose centre is beneath the centre of the cross. The centre of the bar is to be connected to a weathercock which will keep it in the direction of the wind when looked at from the centre of the instrument. The disc is to be revolved by Robinson's cups. The number of revolutions of the wheels then give the integral of the resolved parts of the wind in the direction of the cardinal points. In the working model of the instrument exhibited there was an electrical arrangement connected with four indicators, one for each of the cardinal points. At each turn of a wheel a current was completed, and the corresponding indicator moved. The cording instruments are to be substituted for indicators, and the amount recorded on each in a given time will be proportional to the total motion of the wind towards the corresponding cardinal point.

Mr. Lecky pointed out that a good anemometer was a great desideratum at present.

The society meets at Oxford on the 17th, and South Kensington on the 24th of this month.

GREAT WESTERN ELECTRIC LIGHT AND POWER COMPANY.

An extraordinary meeting of the shareholders of this Company was held on Wednesday at the Cannon-street Hotel. Mr. H. B. Evans in the chair.

The Chairman explained that the meeting had been called for the purpose of confirming the resolutions passed at the meeting of the Company held on the 30th of May last. The resolutions referred to had reference to the Articles of Association of the Company, and they were asked to pass them in compliance with the Stock Exchange regulations before they would be granted a settlement and quotations. The resolutions were carried, and the proceedings closed.

The first general meeting of the Company was then held, Mr. Evans again presiding.

The Chairman said they had not allotted many shares up to the present. They had sold the concession of Devon and Cornwall for the sum of £15,000. Negotiations were pending with regard to the opening of a central station at Bristol. They had absolutely secured a central station at Cardiff, where operations will at once be commenced. There was also promise at Newport. He believed they would soon be doing a considerable business in other towns. The future prospects of the Company were of a most favourable character, and he had no doubt that the electric light would be the illuminator of the future.—The proceedings then terminated.

PROSPECTUS.

This Company is formed for the purpose of manufacturing, working and supplying in Austria, Hungary and Roumania, apparatus for the application of electricity, and of promoting local companies or associations for working the same.

The Company has contracted with M. de Kierzkowski-Steuart for the purchase of the following patents and advantages, viz.:—

(a) All the patents of the Anglo-American Brush Electric Light Corporation (Limited), for the Austrian Empire and for the Kingdom of Hungary, for the inventions of Charles Francis Brush and St. George Lane-Fox, which patents are seven in number, and are respectively dated and numbered as follows:—

17th Oct., 1880.	No. 26940.
Do. do.	No. 28093.
11th Nov., 1881.	No. 25919.
17th Nov., 1881.	No. 32090.
Do. do.	No. 32091.
18th Nov., 1881.	No. 27605.
29th Jan., 1882.	No. 40625.

(b) All improvements in the above-mentioned inventions to which the Anglo-American Brush Electric Light Corporation (Limited) may be entitled under their now existing agreements with Charles Francis Brush and St. George Lane-Fox respectively.

(c) The engagement of the Anglo-American Brush Electric Light Corporation not to sell, make, or use in Roumania any of the inventions the subject of the respective patents so long as the same or any extension thereof remain in force.

It is needless to dwell on the merits and commercial value of the "Brush" patents, which have been amply proved by the extraordinary financial success of the Brush Electric Company of Cleveland, Ohio, U.S. (now of several years standing), and of the Anglo-American Brush Electric Light Corporation (Limited) of London.

The Lane-Fox patents comprise the well-known system of lighting by incandescence and a new and complete system of distribution, utilising the principle of storage.

The Company will thus be enabled to undertake for all purposes indoor and outdoor lighting.

The price of gas is known to be much higher in Austria than in England. Thus the Company may look for great advantage in respect of competition with gas.

The Anglo-Austrian Brush Electrical Company will possess, not mere licences, but the absolute property of the "Brush" patents for Austria-Hungary, and will be in a position to achieve in those countries what the Companies above referred to have done in the United States and in England.

The field of operations in respect of which rights have been secured is of vast extent. The Austro-Hungarian Empire has an area of 250,000 square miles, and a population of over 37¾ millions. Amongst the principal cities and towns are Vienna with 1,028,000 inhabitants, Budapest 271,000, Prague 190,000, Trieste 109,000, Lemberg 87,000, Gratz 82,000, Brünn 74,000, Presburg 47,000, and a very large number of smaller towns with populations of 40,000 and less.

As regards Roumania, the Anglo-American Brush Electric Light Corporation is precluded by the agreement with the Vendor from carrying on its business there. The population of the Kingdom of Roumania is over 5,073,000; and amongst the principal towns are Bucarest with 222,000 inhabitants; Jassy with 90,000; Galatz with 80,700.

It is proposed to take immediate steps for the formation or promotion of local Companies for the purchase and working of licences for the lighting of the above-mentioned and other towns and districts, and for the introduction of other applications of electricty. It is also intended forthwith to erect works or make other arrangements for the manufacture in the Austrian Empire of the electrical apparatus which will be required by the subsidiary Companies and by the public

These measures will be in accordance with the policy so successfully pursued by the American and the English parent Companies.

It is important to note that the Company will by these arrangements remain in possession of the business of manufacture (a business which in other countries has proved highly lucrative) after creating by the sale of licences a large market for the apparatus manufactured. Some notion of the probable profits of the Company may be formed from the last published balance sheet of the Anglo-American Brush Electric Light Corporation (Limited), which on a paid-up Capital of £238,006 showed a profit for the first year of £134,965 6s. 1d., out of which the whole of the expenses of formation of the Company were paid, and a dividend of 12½ per cent. was declared; 10 per cent. was written off for depreciation of plant and machinery; £99,500 was carried to reserve fund, and the balance of £2,934 18s. 9d. was carried forward.

The agreement with the Vendor provides that pending arrangements being made to manufacture in Austria the Anglo-American Brush Electric Light Corporation are to supply the patented apparatus at a discount of 20 per cent. on their tariff prices.

The Vendor has procured the first subscription of 12,000 shares of the Company. 8,000 shares are taken by him in part payment of the consideration money, as hereinafter appears. The remainder (being two-thirds of the present issue), viz., 40,000 shares, are offered to the public.

The Vendor has undertaken to pay all expenses attending the formation of the Company, up to the allotment of shares, excluding only brokers' fees.

As consideration for the transfer to the Company of the patents above referred to, and the benefit of his agreement with the Anglo-American Brush Electric Light Corporation, and for his services in the formation of the Company, and the subscription of the Capital, the Vendor is to receive £55,000 in cash and 8,000 ordinary shares, with £2 10s. per share credited as paid up thereon.

The only contract entered into by the Company is dated 12th June, 1882, and is made between C. de Kierzkowski-Steuart of the one part, and the Anglo-Austrian Brush Electrical Company (Limited) of the other part.

The contract entered into by C. de Kierzkowski-Steuart with the Anglo-American Brush Electric Light Corporation (Limited) is dated 31st May, 1882. It states that on the 13th day of May, 1882, the said C. de Kierzkowski-Steuart paid to the Anglo-American Brush Electric Light Corporation (Limited) the sum of £11,000 by way of deposit, and in part payment of the sum of £44,000, being the price agreed to be paid by him on or before the 22nd of July, 1882, for the patents and other rights now agreed to be transferred to this Company, and that in default thereof such payment of £11,000 should be absolutely forfeited.

The Articles of Association provide that Mr. C. de Kierzkowski-Steuart, being interested as a vendor to the Company, and Mr. St. George Lane-Fox, having an interest with the Anglo-American Brush Electric Light Corporation in the patents sold, although respectively directors of this Company, shall not vote or take part in any matters relating to the carrying out or modification of the said agreement.

Copies of all the above-named Agreements and of the Memorandum and Articles of Association of the Anglo-Austrian Brush Electrical Company can be inspected at the offices of the Solicitors.

In the event of no allotment being made the deposit on application for shares will be returned in full.

Copies of the prospectus may be obtained on application to the London Bankers, Brokers, Solicitors, or Secretary of the Company.

Applications for Shares must be made on the form accompanying the Prospectus, and must be forwarded to the London Bankers, together with the amount payable on application.

Immediately after allotment a Stock Exchange settlement and quotation will be applied for.

No.

FORM OF APPLICATION FOR SHARES.

TO THE DIRECTORS OF THE

ANGLO-AUSTRIAN BRUSH ELECTRICAL COMPANY (LIMITED).

GENTLEMEN: Having paid to your Bankers the sum of £ , being a deposit of 10s. per Share, I request you to allot me Shares of £5 each in the Company, and I agree to accept such Shares, or any less number that may be allotted to me, upon the terms of the Prospectus, and subject to the Memorandum and Articles of Association of the Company, and I authorise you to place my name on the Register of Members in respect of the Shares allotted to me.

TEMPORARY OFFICES.
No. 6, LOMBARD STREET, London, E.C.

PROSPECTUS.

This Company has been formed for the purpose of acquiring and using in the Empire of India, Ceylon, Australasia, and South Africa the rights and privileges of Mr. Thomas Alva Edison relating to the application of Electricity or Magnetism as a lighting, heating, or motive agent (except the application thereof for the purpose only of locomotion on railways or tramways or common roads, and except also the right of the Cape Government to use an installation which has been already sent out to them), and for the other objects specified in the Memorandum of Association, a print of which is issued with the Prospectus.

A large number of Patents or Letters of Registration have been obtained by Mr. Edison for India and the Colonies of Victoria, New South Wales, Queensland, and New Zealand, all of which are secured to the Company. Applications for Patents or Registrations have been or will be made in the last-named Colonies, and in South Australia, Tasmania, West Australia, South Africa, and Ceylon, which when obtained will belong to the Company, without any further payment except the cost of making or completing such applications.

In addition to the above, the Company has acquired a most important advantage in the right to patent and use in Australasia, South Africa, India, and Ceylon, all Mr. Edison's improvements which may be made during the term of five years, from the 12th day of June, 1882. No further payment will accrue to Mr. Edison on the Company exercising this right. After the expiration of the term of five years the Company will have the option of acquiring all additions and improvements made and patented by Mr. Edison on payment of such sums as may from time to time be agreed on or fixed by arbitration in case of difference. The only reservation in favour of Mr. Edison is in respect of locomotion on railways, tramways, or roads.

The Edison Incandescent Lamp is unequalled for domestic and general illumination, and is suitable for all places where a steady, brilliant light, obsolutely safe in its production and use, is required. It is peculiarly adapted for India and other tropical countries, as it will be unaffected by Punkahs and wind currents, and emits comparatively little heat. When once fixed it requires no skilled labour, but can be attended to by an ordinary native or other servant.

The Edison System, however, does not merely comprise a particular form of lamp, dynamo or regulator, but is a comprehensive whole, embracing every detail essential to the economical, reliable, and safe production and distribution of Electricity for the innumerable purposes to which it can be applied, whether in connection with light, heat, or motive power. It includes many ingenious and effective devices believed to be peculiar to this system, some of which are referred to in the following extract from a lecture at the Society of Arts, by Mr. W. H. Preece, F.R.S., Electrician to the Post Office, which affords important independent testimony to the above statements.

"The completeness of Mr. Edison's exhibit was certainly the most noteworthy object in the (Paris) Exhibition. Nothing seems to have been forgotten, no detail missed. There we saw not only the boilers, engine, and dynamo-machine, but the pipes to contain the conductors; the conductors themselves, heavy and massive—for Mr. Edison recognises the waste of energy that must occur in small conductors—the insulation, the fixtures, the brackets, the safety catches, the lamps, devices to avoid the effects of expansion and contraction through changes of temperature, meters to measure the current used, regulators to control the consumption of fuel." . . . "Mr. Edison's system has been worked out in detail, with a thoroughness and mastery of the subject that can extract nothing but eulogy from his bitterest opponets. Many unkind things have been said of Mr. Edison and his promises; perhaps no one has been severer in this direction than myself. It is some gratification for me to be able to announce my belief that he has at last solved the problem that he set himself to solve, and to be able to describe to the Society the way in which he has solved it."

The Safety-catch, above referred to, is an invention for preventing danger from fire in case of the conductors generating heat by reason of breakage or other accidental injury.

The system may be seen in full operation on Holborn-viaduct, where the street extending from Holborn-circus to Old-bailey, the City Temple, two hotels, the entrance to the London, Chatham, and Dover Railway Station, Messrs. Spiers and Pond's Restaurant, and numerous shops and offices are lighted up from a Central Station. The Lamps give out very little heat, they may be grasped by the naked hand without danger or inconvenience, are free from odour, and give off no products of a poisonous or noxious character.

This Company, deriving as it does it rights and privileges direct from Mr. Edison, will be a parent Company. It will be prepared to undertake the business of a Lighting and Power Company, by lighting up towns, public buildings, manufactories, barracks, and residences, and supplying power by means of electricity; and in order to enlist local capital and influence will grant licenses to Corporations and local Companies to carry on a similar business.

With a view to the early commencement of active operations the Directors have made arrangements for purchasing a number of Mr. Edison's lamps, dynamos, and other materials which are now in London, ready for shipment to some of the principal centres of population and industry within the Company's field of operations. Mr. Edison has agreed, until 1st January, 1883, to supply the Company with Dynamos, Lamps, and other specialties of his system, of his own manufacture, at the prices charged by him to his most favoured customers. The Company, however, is free to obtain all such things elsewhere, or to manufacture them, whenever it shall be found more advantageous to do so.

The consideration to be paid for the property and rights secured to the Company is the sum of £25,000 in cash, 5,000 A Shares, fully paid and ranking as such for dividend, and 10,000 B Shares, fully paid, upon which no dividend will be paid until after the A Shares have received a cumulative dividend of 6 per cent. per annum. The surplus profits available for dividend, after payment of the 6 per cent. of cumulative dividend on the A Shares will be divided equally between A and B Shares until the A Shares shall have received a dividend equal to 10 per cent. The remaining profits, subject to a percentage payable to the Directors, will then be divided equally between the A and B Shares respectively. No promotion money will be paid.

The Directors are in negotiation for securing the services of an exceptionally competent Manager, who will be prepared to visit India and the Colonies whenever occasion may require.

The only agreement entered into is dated 12th June, 1882, and made between Thomas Alva Edison, of the first part; George Edward Gouraud, of the second part; and the Marquis of Tweeddale, the Honourable W. St. John Brodrick, M.P., Henry Schlesinger, Colonel the Honourable W. Le Poer Trench, and Sir George Warrender, Bart., of the third part, and which is open to inspection (together with the Memorandum and Articles of Association of the Company) at the Offices of Messrs. Bircham and Co., solicitors, 26, Austin Friars, London.

Applications for shares must be made on the form accompanying the Prospectus, to be lodged with Messrs. Glyn, Mills and Co., of 67, Lombard-street, London, E.C., or the Commercial Bank of Scotland, Edinburgh, the Company's Bankers, together with a deposit of 10s. per share. In case of no allotment being made, the amount of deposit will be returned in full. Where a smaller number of shares are allotted than are applied for, the balance of the deposit will be applied towards payment of the amount payable on allotment.

Prospectuses and Forms of Application may be had of the Brokers, Messrs. A. Anderson and Co., 30, Throgmorton-street, E.C., and at the Temporary Offices of the Company, 6, Lombard-street, E.C.

The Subscription List will be closed for London on or before Friday, the 16th inst., and for the Country on or before Saturday, the 17th inst.

12th June, 1882.

Digitized by Google

THE SCHOOL OF TELEGRAPHY & ELECTRICAL ENGINEERING.

ESTABLISHED IN 1868.

12, PRINCES STREET, CORNER OF HANOVER SQUARE, LONDON, W.

(Removed from 4, George Street, Hanover Square.)

MANAGING DIRECTOR: Mr. T. J. JONES, M.S.T.E.

The course of Practical and Theoretical Instruction in the higher branches of Overland and Submarine Telegraphy embraces, in addition to the manipulation of he various systems of working in general use, the following subjects:—

MATHEMATICS,	In relation to Telegraphy.	SIGNALLING and TESTING INSTRUMENTS.	ELECTRO-STATICS.	METHODS of TESTING the ELECTRICAL CONDITION of a LINE During and After its Construction.
MECHANICS, and			ELECTRO-DYNAMICS.	TESTING FOR and LOCALISING FAULTS, &c., &c., &c.
CHEMISTRY,		ENGINEERING FORMULÆ and their Application in Practice.	MAGNETISM.	

The instruction, both in signalling and testing, is of a thoroughly practical character, as the classes work with the actual instruments used on long lines, through cables of various lengths, from 600 to 3,000 knots, so that the signals of the Eastern, Atlantic, and Brazilian Co.'s, &c., are exactly reproduced, and the pupils fitted for any line.

A complete practical and theoretical course of instruction on the TELEPHONE and the ELECTRIC LIGHT, and their commercial utilisation, has now been added to, and embodied in, the ordinary curriculum, as the advantage of being associated with any great commercial application of science at an early period of its development is one which has been so often exemplified that it can scarcely fail to be appreciated by those who have in view professional success.

That **TELEPHONIC** communication and **ELECTRIC LIGHTING** constitute such applications is sufficiently shown by their rapidly increasing progress; and therefore no pains or expense have been spared to place at the disposal of the pupils the technical and scientific instruction requisite to qualify candidates for the most important posts in connection with these new branches of electrical engineering. In order that the instruction in the erection, adjustment, testing, and working of **TELEPHONE** and **ELECTRIC LIGHT** circuits may also be thoroughly practical, complete working telephone exchanges upon the various systems in use in different countries have been fitted up; every kind of telephone, for both exchange systems and private lines, with all apparatus used therewith, is provided (in duplicate when possible, so that students may be able to dissect and reconstruct the same). The necessary tools and materials are available, and every facility is given for conducting experiments by the pupils desirous of so doing, and a similar course is being pursued with the **VARIOUS LAMPS** and **MACHINES**, &c., in the **ELECTRIC LIGHT** Department, so that pupils from the School are in a position to enter either of these new fields.

The complete Practical and Theoretical course extends over a period of Six Months.

Arrangements have been made so that Inventors, Amateurs, and others can now have every facility, with all necessary apparatus provided in private rooms, to compare, test, or perfect any Inventions, Apparatus, &c., connected with Telegraphy, Telephony, and the Electric Light. Financial and the highest professional assistance can also be had.

Further particulars may be obtained on application to W. N. TIDDY, *Secretary.*

THE EXCHANGE TELEGRAPH COMPANY, LIMITED.

Head Offices—17 & 18, Cornhill, E.C.; Stock Exchange, E.C.; 27, Regent Street, W.

Incorporated the 28th March, 1872, under the Companies Acts of 1862 and 1867, and by Special License from H.M. Postmaster-General.

This Company will undertake to supply recording instruments, telegraphically connected with the Stock Exchange, by the aid of which Subscribers, at their respective offices, may be kept continuously advised throughout the day of the constantly occurring market fluctuations in stocks and shares.

Instruments are placed in the offices of Subscribers and kept in order by the Company, free of every expense but that of rent, and inspectors visit them daily to supply ink and paper.

Terms: £50 per annum, payable quarterly in advance.

Applications for instruments to be made to the Secretary at the above address.

Not having any springs or clockwork to wind up or to depend on, these instruments are acknowledged by those familiar with the system of telegraphy to be the only instruments yet invented that are capable of doing the work required of them continuously for a lengthened period, as evidenced by the fact that the Gold and Stock Company of New York, having the monopoly of this kind of business in the States, and which owns all the patents of the day of any value, has, after due trial, discarded all others.

The Company is prepared to treat with provincial Companies requiring instruments for the delivery of news for either single or double wire systems under the Company's patents, whereby from central stations identical information can be simultaneously delivered to any number of recipients by automatic, self-adjusting, printing instruments requiring no local batteries, no winding up, and no knowledge of telegraphy on the part of the receiver, the printing being in bold roman type, and the propulsion of the paper being effected by the electricity supplied from the Central Office.

The instruments supplied by the Company can be had to work either on single or double wires, and to print either on a slip or tape of paper, as has hitherto been the custom, or on a broad band of paper in column form.

RAMSDEN, CAMM AND CO.,

BRIGHOUSE, YORKSHIRE.

IRON and STEEL WIRE DRAWERS and PATENT GALVANIZERS.

MANUFACTURERS OF TELEGRAPH, TELEPHONE, & CABLE WIRE.

CONTRACTORS TO H.M. GOVERNMENT AND RAILWAY COMPANIES.

LONDON OFFICE: 72, KING WILLIAM STREET.

JOURNAL of the SOCIETY of TELEGRAPH ENGINEERS and of ELECTRICIANS.
Edited by Professor AYRTON, F.R.S.
No. 42,
containing Illustrated Papers on

"Tests of Incandescent Lamps for Fall of Resistance with Increase of Electromotive Force, and Ratio of Candle-power to Work done on Lamp," by A. Jamieson.

"Attraction and Repulsion due to Sonorous Vibrations, and a Comparison of the Phenomena with those of Magnetism," by A. Stroh.

"Report on Incandescent Lamps Exhibited at the International Exposition of Electricity, Paris, 1881," communicated by W. Crookes, F.R.S.

Price Three Shillings.

E. and F. N. SPON, Charing-cross.

A PRACTICAL ENGINEER and ELECTRICIAN (Assoc.Mem.I.C.E.) wishes an ENGAGEMENT. Accustomed to both Lighting and Manufacture. Highest references and testimonials.—Address, "D. E. R.," ELECTRICIAN Office.

TO ENGINEERS, ELECTRIC COMPANIES and Others. —A fine MANUFACTURING PROPERTY to be SOLD at a very low price. Close to a station. With possession.—Apply to Messrs. PRIOR and NEWSON, 57, Lincoln's Inn-fields, W.C.

FIRE RISK, &c., of ELECTRIC LIGHTING.
Mr. MUSGRAVE HEAPHY, C.E., Consulting Engineer to the PHŒNIX FIRE OFFICE, can be CONSULTED PROFESSIONALLY by all who contemplate using the Electric Light.

Mr. Heaphy will advise as to the most suitable and economical light, supervise the estimates furnished by the Electric Light Companies, superintend the installation and all matters connected therewith, giving special attention to Fire Risk and Danger.

Address—19, LOMBARD-STREET, LONDON, E.C.

P.S.—For Account of Mr. Heaphy's Report upon Electric Lighting and Rules necessary for Safety see "Times," May 10th; "Electrician," May 13th; "Journal Soc. of Arts," May 5th; "Insurance Guardian," April 26th; and most of the leading papers in England.

LIFE ASSOCIATION of SCOTLAND.
Founded 1838.
HEALTHY PERSONS OF ALL AGES will find in the BONUS SYSTEMS of the LIFE ASSOCIATION of SCOTLAND advantages far exceeding those which can be obtained under any of the ordinary systems.

Claims and Bonuses paid £4,028,000
Annual Revenue 436,000

Immediate Entrants in Class A will secure ONE YEAR'S BONUS MORE THAN LATER ASSURERS in that class.

LONDON—5, Lombard-street, and 48, Pall Mall.
EDINBURGH—82, Princes-street.

SLIP

AN ELECTRIC RAILWAY FOR PHILADELPHIA.—A narrow-gauge electric railway in Fairmount Park, Philadelphia, is proposed.

ELECTRIC RAILWAYS.—Dr. Siemens is to give a lecture on this subject in Trinity College, Dublin, on Monday next, at four o'clock.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company, for the week ending the 9th inst., amounted to £3,301.

TELEGRAPH WIRES IN ENGLAND.—According to recent statistics there are, on an average, four miles and a half of wire to every mile of telegraph line in England.

SOUTH AFRICAN TELEGRAPHS.—The telegraph receipts in Cape Colony for April last amounted to £4,889, against £5,999 for the same period of last year, or a decrease of £1,110.

THE AMERICAN BRUSH COMPANY.—It is stated that the 100-dollar shares of this company, which started two years in advance of the Anglo-American Brush Company, now stand at 7,000 dollars.

SOCIETY OF ARTS.—This Society has awarded a silver medal to Professor Silvanus Thompson, D.Sc., for his paper on the "Storage of Electricity," read during the Session 1881-82. This paper will be found in our last volume.

ELECTRIC LIGHT AND POWER GENERATOR COMPANY.—A meeting of this company is to be held on the 27th inst., when it will be proposed that the name should be changed to the "Maxim-Weston Electric Company (Limited)."

PERSONAL.—Mr. William Kingsland, A.S.T.E., &c., late superintending electrician to the Hammond Electric Light Company, has been appointed electrical engineer to the Yorkshire Brush Electric Light and Power Company.

CAIRO.—The Eastern Telegraph Company notified on the 15th instant the temporary closing of its office in Cairo. Telegrams for Cairo can only be accepted at the sender's risk, to be forwarded from Alexandria by best means.

TENDERS WANTED FOR ELECTRIC LIGHTING.—Tenders are being invited for lighting Honley Exhibition by means of electricity. For further particulars apply to the Secretary, Exhibition Committee, Honley National Schools, near Huddersfield.

ELECTRIC LIGHTING FOR TRAINS.—It is said that experiments are being made on the Alsace-Lorraine Railway with the view of lighting trains by electric light during their passage through tunnels, the motive power being supplied by the locomotive.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company, for the week ending the 9th inst., were £2,180 after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited).

THE TELEGRAPH ON THE CHINESE BORDER.—A Reuter's telegram from St. Petersburg, dated June 16, says:—"The Kuldja telegraph line will be removed, as it is being continually damaged by the Chinese. The Sinbun line is also frequently interrupted."

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company's traffics and steamer for the two months ending May 31st, 1882, amounted to £6,100, against £5,050 in the corresponding period of last year, showing an increase of £1,050.

EASTERN EXTENSION TELEGRAPH COMPANY.—This company notify that the coupon due July 1 proximo, on their Five per Cent. Australian Government Subsidy Debentures, will be paid on and after that date at the banking house of Messrs. Barclay, Bevan, and Co.

GLASGOW.—We understand that the Glasgow Post Office is to be lighted throughout by Messrs. Crompton and Co. The decision has been arrived at after a two years' careful trial of the electric light, during which time there has been a complete absence of breakdown.

ALEXANDRIA.—A telegram from the *Daily News* correspondent, dated Alexandria, Sunday, stated that the Eastern telegraph clerks had gone to live on board the company's ship "Chiltern," close to the office opened on the Peninsular and Oriental Company's premises at Gabbary.

CARDIFF.—The *Western Mail* office is now lighted throughout with Maxim incandescent lights. The lamps and dynamos have been installed by the Electric Light and Power Generator Co. The arrangements are very complete, and we hope to be able to illustrate the whole in an early number.

PROPOSED NEW CABLE.—Signor Baccarini, Minister of Public Works for Italy, recently laid a Bill before Parliament for approving a convention with the Eastern Telegraph Company for laying a cable between the Lipari Islands and the Island of Salina. The Chamber granted urgency to the Bill.

NEW TELEGRAPH COMPANY.—The Baltimore and Ohio Telegraph Company has been formed at Albany, New York. The general route of the lines is from New York to Brooklyn, thence across New York Bay to Edgewater, through Richmond County to or near Tottenville. The capital is 100,000 dollars.

PROTECTION OF CABLES.—At a meeting of the Executive Council of the Associated Chambers of Commerce on the 9th instant it was resolved that "The President be requested to make inquiries, and to press the Government to take steps for the preservation of telegraphic cables between this country and the continent."

CRYSTAL PALACE.—Major Flood Page has resigned the post of manager of the Crystal Palace, and accepted that of general manager of the Edison Indian and Colonial Electric Light Company. The Crystal Palace Company are advertising for a successor to Major Page at a salary of £750. Applications to be sent in before the 11th July.

THE FAURE ELECTRIC ACCUMULATOR COMPANY.—An extraordinary general meeting of this company will be held on the 29th inst. at the Cannon-street Hotel, at 12 noon, to receive a statement from the directors, and consider the future policy and business of the company under circumstances which will be explained to the meeting.

FRENCH TELEGRAPHS.—According to the report on the Post Office Estimates for 1883 the number of telegraph offices in France will next year be 6,448, against 4,561 in 1877. The total length of telegraph lines will have increased from 57,090 to 87,020 kilometres, whilst the increase in the number of telegrams will be 157½ per cent.

BERECHURCH HALL.—Mr. Coope, M.P. for Middlesex, has decided to light his new mansion throughout by the electric light. The Swan incandescent lamp is to be used, and the work, as in the case of the Glasgow Post Office, will be carried out, in consequence of the new arrangements with Messrs. Crompton, by the Swan United Company.

THE TELEPHONE AND THE MASSACRE IN EGYPT.—The Alexandria correspondent of the *Standard* says, in the issue of that paper for Saturday last:—"It was fortunate that telephonic communication was established between Sir B.

Digitized by Google

Seymour and the British Consulate before the riot of Sunday broke out. To this is attributed the saving of many lives that would otherwise have been sacrificed."

ELECTRIC LIGHT IN SALFORD.—Mr. M. Ruddle, engineer to the Edison company in Manchester, writes with reference to the note in our issue of June 10 on the Edison plant used by Messrs. Mather and Platt, of Salford, as follows:—"Will you kindly note for correction that the power is supplied by one quick-speed engine of 6 horse-power nominal for 138 lamps and a 2 horse-power motor, which drives several lathes. I may add that in point of steadiness the engine, which is manufactured by this firm, leaves nothing to be desired."

TELEGRAPHIC ERRORS.—The *Daily News* is responsible for the following:—"The Stock Exchange rumours of resignations in the Ministry were the subject of amused comment in the House of Commons last night (Monday, June 19). Amongst other stories current on the subject is one to the effect that, by an error in the transmission of a telegram, the message 'Bright and Chamberlain resigned' was delivered to a large operator in railway shares as 'Brighton chairman resigned,' and that he promptly proceeded to sell Brighton stock."

ROYAL SOCIETY OF EDINBURGH.—At the fourteenth ordinary meeting of this society on Monday last, Lord Moncrieff, the president, presented the Keith prize for the biennial period 1879-81 to Professor Chrystal for his paper "On the Differential Telephone." After the reading of several other papers, Dr. A. Macfarlane stated the outcome of experiments described in a paper by himself and Mr. D. Rintoul, M.A., on the "Effect of Moisture on the Electric Discharge," to be such as to justify the conclusion that the drying of air increases the resistance to the disruptive discharge. The paper referred to was given in our last volume.

THE BOTANICAL GARDENS.—On Thursday night at the annual *fête* the conservatories and the principle tent were ighted by means of Maxim incandescent and Weston arc lamps. The arrangements were carried out by the Electric Light and Power Generator Company. Three Maxim machines, driven by a Ransome's portable engine, generated the current for about 250 Maxim lamps, and one Weston machine was used to obtain the current for ten Weston arc lamps. The President of the Society, the Duke of Teck, interested himself greatly in the lighting, and suggested some of the arrangements, which were admirably carried out.

ELECTRIC LIGHT AT THE CRYSTAL PALACE.—The Crystal Palace authorities have decided to continue the lighting of the terrace throughout the coming summer months by the André system of electric lighting, and have sanctioned the extension of the system to the track and station of the new electric railway which is about to be opened in the grounds. The terrace is now lighted by 12 arc lights of the kind designed by Mr. André for street lighting, and the railway track will be illuminated by four arc lamps of another type, intended for general lighting purposes. The railway station will be lighted by 30 André incandescent lamps. This new railway will be opened in a few days.

CENTRAL AND SOUTH AMERICAN CABLE.—The India Rubber, Gutta Percha, and Telegraph Works Company have received a telegram from Mr. R. K. Gray, engineer-in-chief, dated Panama, 13th instant, stating that the "Silvertown" and "Retriever" were then coaling at Panama. Mr. Gray expected that the Buenaventura-Panama section of the cable would be completed by the 20th instant. Another telegram received by the company from their ss. "International," says that the cable she had on board for the Mexican cables extension has been successfully laid, and that she intended going to Brazos to splice the Tampico-Brazos section to the cable now laid to Galveston.

ELECTRIC LIGHT AT STAFFORD HOUSE.—On Friday last the Duke of Sutherland invited a number of gentlemen interested in electric lighting to see the incandescent system as it has been applied to his town residence, Stafford House, by the British Electric Light Company. The total number of lamps in use is 258, of 20 candle-power each. The picture gallery, which is 123ft. in length, is lighted by 176 lamps, and the banqueting room, 62ft. long, by 73 lamps. The machinery has been temporarily erected in the garden. There are six Gramme dynamo machines. The whole of the work has been carried out in five weeks. The lighting was continued on Friday night for about two hours, and gave great satisfaction to those present. The company are to be congratulated on the way in which the installation has been effected by their engineers.

TELEPHONE LICENSES.—In the House of Commons on Thursday week, The O'Donoghue asked the Postmaster-General whether, taking into account that nearly a month had elapsed since he informed the House that he was considering the application of the London and Globe Telephone and Maintenance Company for a license, he could now state the decision at which he had arrived; and, if not, within what period he expected to be able to announce his decision.—Mr. Fawcett replied that the question as to the granting of telephone exchange licenses involved many important and difficult issues. The subject had been for some time engaging his careful attention, and, although he regretted that he could not fix the precise time when he would be able to announce a decision, he assured the hon. member that there should be no unnecessary delay.

ELECTRIC EXHIBITION AT MUNICH.—It is stated that the Bavarian Postal Telegraph and Railway Department have placed at the disposal of the committee of the above exhibition a train for experimenting with the electric light as an illuminant for the carriages, and also as a headlight for the locomotive. Long lines for telephonic experiments have likewise been placed at their disposal by the same department; the longest of these lines is said to be that between Munich and Dresden, a distance of 550 kilometres. It is expected that at least 3,000 horse-power will be obtained from the river Isar, and transmitted by means of electricity to various places, there to be reproduced in the shape of light and power. A special committee has been appointed to report on the electric light systems shown, and if deemed advisable, to adopt one as a means of illuminating the streets of the town.

SIXPENNY TELEGRAMS.—In the House of Commons on Thursday week, Mr. Stanhope asked the Postmaster-General whether he would lay upon the table the correspondence which had passed between him and the Committee of Lloyd's with reference to a proposal to adopt a sixpenny rate for certain telegrams, and an undertaking on the part of the Committee to indemnify the Government against any loss that might accrue from the experiment. In reply, Mr. Fawcett said:—"It is not usual to lay on the table such correspondence as that to which the hon. member refers, and I regret, therefore, that I am not able to comply with his request. I may, perhaps, add that in declining the proposal to which reference is made I was mainly influenced by the opinion that whenever sixpenny telegrams are introduced they should not be confined to any particular company or association, but that the public generally should participate in the change."

International Telegraph Statistics.—According to statistics recently issued by the International Bureau of Telegraphic Statistics at Berne the total length of telegraph lines at the present time is:—Russia, 50,090 miles; Germany, 44,265 miles; France, 43,650 miles; Austria-Hungary, 31,015 miles; Great Britain, 26,465 miles; Italy, 16,430 miles; Sweden and Norway, 12,625 miles; Switzerland, 4,097 miles; and Belgium, 3,505. The length of wires in the various countries is as follows:—Germany, 159,910 miles; Russia, 134,465 miles; France, 125,265 miles; Great Britain, 121,720 miles; Austria-Hungary 89,960 miles; Italy, 53,692 miles; Sweden and Norway 28,445 miles; Belgium, 16,345 miles and Switzerland, 10,010 miles. The total number of messages sent during the past year are classed as follows:—England, 29,820,445; France, 19,882,628; Germany, 16,312,457; Austria-Hungary, 8,729,321; Russia, 7,298,422; Italy, 6,511,497; Holland, 3,109,230; and Sweden and Norway, 2,028,805.

Electric Light in India.—We take the following from the *Homeward Mail* of recent date:—"A correspondent, writing from Indore on May 26, says:—'The Queen's birthday was celebrated with due ceremony by the usual parades of troops at Indore and Mhow. . . . In the evening a banquet was given by Appia Bolia Sahib, son-in-law of Maharajah Holkar, in the Residency Grounds, to the Agent, Governor-General, and all the political and military officers of Mhow and Indore. The lawns and gardens on the banks of the river were superbly lighted with electric lamps furnished from Bombay by the Eastern Electric Light and Power Company. The distinguished firm of Kibbio Boos, a family whose name is intimately associated with Central Indian history, gave last year, on the Queen's birthday, a similar entertainment, which was considered a brilliant success; while the *fête* of the present year has been remarkable for introducing for the first time and on a large scale the electric light into Central India.'"

Accumulators and Tramways.—In an article dealing with the various powers used on tramways—viz., horse, steam, and electric, our excellent contemporary, the *Builder*, points out that the reason steam has not succeeded as a motive power for tramways is its excessive cost. According to our contemporary's figures it costs "16d. to do on a tramway what it costs 2d. to do on a railway, and two-thirds of a 1d. to do on a canal." The article concludes as follows:—"It is in the direction of the use of electric power by accumulating batteries that we think the best prospect of mechanical tramway working at present offers itself. It is well known to be the fact that it is the strain of starting the cars that most tries the horses, and that, in fact, makes the horse-power so costly. We ventured to anticipate that the most successful mode of tramway working which at the present time is attainable is the use of horse traction, supplemented by a starting force to be supplied by an accumulator, which might also receive the force otherwise wasted in stopping."

The Electric Lighting Bill.—It is stated that an effort will be made to prevent the passing of the Bill this Session, and that pending the selection of some more important leader, Mr. Warton has undertaken to block the Bill. In the House of Commons, on Monday, Colonel Makins gave notice that he should move that it was undesirable to retain in the Bill the novel powers proposed to be given to the Board of Trade to grant licenses to local authorities, companies, or persons enabling them to exercise powers which had hitherto only been granted by Act of Parliament, or by provisional orders confirmed by Act of Parliament, and that the Bill be referred back to the committee with instructions to strike out all provisions authorising the granting of such licenses by the Board of Trade. Mr. Kynaston Cross has also proposed an amendment to the Bill, the object of which is to obtain payment for the undertakers, in the event of purchase by a local authority, either wholly or in part, for the goodwill, to an amount not exceeding 25 per cent. on the structural value of the concern.

New Companies.—The Markland Electric Lighting Power and Regulator Company has been formed, with a capital of £200,000, to work the Markland arc lamp and regulator in England. The lamp is an American invention. Mr. J. A. Barrett has been appointed consulting electrician, and Mr. J. A. Graham electric engineer, to the Company. The offices are at 8, Tokenhouse-yard, E.C.—The Anglo-Spanish Brush Electric Light and Power Company has a capital of £200,000, and will work the Brush and Lane-Fox patents in Spain and its colonies.—The Telephone Company of Ireland has a capital of £200,000, and has obtained a license from the United Telephone Company to use their telephones and apparatus in Ireland (excluding the Province of Ulster). The company has also acquired the existing business of the United Telephone Company in Dublin. Professor W. Barrett, F.R.S., is consulting electrician.—The Electric Lighting Supply and Fitting Company has a capital of £20,000, and has been formed to work Mr. Killingworth Hedges's patents. Its offices are at Victoria-mansions, Westminster, S.W.—The United Kingdom Economic Electric Light and Power Company has a capital of £500,000. It has been registered by Messrs. Cridge and Bell, 26, Bishopsgate-street Within, E.C.

The Telegraph Conference at Barbadoes.—The *Colonies and India* says:—"A conference of delegates, representing all the British colonies in the West Indies except Jamaica and the Bahamas, summoned by direction of Lord Kimberley to consider the best means of improving telegraphic communication between this country and our possessions in that part of the world, has been sitting at Barbadoes for some time past. After carefully examining into the various interests involved the delegates have recommended the adoption of a scheme which has been more than once urged in these columns during the last six or eight years, viz., the establishment of a line of cable connecting all the British West Indian Islands with Halifax, Nova Scotia, *vià* Bermuda, thus affording a means of communication exclusively through British territory. The cost of such a cable is estimated at a million sterling, and it is proposed that the expense should be borne in equitable proportions by the Home Government and the various colonial Governments. The advantages of such a scheme are self-evident. Bermuda and Halifax, the principal naval stations in the Atlantic—the one stationed, sentinel-like, far out towards the middle of the ocean, the other on the mainland—would be placed in close connection with each other, and would link our important West Indian possessions directly with the rest of the Empire. The value of Bermuda, from a strategical point of view, would be vastly increased; while it would also be able to serve the hardly less valuable purpose of a meteorological station, giving timely warning of the approach of storms across the Atlantic. At present we are dependent for West Indian news on intelligence transmitted through the United States. In the event of war such a state of things would be intolerable."

The Telegraph in Egypt.—The following letters appeared in *The Times* of June 19 and 20 respectively. The first is signed "E. A. Floyer, Inspector-General of the Egyptian Telegraphs," and is dated from the Royal Geographical Society. It reads as follows:—"Sir: This morning a gen-

Digitized by Google

tleman told me that on offering a telegram to Cairo it was refused, and he was told that it could not be sent further than Alexandria. He happened to know Egypt well, and insisted on his telegram being despatched. But the refusal may be made to other people less able to expose its absurdity, and it is to prevent such error that I beg you to insert this letter. The condition of the Eastern Telegraph Company's wires between Cairo and Alexandria is of the smallest moment to telegraph communication between those places, which is still less affected by the 'removal of the European telegraph office from Cairo,' announced in the papers as if of some significance. The lines of his Highness the Khedive, maintained by Egyptian engineers and worked by European and Egyptian clerks, are amply sufficient for any number of messages they are likely to get, and can, as before, lend the Eastern Company a wire if theirs are broken down." To this Sir James Anderson, managing director of the Eastern Telegraph Company, replied:—"In reference to Mr. Floyer's letter in *The Times* of this date (June 19) I beg to say that no messages for Cairo have been refused at the offices of this company, and if the Post Office have done so we have no information of it. It was only after the most urgent warning to our people at Cairo that 'the time for illusions was past, and that their safety was imperilled,' that the office was temporarily closed, the staff professing their eagerness to remain until the last moment. The directors did not think it their duty to imperil men's lives when the traffic could equally well be transmitted with comparative safety. The communication is as rapid as ever it was, with the single exception of runners being employed between the temporary station in the harbour and the office in the city of Alexandria."

THE ELECTRIC LIGHT FOR THE CITY.—At a meeting of the Commissioners of Sewers on Tuesday, a motion, "That it be referred to the Streets Committee to consider whether steps should not be taken to provide that all arrangements in regard to electric lighting within the City, whether of public ways or private premises, necessitating interference with the pavements, be undertaken by the Commission," was agreed to. It was likewise referred to the same committee to consider a memorial of merchants and traders, asking that any systems of electric lighting adopted by the Commissioners might be utilised for the convenience and benefit of private houses. The memorial stated that the subscribers to it, who were large contributors to the rates, had viewed with approval the action of the Commission in experimentalising in street lighting with the electric light, and pointed out that they were now very largely under the power of the gas companies, and that it would be much to their benefit if they had the choice of using either gas or the electric light. Many of the memorialists would be willing to enter into contracts with the electric companies to supply them with the light from cables laid in the street; but they found that electric engines on their own premises were the only means by which they could obtain the electric light. They, therefore, prayed that the Court would grant to such of the electric lighting companies as it might think fit the right of lighting private houses, shops, and warehouses, any contracts entered into being for a period of not less than three years. The chief points urged by the deputation which presented the memorial were that the permanent way or pipes should be laid down by the Commissionrs of Sewers, and every facility given to the petitioners and others to be supplied from the mains with the electric light. The Streets Committee, reporting on their proceedings relative to the applications made for an extension of the experiments in electric lighting, submitted an abstract of tenders received, and expressed an opinion that it was not desirable to proceed further until Parliament had decided the principle upon which electric lighting generally shall be permitted. It appeared from the tenders included in the report that the estimated cost of applying the electric light to the four districts into which the principal City streets had been mapped out varied from £9,500 to £17,000. In one instance the lowest contract in one district was £2,190, and the highest £5,700. The gas consumed in the whole of these districts was only £1,860 per annum.

THE RIOT AT ALEXANDRIA.—The following account of the late riot at Alexandria, written by a member of the Eastern Telegraph Company's staff at Alexandria, has appeared in the daily press:—"I had better give you my personal experience of what occurred. At three p.m., five of our fellows went out boating in the harbour. Having been on night duty, I was asleep until a quarter to four, when I went out with two others to see some friends. As we arrived we heard a shot fired, followed soon after by two more. We took no notice, but went upstairs, where we found them all loading rifles and guns, in case of a rising, which, they said, had been threatening for some time. There were two ladies (to whom the house belonged) and the captain of one of the ships in the harbour. So it was proposed to send the women on board, in case of accidents. They were sent off with the captain and another man. Whether they got on board safe or not I don't know, but God help the poor girls if they got into the hands of those brutes of Arabs. We then went back to quarters and got our revolvers. There were four of us, and we determined to go to the harbour and warn the other men not to come up, or else to come immediately, before the row commenced. We drove all right until we got to the turning down to the landing-stage, when all of a sudden a crowd of Arabs rushed round the corner, shouting 'Down with the Unbelievers!' 'Death to the English!' Before we knew where we were we got beaten about the head with sticks. We all got out of the carriage, revolvers in hand. As I was alighting an Arab caught me a fearful blow on the top of the head with a stick. I marked him, aimed carefully, when I found that my revolver had got jammed somehow, and would not fire. I cocked it and levelled again, but the thing would not go off. Almost at this moment I received a tremendous blow on the top of my scull, and another on my wrist, which knocked my pistol out of my hand. I stooped to pick it up, when I received a stroke on the back of the head, which I shall not soon forget. It struck me that I should be no good to the other fellows if I stayed, so turned and fled for a good half mile. I ran the gauntlet up the street streaming with blood, either dodging or else going straight at the Arabs and striking with my fists somehow or other. I was covered with blood, and was just sinking when I espied a chemist's shop open, rushed in, and sank on a chair. As it happened, I arrived at the right moment and in the right place, for there were sixteen young medical students, well armed to the teeth, one of whom dressed my wounds and gave me some lemonade, and made me lie down on a divan, with orders not to say a word, assuring me that I was quite safe. I sent a note to our quarters, and at nine in the evening they sent four men, well armed, to fetch me. One of my other comrades turned up; the remaining two have not been heard of. A party has been sent to the hospitals and Consulates to search for them, and, dead or alive, to find them. There is still hope they may have taken refuge somewhere and may turn up. I lost my revolver, watch chain, one shoe, my hat, and stick."

THE PHENOMENA OF THE ELECTRIC DISCHARGE WITH 14,400 CHLORIDE OF SILVER CELLS.*

BY WARREN DE LA RUE, ESQ., F.R.S., SEC.R.I., ETC.

(CONCLUDED FROM PAGE 103.)

The effects described were produced with 8,000 cells, but with 11,000 cells we obtained a further confirmation of them, the effects being shown in another figure on the diagram (Fig. 17), which represents a streamer discharge between two points. The negative discharge is a brush which is seen continuously on the lower terminal, while the positive consists of a series of intermittent, ever-changing spiral streamers which envelop the negative brush discharge without in the least disturbing its form. They go past the negative point and then curl up towards it.

If I insert a very high resistance between the battery and the terminals the streamer discharge ceases, and a static spark

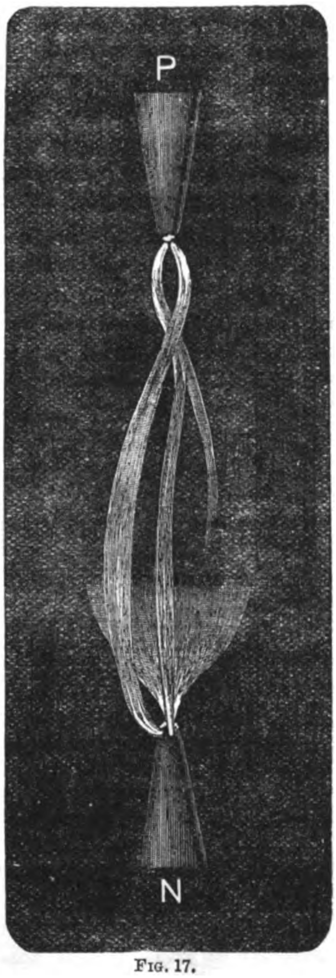

Fig. 17.

passes from time to time which is exactly like that from an ordinary frictional machine; it pierces a thin strip of paper just as a static charge would do. The battery gathers up at intervals a charge at the terminals, and the discharge occurs as soon as the potential is sufficient to force its way across the obstacle opposed by the intervening air.

The same thing occurs if I attach a condenser to the terminals of the battery; it takes a longer time for the battery to charge it, and consequently the discharge occurs at longer intervals, shorter or longer according as the terminals are adjusted to a less or greater distance. The condenser I am now using has a capacity of 1·5 microfarad, and hence the accumulated charge is very considerable, and the discharge is like that of a powerful electric battery. But whether the capacity of the accumulator be large or by comparison infinitesimally small like that of the points in the discharging micrometer, there is always an interval of time which elapses between successive discharges; the interval may be so extremely minute that thousands of millions of discharges may occur in a second, but the flow is discontinuous, like the stream of water before referred to.

I will endeavour to prove to you that an apparently perfectly steady discharge through a vacuum tube, in which there is no apparent motion of the strata, and in which even the rotating mirror would fail to detect any intermittence, is nevertheless discontinuous. It is true that the period of pulsation must be of a very high order, millions in a second, and it is necessary, therefore, to have recourse to special means in order to detect it, which I will describe.

The current from the battery of 2,400 cells is made to pass through the primary of an induction coil, and then through a vacuum tube (No. 142, Fig. 11 in the plate*) containing a residue of carbonic acid at a pressure of 0·4 millimetre. The arrangement is shown in Fig. 18, where T T′ is the vacuum tube connected in circuit with the primary of coil 819; Z A the battery, on the A side connected with fluid resistances F R, F R′, and wire resistances amounting in all to

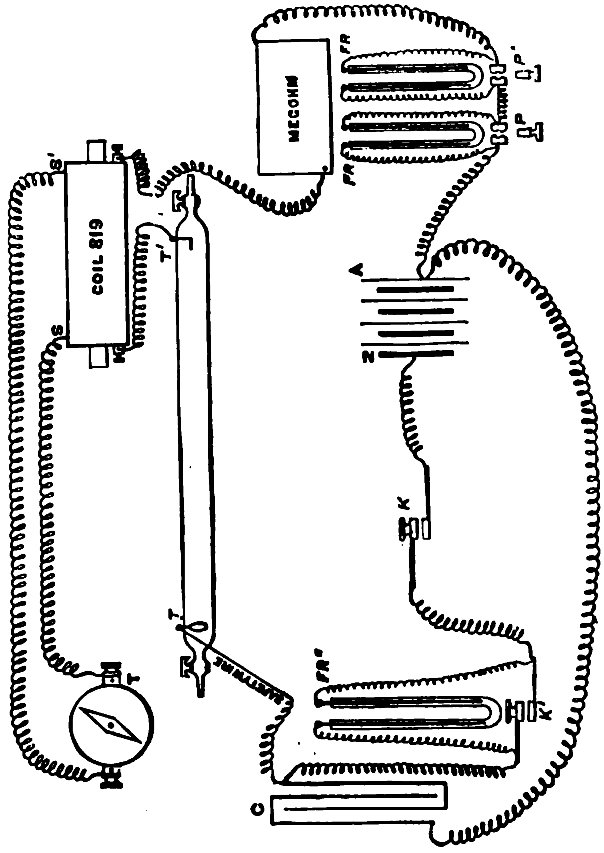

Fig. 18.

a megohm. On the Z side is shown a condenser C, connected through a fluid resistance F R″ with the Z pole. The terminals of the secondary wire of the induction coil are connected with a sensitive Thomson galvanometer. If there is any intermittence in the current through the tube, an effect will be produced on the galvanometer *under certain circumstances*, that is, provided the rise and fall of the current occur in unequal periods. I will now make connection with the battery. You perceive that there is a deflection of the galvanometer to the left on making contact; I will now allow the spot of light to come to rest, and then break contact, and there is a deflection in the reverse direction, that is, to the right. The first is called the inverse current, the last the direct current. I will now send the current again through the primary of the induction coil and thence through the tube, but in the first instance I will short-circuit the secondary current so that the galvanometer may not be disturbed when the connection with the battery is made. Now that the strata

* Reprinted, by permission, from the *Proceedings* of the Royal Institution.

* The Plate referred to here and in several places further on appear only in the original *Proceedings*.

Digitized by Google

are perfectly steady, I will allow the induced current to go through the galvanometer by removing the short-circuit plug, and you see that there is a slight *permanent* deflection of the galvanometer. This shows that the discharge in the vacuum tube, although apparently quite steady, is a pulsating one; as the swing is to the right we know that the current is a direct or break contact one, thus indicating that the discharge through the tube increases comparatively slowly, then drops more suddenly. If the rise and fall were in equal times, there would be no deflection of the galvanometer.

If the terminals of a telephone are placed in the circuit between the battery and a vacuum tube, the pulsations are sometimes sufficiently slow to produce audible sounds when the telephone is placed to the ear. But the telephone is not adapted to render evident intermittences of a very high order.

There is a remarkable phenomenon which occurs when a charge is sent through a closed vessel containing air or gas,

The discharge, in the bell jar, was photographed on one occasion, and the central spindle or arc proper was measured on the photograph, and a calculation made of what its temperature must have been on the supposition that the sudden dilatation might be due to it, and the result was 16000° Cent. Experiments were also made to ascertain the temperature of different parts of the arc, and it was found that platinum wire 1-1000th of an inch in diameter was immediately fused, but there was no vaporisation of the platinum, which certainly would have occurred had such a temperature as 16000° Cent. existed. It was ultimately concluded, from a number of experiments and considerations, that the enormous and sudden dilatation could not be attributed to a sudden increase of temperature, but must be caused by the scattering of gas molecules away from the terminals, and their projection by electrification against the walls of the containing vessel.

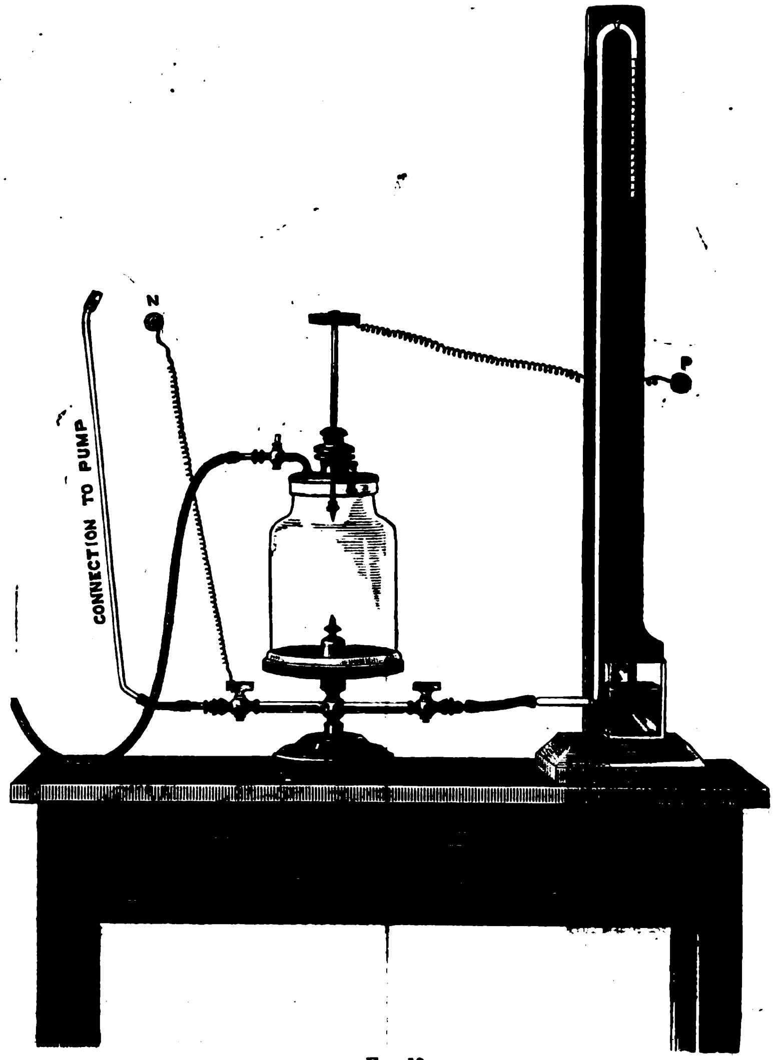

FIG. 19.

within certain limits of pressure, which I will endeavour to show you. As soon as the connection is made between the battery and the terminals a sudden expansion of gas takes place, as you will see (Fig. 19) by the depression of the mercury in the gauge connected with the bell jar, and as soon as the connection with the battery is broken the gas returns suddenly almost exactly to its original volume, showing only a small increase due to a slight elevation of temperature; the mercury in the gauge rises, therefore, nearly to its original position. The effect is similar to that which would be produced if an empty bladder suspended between the terminals had been suddenly inflated and as suddenly emptied. The ratio of the increased volume (pressure) to the normal volume in our experiments rose sometimes as 1·71to 1, and in others there was scarcely any appreciable increase; in the present instance it is as 1·4 to 1.

We have proved experimentally that the discharge in a vacuum tube does not differ essentially from that in air and other gases at ordinary atmospheric pressures; it cannot be considered as a current in the ordinary acceptation of the term, nor as at all analogous to conduction through metals, and must consequently be of the nature of a disruptive discharge, the particles acting as carriers of electrification. For example, a wire having a given difference of potential between its ends can permit one, and only one current to pass; whereas we have found by accurate measurements that with a given difference of potential between the terminals of a vacuum tube, currents of strength varying from 1 to 135 can flow.

We have found, moreover, that the resistance of a vacuum tube, unlike that of a wire, does not increase in the ratio of the distance between the terminals. As an example may be

Digitized by Google

cited that, in a Spottiswoode tube (Fig. 20) with one shifting terminal, which can be placed at any required distance from the other, for seven times the distance between the terminals the resistance was found to be only twice as great. Moreover the fall of potential is not uniform for equal increments of distance between the terminals of a vacuum tube as it is for equal increments of the length of wire. In order to determine this we used a tube with seventeen rings inserted in it at equal distances (Fig. 20); to these were attached wires which projected through the tube, and were soldered to it. One pole of the battery was connected to No. 1 ring

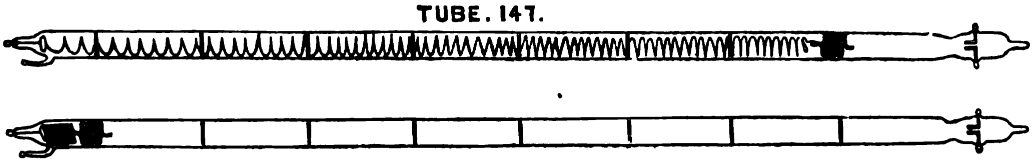

Fig. 20.

of the tube, and the last ring as well as the second pole of the battery were connected to earth and stood at zero. By means of an electrometer, shown in Fig. 21, the induction plate of which could be made to communicate with each

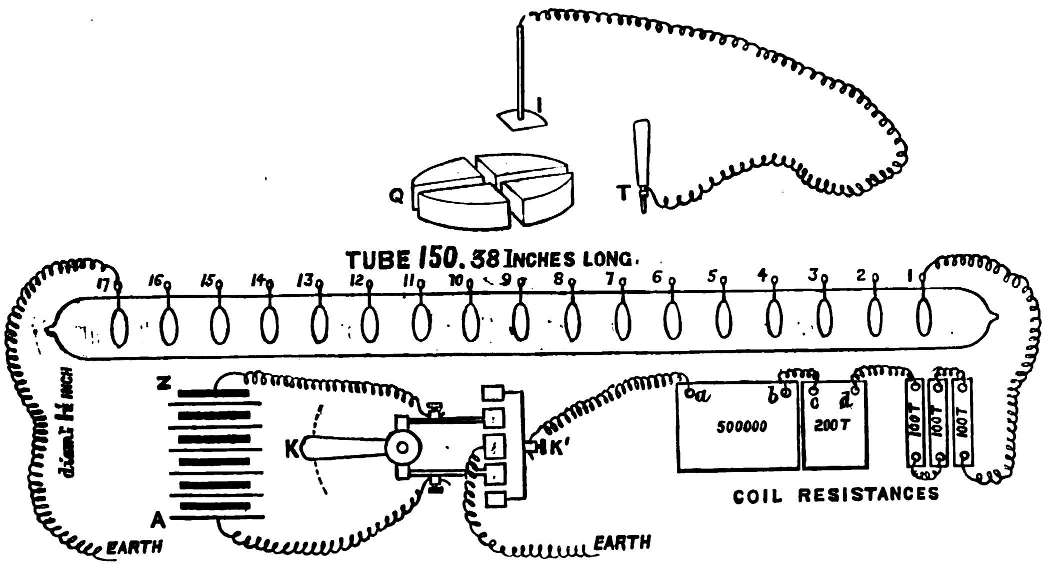

Fig. 21.

ring successively, it was found that the difference of potential between the first pair of rings, reckoning from the terminal connected with the battery, was five times as great as that between the eighth and ninth; again, that between

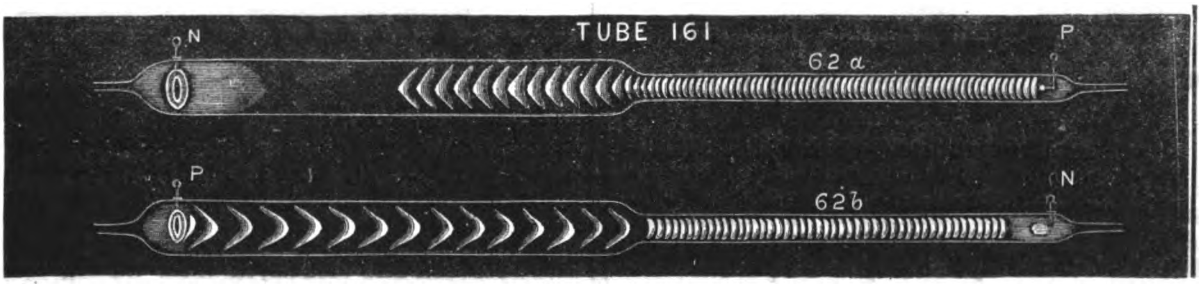

Fig. 23.

the sixteenth and seventeenth it was twice that between the eighth and ninth. If I, by way of illustration, suspend a number of pith balls to a wetted thread, one end of which I connect with one pole of the battery and the other to earth, the other pole of the battery being also connected to earth, you will notice a uniform decrease of divergence of the balls, because the potential decreases uniformly for equal distances, whereas this does not occur when pith balls are suspended to the rings of a vacuum tube, as you will see when I connect the first ring to one pole of the battery and the other to earth.

We will now take up the phenomena exhibited by vacuum tubes. It will be seen that the strata have their origin at the positive pole. Thus, in a given tube, with a certain gas, there is produced at a certain pressure, in the first instance, only one luminosity, which forms at the positive terminal; then, as the exhaustion is gradually carried further, it detaches itself, moving toward the negative, and being followed by other luminosities, which gradually increase in number up to a certain point. This I will show you, with Mr. Cottrell's aid, by projecting copies of photographs, made in my laboratory, from tubes containing hydrogen at gradually decreasing pressures.

If I now connect the fixed terminal of the Spottiswoode tube, containing residual carbonic acid at a pressure of 1 millimetre, with the positive pole of a battery of 2,400 cells, having first caused the movable terminal (which I have connected previously to the negative pole) to approach quite close to the positive wire, you will see only one stratum. I incline the tube and allow the negative terminal to recede. Now there are three strata (Fig. 10 in the plate), and as the negative recedes further and further fresh strata pour in one by one from the positive until the whole tube is filled to within a constant distance from the negative with our electric drops (Fig. 9 in the plate).

I may here pause to draw attention to the resemblance of the strata produced by an electrical discharge in a vacuum tube to the lycopodium records of sound-pulsations in air in Tyndall's work on "Sound" (Fig. 22, next page).

With the same potential the phenomena vary with the amount of current which is allowed to pass through the tube, and this amount we can easily regulate by inserting resist-

Digitized by Google

ances between the battery and the tube. As the current is increased the number of strata in some tubes increases, but with other tubes the number decreases.

A change in the amount of current frequently produces an entire change in the colour of the strata. For example, in a hydrogen tube from a cobalt blue to a pink (Figs. 4 and 3 in the plate). It also changes the spectra of the strata. Moreover, the spectra of the illuminated terminals and those of the strata differ; usually the most brilliant spectra are obtained from the negative terminal.

If the discharge is irregular and the strata indistinct, an alteration of the amount of current makes the strata distinct and steady; most frequently a point of steadiness is produced by the careful introduction of external resistance; subsequently, with the introduction of more resistance, a new phase of unsteadiness, and still more resistance, another phase of steady and distinct stratification.

At the same pressure, and with the same current, the diameter of the tube affects the character of the stratification (Fig. 23, preceding page), as will be seen when I cause the current to pass in tube No. 161, which contains residual hydrogen. It consists of two portions, one 18 inches long

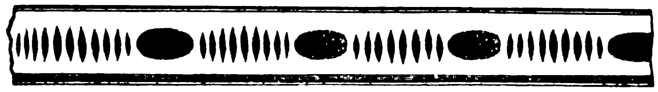

Fig. 22.

and 1·15 internal diameter, the other 17·5 inches long and 0·975 inch diameter. The battery I am using consists of 4,800 cells, and you perceive that whether the terminal in the small tube is positive or negative there is a marked difference in the form and closeness of the strata in the two tubes.

The greatest heat is developed in the vicinity of the strata. This fact we established most easily when the tube contained only one stratum, or a small number separated by a broad interval. There is reason to believe that even in the dark discharge like that in the neighbourhood of the negative terminal there may be a kind of stratified formation, for we have found a development of heat in part of a tube in which there was no illumination except on the terminals.

There are vacuum tubes made which are not open from end to end, and which consist of a number of separate chambers, some inserted into the others. The induction coil illuminates these very beautifully, but the battery will not do so, as no discharge can take place through them. On the other hand, the alternating currents of an induction coil charge up such a tube first with positive, then with negative,

TUBE 123.

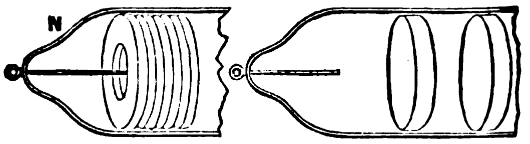

Fig. 24.

electricity, and produce an illumination in consequence of the alternating charge and discharge of the walls of it. When I turn on the battery current you will perceive a flash, then if I reverse the current another flash, and if I do this quickly I make the illumination a little more persistent. But I have a rapidly reversed commutator by which I can reverse the current 350 times in a second, and you see that with its help I can illuminate the tube very beautifully.

In almost every case there is a dark interval near the negative terminal, but occasionally we have met with tubes in which the strata completely fill the tube, the last ones threading themselves on the wire used for the negative terminal (Fig. 24). Unfortunately I have not one which I can show you, as these tubes which have shown this phase completely change after the current had passed a very short time.

I now propose to show, with the aid of my two assistants, Messrs. James Fram and Ernest Davis, some tubes with various gases at different degrees of exhaust, in order that you may see the strata in all their beauty and witness the changes of which I have spoken.

I will in the first place show a tube in which there are produced a series of luminosities like those in one of the photographs which were projected on the screen. It is No. 148, with residual hydrogen at a pressure of 4 millimetres, and connected with 7,920 cells. Fig. 8 in the plate shows the phenomenon; it is from a photograph obtained in four seconds.

Tube 201, shown by Fig. 7 in the plate, is a hydrogen vacuum at a pressure 0·8 millimetre; with 3,600 cells and an interposed resistance of 1,500,000 ohms, a perfectly steady close stratification is produced. The figure is copied from a photograph obtained in three seconds.

Tube 139, shown in the plate by Fig. 4, is a hydrogen vacuum, pressure 0·8 millimetre, with 3,600 cells and an interposed resistance of 200,000 ohms. A series of beautiful blue double strata are produced, with a carmine line between the double strata. The figure is copied from a photograph obtained in one and a half second.

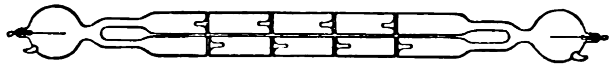

Fig. 25.

Tube 139.—On interposing 500,000 ohms resistance in the circuit, instead of 200,000, the strata are reduced in number and turn pink. The phenomenon, except as regards colour, is shown in the plate (Fig. 6), copied from a photograph obtained in three seconds.

Tube 130, a hydrogen vacuum 0·8 millimetre, with 2,400 cells and an interposed resistance of 60,000 ohms. A series of tongue-shaped strata are produced, which cross each other like the components of the letter X, and remain perfectly steady. The phenomenon is precisely like that shown by another tube, the photograph of which you saw projected on the screen. Tube 130 is represented in the plate (Fig. 6); it is copied from a photograph obtained in two and a half seconds.

Tube 333 is a hydrogen vacuum, pressure 0·8 millimetre, with 3,600 cells and an interposed resistance of 1,500,000 ohms. There are produced a series of double-tongued shaped strata, united at their narrowest parts. This phenomenon is represented in Fig. 5 in the plate, which is copied from a photograph obtained in three seconds.

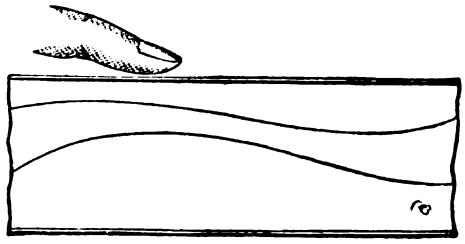

Fig. 26.

Before showing the next tube, I will exhibit one (No. 51) with a carbonic acid vacuum, in which the negative terminal consists of a wire 19in. long formed into a helix, the positive being a ring. On passing the current from a battery of 1,200 cells through the tube, first interposing a resistance of 500,000 ohms, about two inches only of the negative is illuminated; on gradually, however, removing the resistance, more and more of the spiral negative glows, until at last the whole of it is brilliantly illuminated. It will be seen by this that the negative discharge requires a greater outlet than the positive.

I will now exhibit a tube (No. 163), Fig. 25, consisting of two branches united at the top and bottom. In each of these is a series of funnels, the broad end of which fills the branch; in one branch the mouths of the funnels are placed in a con-

Digitized by Google

trary direction to that in the other. On connecting the terminals with the battery of 3,600 cells, the current is free to pass either in both branches, or through one or the other, but it invariably passes down that branch in which the wide mouth of the funnel is towards the negative. It traverses alternately the right or left hand branch, according as I make the top or bottom terminal negative; thus again exemplifying the necessity for a greater space for the negative discharge to pass than is required for the positive. The phenomenon is shown in Figs 11 and 12 in the plate.

The photographs from which the figures in the plate are copied were taken in my laboratory by Mr. H. Reynolds, on dry plates.

Very frequently, when the exhaust is very great, the discharge becomes most sensitive to the approach of the finger or any conductor in connection with the earth, or charged by a separate source of electricity; the same thing occurs if the current is made intermittent by an interval of air in one of the connections (an air spark). See Fig. 26.

The preparations which were necessary in order that this lecture could be given have occupied a considerable time. In the first place, most of the tubes I have shown you had to be specially prepared, during the last three months, and reserved for this occasion. For all tubes completely alter their character if a current is repeatedly passed through them, and then they no longer present the beautiful phases of stratification you have witnessed. Moreover, it was not possible to remove the battery from my laboratory, as its contruction would not permit it. I therefore have had built up by Messrs. Tisley and Co. an entirely new series, in such a way that the battery can be carried away, when requisite, without injury. The construction of the battery was commenced in June, 1879, and was finished in August, 1880. The charging of the battery occupied a fortnight, and was finished in the second week in December.

It only remains for me to thank you for your flattering attendance under such adverse meteorological conditions.

HEDGES' PATENT SHUT OFFS AND SWITCHES.

These switches, which were first introduced by Mr. Killingworth Hedges at the Paris Electrical Exhibition, have

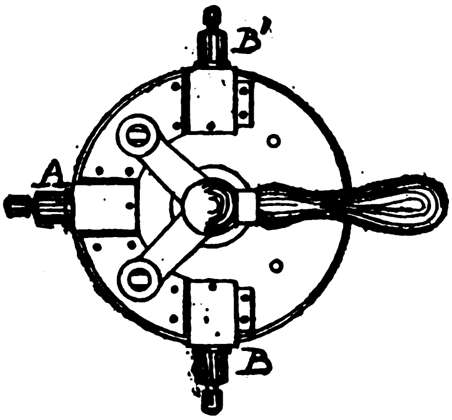

Fig. 1.

been steadily increasing in favour ever since. About eight varieties are now made to suit the strength of the current, and the number of directions into which it is necessary to shunt the current. The tendency to spark, and consequent destruction which takes place at the moment of breaking contact, is considerably obviated in Mr. Hedges' plan of causing the contact piece to slide on to a block of highly insulating and non-inflammable material, such as vulcanised fibre. With switches designed for powerful currents, the spark itself is considerably reduced by splitting the current into two or more portions. Fig. 1 shows the duplex switch of two directions on this principle for currents up to 50 amperes; the current enters at A and leaves either at B or B', according to the direction required. Fig. 2 is a switch employed with secondary batteries, for the purpose of either increasing the number of incandescent lights or the power of any set of lights. The current is increased by turning the handle to slide on to the set of contacts which are severally connected up to an increased number of cells of the secondary batteries. These switches were used at the Crystal Palace Exhibition both with the Faure and Sellon-Volckmar batteries. Another modification of Mr. Hedges' principle is shown in

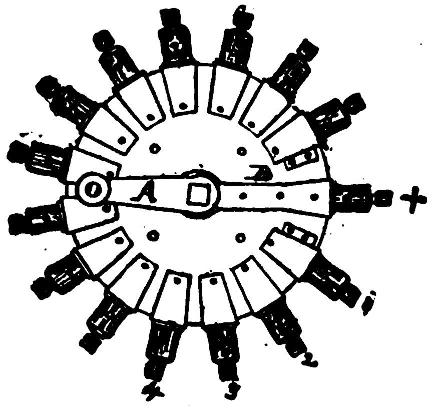

Fig. 2.

Fig. 3, which represents a reversing switch and shut off. Sir William Thomson has found that an action goes on in the incandescent lamp which tends to thin the carbon filament on the side where the current enters, and for this reason an alternating current has been preferred for these lamps. A direct current is, however, more generally used, and the disadvantage referred to can be removed by reversing the direction of the current occasionally. To do this, it is only necessary to connect the two terminals of the dynamo with those marked A and C in the drawing, the lamps being on this line connecting D and B. As shown the current will

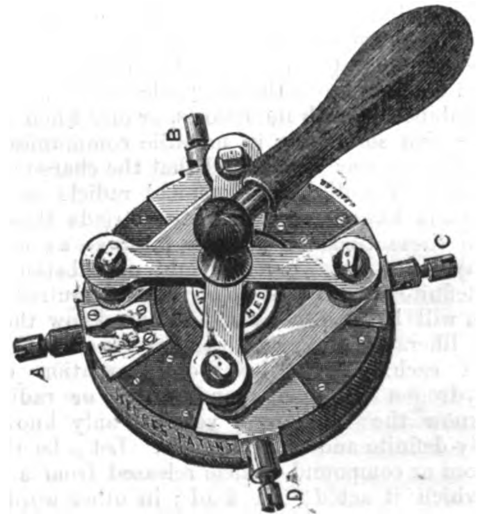

Fig. 3.

enter the lamp at B, passing from the positive terminal A through the contacts of the switch. By sliding the top contact on to B the connection with the positive terminal A is broken, and the current enters the line of lamps from the machine by means of the negative terminal C. The arrangement of these switches entirely does away with chance of setting fire to the wood block, which sometimes takes place with those where the contact piece simply slides off above the unprotected wood. They were exhibited at the Crystal Palace by the Electric Lighting Supply and Fitting Company, the sole makers.

ELECTRICAL ACCUMULATORS OR SECONDARY BATTERIES.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

(CONTINUED FROM PAGE 93.)

No. II.

A Planté and a Faure cell, though the process, and more especially the time, of formation is different, are, when formed, pretty much the same thing; and consist of two plates of lead, one coated with black peroxide of lead ($Pb\,O_2$), the other with a spongy material consisting of metallic lead in a fine state of division and more or less alloyed with hydrogen; both plates immersed in dilute sulphuric acid of about ordinary battery strength. Two plates in this condition must, as explained last week, give a current when connected by a wire, the positive current flowing along the wire from the peroxide coated plate—the + plate—to the spongy metallic — plate, and back through the liquid in the other direction; the spongy lead becoming gradually oxidised, and the peroxide reduced to some lower oxide, all the time the current lasts, *i.e.*, until the condition of the surfaces has become either temporarily or permanently the same. In order to bring the plates into the active condition they are first coated with oxide of lead, either electrically (by Planté) or mechanically (by Faure), which is then acted on by an electric current passed through the cell for some considerable time, the current being made to enter the liquid at the plate which is to be peroxidised, and to leave it at the plate which is to be reduced. Hence the former of these plates may be permanently labelled +, for when charging the cell the current enters at it, and when discharging the cell the current sets out from it. The other plate is similarly always —. There need, therefore, be no ambiguity about these terms. The + plate is always to be connected with the positive pole of the dynamo, whether the latter is supplying the current to the battery and charging it, or whether the dynamo is receiving the current from the battery and being driven by it.

Theory of Electro-chemical Decomposition.—It was stated last week that electricity was conducted through a liquid by means of two opposite processions of the constituent—dissociated—radicles of whatever substance in the liquid is undergoing decomposition, and that every such radicle possesses a certain definite charge of electricity which it carries with it and delivers up to the electrode, either when it is set free by combination with its fellows, or else when it is made to combine with something in metallic communication with the electrode. It was also stated that the charge of electricity possessed by a dissociated monad radicle is constant; and that diads have twice this charge, triads thrice, and so on. From these considerations it follows—as was proved by Faraday—that for a given weight of substance decomposed, a definite quantity of electricity is required; a quantity which will be known as soon as we know the number of atoms liberated, the electrical charge of each, and the weight of each. Let q be the dissociation charge of a free hydrogen or other monad atom or radicle. We do not know the value of q yet, we only know that it is perfectly definite and unchangeable. Let μ be the weight of any atom or compound radicle released from a combination in which it acted as a k-ad; in other words, let its active atomicity have been reduced by k, or let k be the number of bonds which have been broken in the act of making it a free radicle—whichever way of expressing it is preferred—then it is necessarily possessed of an electrical charge kq.

Let N be the number of such atoms delivered up to an electrode in any time, then in the same time a quantity of electricity $Q = N\,k\,q$ must have passed through the cell; and the weight of the substance liberated in the same time is $N\mu$—call this M. Then

$$\frac{M}{Q} = \frac{\mu}{k\,q}$$

Now, in the right hand side of this equation k is the only thing we know; we only know the relative weight of different atoms, not the absolute weight of any. Let h be the absolute weight of a hydrogen atom, and m the number ordinarily known in chemistry as "atomic weight," viz., the number which expresses the weight of any atom relatively to hydrogen, so that $\mu = m\ h$; then the above equation may be written

$$\frac{M}{Q} = \frac{m}{k} \cdot \frac{h}{q}$$

Now, though neither h nor q are yet known, their ratio has been determined by careful measurement, and it is 1·9505 in C. G. S. units; in other words, the electrical charge of a free hydrogen atom is 9505 times its weight in grammes. And the charge of any other radicle of atomic weight m and with k free bonds is $\frac{9505\,k}{m}$ times its weight in grammes.

If the weight of the substance be expressed in pounds, and the quantity of electricity concerned in its liberation or decomposition in ampere-hours—as for practical purposes is rather convenient—the above number 9505 becomes 12,020, or, with sufficient accuracy in ordinary cases, 12,000. So we will now repeat the above equation in an easy and practically useful form:—

$$\frac{\text{Weight of substance acted on in a single cell, in pounds}}{\text{Quantity of electricity passed through it, in ampere-hours}} = \frac{\text{ordinary "atomic weight" of the substance}}{\text{12,000 times the number of bonds released per atom of the substance.}}$$

Whether the "substance" is the constituent which is liberated at the positive or at the negative pole, or whether it is the original compound, which is not "liberated" at all but decomposed, matters nothing. The above statement is perfectly general and universally applicable. It applies also when it is recomposition that is going on instead of decomposition.

The expression "number of bonds released or joined per molecule" is not a happy one, but the phrase "change of valency" is no better, and the very simple meaning intended to be expressed is best conveyed by an example. Suppose $Cu\,SO_4$ is being decomposed; two bonds are released when Cu separates from SO_4, hence

$$\frac{\text{Weight of sulphate of copper decomposed}}{\text{Quantity of electricity passing through it}} = \frac{63{\cdot}5 + 32 + 64}{24{,}000}$$

But we might equally well write—

$$\frac{\text{Weight of copper deposited}}{\text{Quantity of E required}} = \frac{63{\cdot}5}{24{,}000}$$

Take as another example the decomposition of common dilute sulphuric acid, with copper electrodes say,

$$\frac{\text{Weight of hydrogen set free}}{\text{Quantity of E passed through cell}} = \frac{1}{12{,}000}$$

$$\frac{\text{Weight of sulphuric acid decomposed}}{\text{Quantity of E}} = \frac{98}{24{,}000}$$

$$\frac{\text{Weight of sulphate of copper formed at the expense of the oxygen electrode}}{\text{Quantity of E}} = \frac{159{\cdot}5}{24{,}000}.$$

Suppose nitrate of silver is the substance acted on. Here only one bond is released per molecule, so

$$\frac{\text{Weight of silver deposited}}{\text{Quantity of E}} = \frac{108}{12{,}000}$$

$$\frac{\text{Weight of nitrate of silver decomposed}}{\text{Quantity of electricity}} = \frac{170}{12{,}000}$$

Finally, suppose the substance acted on is Pb O, the protoxide of lead, then

$$\frac{\text{Weight of litharge oxidised to peroxide}}{\text{Quantity of E required.}} = \frac{223}{24{,}000}$$

* We reprint these excellent articles from the *Engineer*.

Digitized by Google

Weight of litharge reduced to metallic lead, the same.

Thus a current of one ampere is able to oxidise on one side of a Faure cell $\frac{223}{24,000}$ lb. of litharge per hour, provided there is no waste, nor any gas given off, and to reduce the same amount on the other side. Or every pound of litharge on either side of a Faure cell requires 108 ampere-hours for its reduction and oxidation.

If instead of one cell a number n are taken and arranged in series, and current sent through them, all the above action goes on in each cell, so of course the total decomposition will be n times as great.

No. III.

To understand fully the action going on in a Faure cell it is necessary to know something about the salts of lead, for at the present time lead seems by far the most suitable material for secondary batteries.

The protoxide of lead is called litharge, and is of a yellow or puce colour. Its constitution is Pb O, and its atomic weight, therefore, 223. The intermediate oxide is red lead, or minium, and its constitution appears to vary from $Pb_2\ O_3$ to $Pb_3\ O_4$; but it is most commonly the latter, and its atomic weight, therefore, 685. The peroxide, or black oxide, or heavy lead ore, is $Pb\ O_2$, atomic weight 239; and it differs from the two preceding oxides in being a conductor of electricity, just as the peroxide of manganese $Mn\ O_2$ is.

The sulphate of lead, $Pb\ SO_4$, is also important in the present connection. It is a dirty white non-conducting substance, slightly soluble in strong sulphuric acid, but quite unsoluble in dilute acid and in water. It will be formed, of course, as soon as red lead or litharge are put into dilute sulphuric acid; and unless there is an excess it may happen that all the acid gets used up in this way, leaving only water, in which case the liquid will cease to conduct. A Faure cell must, therefore, contain a considerable space for the acid liquid in addition to the space occupied by the plates and their coatings. But even then the strength of the dilute acid will become gradually weaker if a new Faure cell is allowed to stand for some time before a current is sent through it; and its resistance will accordingly be pretty high when you begin to charge. While the current is passing, however, the $Pb\ SO_4$ formed while standing will be gradually decomposed, the lead being either reduced or oxidised, and the acid being reformed; so that the resistance of the cell will gradually diminish for this reason. It will also diminish for two other reasons, one of which is that the liquid is warmed by the current, and the average number of dissociated atoms thereby increased; while the other is that the spongy lead formed on the — plate, and the peroxide formed on the + plate, are both conductors; and hence the acting surfaces of the plates are practically slowly advancing to meet each other all the time the current is charging the cell, and the layer of non-conducting oxides and sulphate is gradually diminishing in thickness. Hence the urgent necessity for the flannel or felt between the plates. For if ever in the process of charging, any portion of the peroxide were to reach across to a portion of the spongy lead, a bridge of metallic conduction would be completed, and the cell would be short circuited. It would be as reasonable to try and charge up a bit of copper wire as such a cell.

We perceived in the last article that a current of one ampere was able, in 108 hours, to oxidise a pound of litharge to peroxide on the positive plate of every cell through which it is passed, and to reduce a pound to metallic lead on the negative plate in the same time.

The oxidation of a pound of minium ($Pb_3\ O_4$) to the peroxide can be effected by a rather less quantity of electricity, namely, by $\frac{48,000}{685} = 70$ ampere hours; there being four bonds joined up when $Pb_3\ O_4$ is oxidised to $3\ (Pb\ O_2)$. But to reduce minium to metallic lead requires a greater quantity—eight bonds having to be loosed—namely, $\frac{96,000}{685} = 140$ ampere-hours. Hence, provided there is no waste and no gas given off, twice as much minium will be oxidised in each cell by a given current as is in the same time reduced. But with litharge the quantities oxidised and reduced are equal. When minium is used, therefore, either the coat of it on the + plate must be considerably thicker than the coat on the negative, or else the + plate itself must be expected to be eaten into somewhat before the reduction on the other plate is finished, and must be made of sufficient thickness to stand it.

Every pound of metallic lead thus oxidised to peroxide will require $\frac{48,000}{207} = 230$ ampere-hours of electricity.

If any gas is given off, every pound of hydrogen collected accounts for 12,000 ampere-hours; or, as a pound of hydrogen occupies about 180 cubic feet under ordinary circumstances, we may reckon the electricity necessary as 67 ampere-hours per cubic foot of hydrogen. If any free oxygen is detached, the electricity may be reckoned at the rate of 134 ampere-hours per cubic foot, or 1,500 ampere-hours per pound.

Now let us take a single Faure cell charged with minium, and pass through it a measured current of C amperes for an observed time of T hours. Let the gas evolved be collected, and found to consist of h cubic feet of hydrogen and g cubic feet of oxygen. Let the weight of minium reduced to metallic lead on the negative plate be called x, and the weight oxidised to peroxide on the positive plate be called y, both being expressed in pounds avoirdupois. Further, let z pounds of the + plate itself be oxidised to peroxide; let a small quantity, say u pounds, of hydrogen remain associated with the negative plate, either mechanically as bubbles, or as a sort of alloy; and let v be the weight of oxygen likewise liberated but unable to escape, or else used up in some indirect way. Then the following two equations render a full account of all that has gone on, as far as electrical laws can express it:

$$C\,T = 70\,y + 230\,z + 1,500\,v + 134\,g$$
$$C\,T = 140\,x + 12,000\,u + 67\,h$$

The quantity g is probably zero if a properly weak current has been used in charging. The quantities u and v will also probably be small;* and, therefore, perhaps, for practical purposes it may be sufficient to write.

$$C\,T = 70\,y + 230\,z$$
$$C\,T = 140\,x + 67\,h$$

Now h, the volume of gas evolved, can be easily collected and measured. There remain then the three unknown quantities $x\ y\ z$. The above two equations are, of course, not sufficient to determine them, but they show us the kind of relation which must exist between them, on the hypothesis that u and v are negligible. Especially we learn how much the + plate will have been attacked at any time after the whole of its minium layer has been reduced.

The most direct way of determining C T is to insert in the circuit some kind of voltameter, say a couple of large copper plates immersed in a solution of sulphate of copper; then by the time that one of the plates has gained, and the other lost, P pounds in weight, the quantity which has passed will be

$$C\,T = \frac{24,000}{63{\cdot}5}\,P = 377\,P \text{ ampere-hours.}$$

* They are multiplied by large coefficients though, and I am by no means sure how far it is practicable to neglect them. I believe the reduced lead is alloyed pretty strongly with hydrogen.

Electric Lights in Rhode Island.—An important Act passed the General Assembly which will seriously affect electric lighting and telegraph companies. Several Acts were introduced for the incorporation of electric light companies, but the committee to whom they were referred inserted a clause by which City and Town Councils may order poles and wires down after a formal notice of thirty days.—*Engineering News*, New York.

ECCENTRICITIES OF PATENT LAWS.

We have already commented at some length upon several nice technical points which were judicially settled in the Glasgow telephone case, but which, nevertheless, were not scientifically settled. There remain some other points, not so nice, perhaps, but far more curious, which the law has pronounced upon, but which nobody can regard as being equitably disposed of. Litigation has often been likened to a lottery; but litigation in respect to patents would seem to partake more of the nature of surprise packets, with the additional drawback that even if you have the luck to select the sweetstuffs containing a coveted gold ring, as likely as not the policeman steps in and condemns your prize and the whole proceeding as a technical breach of the law. We have heard of the Welsh jury who gave a verdict of not guilty, but don't do it again; it is reserved for judges in patent cases to inflict heavy penalties while pronouncing a verdict of acquittal.

This, we imagine, was the universal opinion of laymen who read the admirable summing up of the learned judge in the recent trial—that portion of it, we mean, relating to the infringement of Edison's patent. Everything was clear and logical throughout the whole length of this remarkable judgment—except the verdict. For a long time nobody could discover any connection between the two; but on careful search it became evident that Mr. Edison had been guilty of the grave offence of saying too much, or too little, in his specification, and that his patent was, consequently, invalid—at all events for the moment. We are not presuming to question the law, still less to criticise the judgment itself; we are only commenting on the eccentricity of the law, and the unenviable position of men like Mr. Justice Fry who have to administer it.

That a patent should be exposed to wholesale invasion because of a simple informality, in the which a patentee is usually at the mercy of his agent, is curious enough; but when we are told that the informality can be rectified, though the infringement cannot, the situation becomes ludicrous. Hunnings's transmitter is judicially a piracy; but as the thing pirated had no technical existence, the pirate was let off. What will be the status of the captured prize when the owner establishes his rights—if ever he succeed in doing so? And how about the prize-money—that is to say, costs?

But the oddities of the case do not end here. We have called Hunnings's patent an infringement of Edison's. The judge has said so; and technically, no doubt, he is right. But does anybody seriously believe that it is so in fact, either morally or scientifically? If Edison's lampblack is a tension regulator it is a very bad one, and even as such could not be called original; whilst if Hunnings's coke is a tension regulator it is original only in its absurdity. The essential value of both these devices was not in their regulating the current, but in the newly-discovered fact that currents could be regulated so as to convey an exact counterpart in miniature of human speech; and this discovery was not the discovery of either Mr. Edison or Mr. Hunnings. Any new form of incandescent filament can be patented, it is said; why not any new form of tension regulator, the generic tension regulator itself not being patentable?

But, leaving this recondite point for the lawyers, we are next struck by the comical fact that whereas the one claimant who is judicially, though not technically, successful in this suit has not been at all successful in the practical application of his invention, on the other hand the invention which is declared to be merely a colourable imitation has been eminently successful. The counterfeit is really of some use, the original is of next to none. The materials patented by Edison are discarded as practically worthless, and material identical with that patented by the defendent, but legally condemned in his hands, has been substituted. For the upholders of our patent laws as conducing to improvements this is a hard nut to crack. Either Mr. Hunnings has a right to his improvement, or the public have a right to it without Mr. Edison's leave.

But this does not exhaust the tale of anomalies. We have hinted that, in our opinion, lampblack was a mere makeshift, and not a very ingenious one, to modulate the current. Once know the effect of modulating it by the impact of sonorous waves, there are a hundred ways of producing the effect. Reis did not quite realise the conditions; we owe their discovery to Graham Bell. A later discovery revealed the fact that light contacts would act as well, or almost as well, as a tympan for translating vocal sound into corresponding electrical current. But this discovery was Professor Hughes's; and not that of either Edison or Hunnings. Whatever may be said of the transmitter claimed by the first-named of these two litigants, that contrived by the latter is plainly an adaptation of Hughes's microphone—is, in truth, a heap of microphones fortuitously encased. Yet the microphone is not a patented property! Thus we have the phenomena of one person who infringes an idea which is not patented

Digitized by Google

being sued for infringing a third person's idea—not because it is really his, but because he happens to have patented its application. If Professor Hughes had patented his microphone, the Hunnings transmitter might have been held to be an infringement of, though undoubtedly a serviceable improvement upon, it. But in any case Mr. Edison could not have sustained an action against Professor Hughes, nor, consequently, against Mr. Hunnings. The rights of patentees are, doubtless, very sacred; if only they could be strictly defined they would, probably, be inviolable. But, unfortunately, the patent laws do not—no patent laws ever can—rigidly define them. Much must be left to the chance of a lawsuit, to the accident of evidence, and the cleverness of professional patent agents. Your ring may be genuine gold, but if the experts say it is brass, brass to all intents and purposes for you it must remain; on the other hand, be it never so brazen, it will be as pure gold to you if only fortune and the law-courts favour. These are the ordinary risks of patentees we suppose, but they are exceedingly expensive; and, from the public point of view, it is, perhaps, not such a laughing matter that a best possible telephone is not to be had without paying not only the price of it, but the cost of all this litigation into the bargain.

CORRESPONDENCE.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I will leave personalities alone, as the special function of Mr. Johnstone, and would point out to that gentleman that he, by descending to them, weakens his authority as an experimenter.

Again I ask, what justification has Mr. Johnstone for concluding that, because a current proceeds from the outside of his jar, on the inside being charged, *therefore* "electricity is *matter* and it has passed *through* the glass?"

If I speak to him through a window, and though he by "experiment" prove that it is veritably my voice and none other, is he justified in concluding that *my voice is matter*, and has *passed through* the window pane?

If, by exercise of that force, known as "the will," *I will* my outstretched hand to open and shut, is "my will" *matter*, and has it passed *through* my arm?

Mr. Johnstone concludes again that I am evidently "an advocate of two electricities," and again errs in his conclusions. To my mind it is a confusion of terms to speak of two or even *one* electricity; and the line of argument I have taken up against Mr. Johnstone's theory should show him that in the word electricity I recognise only a figure of speech conveying the idea of an active agent producing certain effects which we call electrical; that all matter is in a statically electrical condition until that equilibrium is disturbed, when the phenomena of electrical action appear.

Quoth Mr. Johnstone, "Where does the current come from which passes from E to H?" I will put another—Where does the voice come from which reaches Mr. Johnstone's ear from my side of the window?

I am asked, "Why does flame F stand upright when the jar is fully charged?" I reply, because the current has ceased to flow, as Mr. Johnstone may demonstrate by touching the jar with an earth line, when the flame will bend down again, of course.

Does Mr. Johnstone think he can bottle up electricity with a paraffin plug? Can he expect to fully charge a jar using a point for a knob? He might as reasonably expect to empty a well by pumping into a leaky trough which returns its contents to the source.

The only argument adduced by Mr. Johnstone that strikes me as sounding fair is, "that different samples of glass produce different results, some even failing to retain a charge at all."

But it is only sound—why is the charge not retained? Because it is neutralised by reunion, through, or over the surface of the glass, which has conductivity, owing to imperfection of quality or age.

The glass of Mr. Johnstone's jar is non-conducting, so he must not appropriate this argument as an admission in his favour.—Yours, &c., D. HARBORD.

Redhill.

THE TELEPHONE CASE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the generally accurate report of my evidence in the case of the United Telephone Company *v.* Cox, Walker, and Co., given in your last number, there are some typographical errors which are obvious, and a few blunders on the part of the reporter which perhaps you will allow me to correct. I did not say "a make and break instrument can only transmit the speech," but "can only transmit the *pitch*." A little further on (top of the first column on p. 116), "plate transmitter" should be "Blake transmitter." The middle of the same column, "cocks in the centre of each horn-electrode" should be "corks," and "plates of glass bedded," &c., should be "plates of brass." In the end of the same paragraph, "shaping" should be "shaking," and the word "speaking" should be inserted after "the most beautiful."

The description of the transmitter referred to in the foregoing paragraph is made unintelligible by the transposition of a full stop from after the words "placed behind," where it should be, to the next line (twenty-eighth from the top of p. 116) between the words "thick" and "the coke," where it should not be.—Yours, &c., W. F. BARRETT.

RESISTANCE OF A VOLTAIC ARC.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would you or any of your readers be good enough to inform me what is the resistance (approximate) of a voltaic arc produced by fifty Grove pint cells, the carbons $\frac{1}{4}$in. in diameter, and each of them three or four inches long, and also the probable internal resistance of a battery of fifty cells, the platinums $2\frac{1}{8}$in. wide, nitric acid sp. gr. 1·4, the sulphuric solution one part acid (by measure) to 7 parts water?—Yours, &c., T. T. G.

SOME REMARKS ON ELECTRICITY AND PETROLEUM AS COMPETITORS OF COAL GAS.*

The remarks I have to offer to-day will be more of a practical than a scientific character. In the first place, I have tried as much as possible to divest myself of the prejudices on this subject which are common to gas men who have followed the business during the greater part of their lives. It is, perhaps, only natural that gas men should think that, what they have so long considered the very best agent for the purpose of illumination, cannot be superseded by anything new. At any rate they are not likely to become the first converts to new-fangled notions, but to be very conservative in their opinions, and reluctant to adopt the new faith in place of the old one. In fact, men who are worth their salt will not adopt it, until they have tried every means at their disposal to prove that their faith in the old ship is not without reason, and they will bring facts and arguments in support of it. To my mind, the most potent fact or test in this nineteenth century is that which will pay best, and is most convenient for public use. Men may talk and rant as much as they like, have as much newspaper puffing and

* A Paper read at the meeting of the Gas Institute last week by Mr. John Chew.

Digitized by Google

advertising as they can afford, but it will be only like a flash in the pan. If the thing does not pay it will not do.

It is with a feeling of this kind that I am induced to offer these remarks to-day. I do not wish to overvalue coal-gas as a lighting medium when put in competition with electricity or petroleum; nor, on the other hand, do I wish to undervalue the latter; to do so would be very unwise. I think, however, we should view the matter fairly all round, knowing as we all do, the early history of gas lighting, and the difficulties it had to encounter in making its way in public estimation three-quarters of a century ago. Most of us know so well what enormous sums of money were wasted before gas lighting began to pay, that we need not be surprised that in these days, when there is so much more wealth in the country, a portion of it should be freely spent in bringing electricity to greater perfection. Speaking of electricity, if you ask what it is, all I can say is that you cannot be told, any more than you learn what it is that gives the vital influence to the nervous system in human beings. We are sensible that it exists all through nature—in the air, in the earth, in water, and in human beings. We know that there are electric currents, and even electric storms or commotions, as there are storms of wind. In proof thereof I have only to point out to you how often you may read in the newspapers that a derangement has taken place in telegraphy, owing to the direction of the current being diverted by the prevalence of an electric storm in some particular district.

We know that in recent years great progress has been made in gathering, or, more properly speaking, diverting or generating electric currents, and using them for purposes of illumination, &c.; but we now safely say that we have almost reached the highest point of efficiency attainable in this department, as the generating machine gives out electromotive force to within 10 per cent. of the power applied. I need not here describe an electric depot, nor how the current is, so to speak, made to do work and yield light as the result. Those of you who visited the Crystal Palace Exhibition are sufficiently well familiar with the gas and steam engines and boilers used, and the results given out. A little farther on I may, however, give some particulars of the generating station fitted up by my department at Blackpool.

The various installations of electric lighting which have taken place in town and country up to the present time have been made with the conducting wires either overhead or underground. When wires are suspended in the air from poles or lamp-posts, they resemble telegraph lines, though they are much more dangerous should any happen to break while working. This fact alone will be detrimental to the adoption of all systems of overhead wires, and underground wires must of necessity take their place, inasmuch as you have then perfect immunity from danger to the public in the streets. The reason for employing overhead wires is not far to seek. It has been an endeavour to make the installation cost as little as possible. If the wires are to be laid underground, an expensive coating for insulation has to be resorted to; and to the cost of this has to be added the cost of the pipes and the laying them in crowded thoroughfares. The price of a bare conductor will be only one-half or one-third that of a properly insulated one prepared for being laid underground. Our first experience at Blackpool was with underground wires, to which the sea water percolated, damping and rotting the light covering which had been placed over them, and which would otherwise have been sufficient, until the whole of the current became lost, or, technically speaking, "made earth."

It is now nearly three years since we obtained power from Parliament to spend a sum of £4,500 on electric lighting, with a provision that the whole was to be repaid back, by means of a sinking fund, in ten years. We have accordingly spent £3,500 of the amount named, and have for this sum a generating depot about 1,300 yards from the farthest light, with two 16 horse-power (nominal) engines and boilers, with ten of Siemens's 6,000 candle machines, each of which absorbs about 4 horse-power. From this depot are supplied the nine electric lights, the whole of which are said to be equal to 54,000 candle-power when at their best. These are fixed about 60 feet high in clear glass lanterns, having reflectors, 4 feet in diameter, at distances varying from 180 to 400 yards. The wires are at present carried overhead, for the reasons before mentioned. You will, I am sure, excuse me if I say that I have not myself seen, in London or elsewhere, anything to equal this lighting in brilliancy and effect. As the lamps are fixed in the centre of the Esplanade fronting the Irish Sea, they are seen at distances ranging from 15 to 25 miles, and undoubtedly form a very charming attraction to our seaside watering-place. We have not adopted these lights with the object of saving on the cost of gas, but rather with a view of keeping our town in the front rank of watering-places. The Corporation are not at all sparing in the use of gas, for in our 20 miles of streets we have 650 gas lamps, including 30 or 40 of Bray's and Sugg's of from 60 to 100 candle-power. I will shortly give you the working charges on our electric plant, with a view to making some comparisons as to how the electric light may compete with gas; but the difficulty in which I find myself is to tell accurately the photometric power of the lights, as so many different estimates are made by different makers. Taking, for instance, the lighting of the City of London, and comparing the Brush and Siemens systems, the lamps of the former are put forth as being of 2,000 candle-power, and those of the latter as being of 300 to 400 candle only, yet, to an observer, it is very difficult to see which gives the best illumination, though the contrast ought to be as striking as it would be between a street lighted by ordinary gas lamps and one lighted by the improved lamps of 100 candle-power.

During the year ending March last we worked our lights for 25 weeks of seven nights each, or a total of 175 nights, being equal to 600 hours. The cost of this was as follows:—

	£	s.	d.
Wages	£179	15	0
Coke, water, and gas	63	19	2
Oil, waste, tallow	6	3	11
Carbons	51	0	3
Ground rent	15	0	0
Tradesmen's accounts for materials for the repairs of lanterns, engines, machines, wires, insulators, posts, and paint	125	11	9
Total	£441	10	1

The above charges are different from those of the previous year by about £20, arising from our having to renew two of the high poles; so that we may safely say that the working and maintenance charges are a fair average for the two years, or rather two seasons working. The total of the expenses, less interest, being £441 10s. 1d., and the number of hours burning 600, this is equal to 14s. 8d. per hour; to which must be added interest at, say 5 per cent., amounting to £175, or equal to 5s. 10d. per hour. As, however, only the same interest would be payable if the lights were burning a greater number of hours—or, for the purpose of comparison, say 1,800 hours, which is the number of hours our gas lamps are in use—this would then reduce the rate to 2s. per hour, instead of 6s.; therefore the total cost would be 16s. 8d. per hour for sustaining what is called 54,000-candle illuminating power.

The next point is to consider whether there is 54,000 candle-power, and to get an approximate idea of what illuminating power each light actually possesses. I lately made a test of one of the electric lights against one of Bray's 60-candle gas lamps, which happens to be situated at a convenient distance from and in direct line with the light, and the result was that the average illuminating power was about 3,000 candles, or at the rate of 750 candles per horse-power, which was as near as I could ascertain with the rough apparatus at my disposal. Owing to the colour of the light the ordinary disc photometer could not be used, and I had to arrange for throwing a direct shadow upon a white ground. The light from the arc is so variable at times, although it is scarcely perceptible to the ordinary eye, that it was with difficulty that I could tell for any length of time the exact position for the meeting point. I have no doubt, however, that if the electric light had been on the ground, and under control for the fine adjustment of the arc during the test, a much higher result

Digitized by Google

might have been attained; but this may be taken as a working test, though it is possible to get 1,500 candles per horse-power in experiment.

I will now put this result in comparison with coal gas, which in Blackpool is produced of from 18 to 20 candle-power, and sold at 3s. 3d. per 1,000 cubic feet; but if the Corporation were content with 5 per cent. interest only, it could be sold at 2s. 3d. per 1,000ft.; and seeing that I have put the electric light at this rate of interest, it is only fair that I should put gas at the same rate. This would work out as follows:—To produce gaslight of 27,000 candle-power, which will be that produced by the nine electric lights, would require say 27 gas lamps, each of 1,000 candle-power. These would consume 7,500 cubic feet of 18-candle gas per hour, which at 2s. 3d. per 1,000ft. would be equal to 16s. 10d. To this must be added the cost of cleaning, lighting, and repairs, at say 30s. per lamp for 1,800 hours, which on 27 lamps is equal to £40, or at the rate of 5s. 3d. each per hour; making a total of 17s. 3d. as the cost of gas against 16s. 8d. for electricity, or a difference in favour of electricity of 7d. per hour. You will see, then, that for large lights, such as those we use, electricity apparently would cost less; but it has the disadvantage of being a concentrated light, and cannot as yet be economically divided into small ones. A light of the power we use is too large for ordinary lighting, as you cannot obtain from it its full advantage.

To divide this light of 27,000 candle-power into incandescent lamps, so as to make them suitable for houses and streets, a very much larger outlay of capital would be required for plant to produce the same lights. If we were to use our own apparatus—that is to say, the engines and dynamo machines—as a generating station for the production of incandescent lights, we should have from the 40 horse-power developed, and the generating machines at the rate of ten 16-candle lights for each horse-power, equal to 400 lights for the whole of the total power of 6,400 candles, instead of the 27,000 we get from the arc lights. This is not one-fourth part of the amount of light we obtain from the arc system, taking the latter at half the amount stated by the makers of the appliances, and the incandescent light at the full value stated by them. What it would be if we had generating stations distributed about the town, and conducting wires laid in the streets, I could not even guess. It was recently given in evidence by Dr. Siemens, before the Parliamentary Committee on the Board of Trade Electric Lighting Bill, that to supply 2,000 horse-power value of light would require a capital of £100,000. This amount worked out at the usual rate of 10 lights per horse-power, each 16 candle-power, would give a total of 320,000 candles, being at the rate of 6s. 3d. per candle. However, Mr. Johnson, the agent of the Edison Company, gave 33,000 lights of 10 candle-power, or 330,000 candles, for £100,000, which will be found to work out to a little more than 6s. per candle. Applying the same figures to our own apparatus as above stated, the capital works out to 10s. 11d. per candle.

Certainly electric lighting seems very far from being within the range of practicability at present, notwithstanding all the advances it has made within the last three years. A great deal has been said about gas-engines being made the motive power for driving the generators, and about this being the most economic method of applying it. Perhaps it is; but those who have bought good gas-engines know that there is not much, if anything, gained in the outlay, in the first instance, between the cost of them and an engine and boiler worked by steam. The gain would be in superintendence. Who are the people likely to use the incandescent light in their houses? The most wealthy, to whom money is not an object. It will never do, however, to set up works to supply only the wealthy in a community. When the Electric Lighting Bill has passed through committee I trust the responsibility of maintaining a supply of gas will not be enforced by the Legislature. Where an electric light company competes with a gas company let them have a fair field, under the same conditions, and no favour; then the old doctrine of the survival of the fittest will put one or other into its proper place.

I am not surprised that the Brush Company and its offshoots declare large dividends, and that their shares command so great a premium. I do not see that they are doing much beyond acting as makers of a special class of machines in which they have a monopoly. As long as the public will buy their apparatus at present prices, this will continue. The district they light in London is the best and cheapest advertisement they could have. The "tall talk" of this company, and that of Hammond and Co., just floated, surpasses anything I have read out of America. If any one will read the speech delivered by Mr. Hammond at the Cannon Street Hotel, on the 18th of May, at a sort of statutory meeting of the Hammond Company, he will be treated to such a specimen of brag and bunkum that I should have thought no body of commercial men could have digested. People are investing their money now in these electric light companies as they have often done before in South American stocks, Turkish bonds, lead mines, and salted gold and silver mines. From the last return I have seen, from January to May 20, electric light companies have been registered with authorised capitals amounting to over £9,000,000 sterling. This certainly indicates that there is more capital in the market than can be employed in legitimate trade, and seeing that there is no fair opening that promises a profit, it must be recklessly employed to blow out a large number of bubble companies that will never exist anywhere but on paper and as a medium for share speculations.

Speaking of the electric light as it is, one would suppose that people think no improvement tending in the direction of reduced prices for gas is possible. I must differ largely from this opinion. If the capitals of so many companies and corporations can only be brought to bear a rate of interest that is now ruling the money market, it will not be one town alone that will supply gas at 1s. 9d. per 1,000 cubic feet, with 5 per cent. interest on capital expended, and nothing taken off the price to go in relief of rates, and new and improved apparatus erected at a less cost than formerly; and although great improvements may hereafter take place in the supply of electricity, there is plenty of room for it before it will be able at all to compete with coal gas. So far as it has gone it has benefited the suppliers of gas by calling into requisition a need for a greater quantity of light, and, as a result, more gas, and more capital at a low rate. I am willing to concede that many shareholders who have become possessed, by purchase or otherwise, of 10 per cent. stock, for which they have paid a price that will only yield 5 per cent.—particularly if it be in companies with inflated capitals and high-priced gas—are likely to suffer, as also will corporations who have bought too dearly be deceived in expecting to relieve the rates by their purchase; but we, as a body of gas engineers, are bound to do everything in our power to produce a cheap and good quality of gas suited for all the various uses to which it will be hereafter applied, and, in so doing, fear no competition from electricity, as it will stimulate us, by healthy competition, to push on to still greater improvements than any we have made in the past. When I undertook to write this paper I purposed saying something about petroleum as a competitor of coal gas. I think the subject worthy of some attention at our hands. There can be no doubt whatever that in many small towns in the country petroleum is a much more formidable competitor of coal gas than electricity, especially in the houses of the working classes. But perhaps I had better give you some particulars of my own experience in its use for street lighting purposes, seeing that during the whole of the past winter I used it for the supply of more than fifty lamps in a portion of our district in which we had not the power to supply gas. This part of our district was added to the borough about three years ago, and was quite rural in its character, and not likely to have fifty consumers for the next ten years to come; but we found that a particular portion of the district had been annexed by a small gas company some five miles away. There was nothing but farmhouses on the road for that distance, and the company had not laid any pipes up to that time, and what we considered a fair offer of compensation was made to them to surrender their right to supply gas, but they declined. Since then we have not been able to agree to any terms, and have, therefore, set up lamp-posts every fifty yards through

Digitized by Google

the whole of the village, fitting up the posts and lanterns. Several kinds of petroleum lamps were tested for the purpose, and ultimately I decided to recommend the Silber Light Company's street lamps. As I go on I will give you the figures as to the cost of this undertaking for lighting during the past winter; the period of the cost to which I am about to refer to is from October 30th to April 30th—six months. The lamps were lighted shortly after sunset, and put out at twelve o'clock at night, and left out altogether for five or six nights about the time of full moon each month. The total number of hours during which they were alight was 962. The illuminating power of each light was equal to 10 or 12 candles, and I may say the lamps have been very satisfactory to the people for whose benefit they were up. You must not suppose by this remark that I consider them equal to gas lamps; but on account of their being oil lamps they were placed closer together than gas lamps usually are. In small country villages, from 70 to 100 yards, or even more, is not an uncommon distance for gas lamps to be placed apart, even when 14 or 15 candle gas is supplied.

After the first month or two, when we had removed certain little defects here and there, I did not have anything like the trouble I had anticipated with the petroleum lamps. Too much or too little air getting access to the lanterns would sometimes make them smoke, and at other times cause them to be blown out. The result was that I found they required double the amount of labour and attendance in lighting, keeping clean, and trimming, that an ordinary gas lamp does; but having made up my mind that they should succeed, the cost of extra labour did not deter me from going on with them. After making the closest inquiry, I find that out of the 54 lamps we had in use, it was very seldom that there were more than two or three out, or even doing badly, on any one night. Had I not made this experiment myself, I should have doubted very much that they would have done so well as they did; but having now tried it, I feel sure that, whether it be on the score of expense or the quality of the light, it is a dangerous competitor with coal gas for street lighting in any small country village, where gas is both dear and of poor quality.

The details of the expenditure in connection with the petroleum lamps are as follow:—

Outlay in capital account for 54 posts, fitted with lanterns and Silber oil lamps complete	£156	8	0
Expenditure for cleaning, lighting, and repairing	49	7	2
Petroleum oil	22	6	11
Six months' interest on capital at 10 per cent ...	7	16	0
Total	£79	10	1

This works out pretty nearly to ·37d. per hour for each lamp. The oil I used was of different prices. At first I thought I would get the highest, "Water White" brand. This was 1s. 4d. per gallon for casks; but I found this to be no better than the quality I am now using. It is what is known as the "Royal Daylight" brand. For this I gave 11½d. per gallon, but it is now offering at very much less—in fact as low as 8d. per gallon for casks—and it may be bought retail at 3½d. per quart, or 1s. 2d. per gallon. The price, of course, varies with the season of the year; but I have given the highest and lowest prices at which I have bought.

In judging of oil as a competitor with gas, this broad fact meets you—that a good oil lamp of the best make (we give 11s. 6d. each for ours) will give a light, taken roughly, of 10 to 11 candle-power, and consume in 20 hours one quart of oil, costing 3½d. at the retail price, whereas 100 cubic feet of coal gas, costing 5d. at 4s. 2d. per 1,000 feet in country towns, will give a light for 20 hours of from 14 to 16 candle-power. I have given these latter figures of quality and price at perhaps a fair average in each case. I had not the means at my disposal for testing the exact photometrical value of the kind of oil lamp I use (the size and make being inconvenient for placing it in the bar photometer) except in a very rough way; but I tested it sufficiently near for practical purposes.

When we consider the foregoing facts, it is not to be wondered at that the workman and cottager use oil instead of gas, when it is brought like milk to his door, and retailed in the smallest quantities. He cares nothing about the slight smell it gives off, and the trouble of trimming his lamp is not of much account, when his hands are already soiled with his day's work. A good workman's lamp can be bought for 1s. 6d., and this is all he requires. Under these circumstances, he will not trouble the gas company much, and for myself I can safely say that I do not regret it; for the collection of accounts from this class of customers, the trouble of inspection, and removals from house to house, the turning off and on of the gas for every change of tenancy, the takings and repayments of deposits, with allowance of interest at 5 per cent. we are compelled to give, cause no end of trouble and expense, which is scarcely compensated for unless these consumers are charged a higher price for what they bring to the rent-roll.

Having now made all the remarks that occur to me on the subjects of my paper, and put them as briefly as I could before you, I leave them in your hands.

PHYSICAL SOCIETY.—June 17.

The Physical Society met in Oxford by invitation of the President, and, after luncheon, in the hall of Merton College, by kind permission of the Warden and Fellows. The health of the Society was proposed by the President, and responded to by Lord Rayleigh. The usual meeting was then held in the Clarendon Laboratory, Professor Clifton, president, in the chair.

Dr. W. H. Stone exhibited and described an electro-dynamometer specially designed for measuring the currents used in the medical applications of electricity. For this purpose a light suspended coil is an advantage, and Dr. Stone adopted aluminium, which, with equal conductivity to copper, weight for weight, is very much lighter than copper. No frame was used for the coil, which was tied up with silk and varnished, amber varnish, such as used by photographers, being recommended by the author for this and similar purposes as preferable to shellac. A bifilar suspension of the coil was adopted to give directive force to the coil, the threads being of silver gilt wire, drawn after gilding, and such as is used in making gold lace. It is preferable to platinum wire by reason of its lower resistance. Silver gilt wire, $\frac{1}{500}$in. in diameter, has a resistance of 9·8 ohms per metre; whereas platinum, of same dimensions, measures 62·2 ohms. Aluminium wire can be drawn as fine as copper. Some difficulty has hitherto been experienced in making contacts with it for electrical purposes, but Dr. Stone believes he has overcome them. The gilt wire makes a good contact with it. The specific heat of aluminium is high, and hence it is recommended by the author for resistance coils. The threads of the suspension were hung from two little brass springs, placed horizontally in line, and capable of being adjusted to and fro so as to widen the distance between the points of suspension when necessary.

Mr. Varley, Professor Perry, and others offered some remarks.

Mr. Bosanquet then described his application of the Faure accumulator charged by a dynamo-electric generator to the working of laboratory apparatus instead of the usual Grove or other battery. The net result of his experiments is that the accumulators charged for two hours have sufficient energy to keep the apparatus employed running for a week, and hence it is unnecessary for him, as heretofore, to put up thirty Grove cells each day.

Professor Perry observed that a well-made Faure cell having the minium laid on in a uniform coat does not loose its charge nor develop local action as is done by those accumulators in which the minium is put into holes in the plates.

Professor W. G. Adams then took the chair while Professor Clifton described some ingenious devices adopted by him in lecture experiments on electrostatics. These consisted of insulating glass stems, with glass cups to hold sulphuric acid formed on the stems; also a form of key which by rapidly-succeeding contacts brings the spot of light on the electrometer scale to rest without tedious swinging. He also described a form of lecture galvanometer, sine or tangent, which could be readily shown in all its working to a large class, and exhibited a simple and inexpensive apparatus for measuring the focal length of a lens in six different ways, according to what is known about the lens. The results showed that the apparatus was very accurate in its indications.

THE CRYSTAL PALACE EXHIBITION.

(CONTINUED FROM PAGE 114.)

Post Office Exhibits.

Between the double-needles is one of the same kind in principle, having a handsome Gothic case. It was made by W. Reid, mechanist, 25, University-street, London, and used at the House of Commons. The two-needle instruments required a pair of wires. The single needle, which follows in order, performs its functions with only one wire.

A large assortment of historical apparatus is here collected, old and new insulators, including Cooke's goose quill, used on the first *actual* telegraph line between Paddington and West Drayton in 1838, together with lightning protectors of various kinds. We then come to several kinds of batteries, amongst them being Varley's zinc-carbon *secondary* battery (1862), which was used at the central station (London) for distributing time signals. Specimens of Post Office submarine cables, a piece of the first cable, as well as a length of the first Atlantic cable are shown; as also a pretty model of a cable repairing ship, designed and skilfully made by Mr. W. R. Culley, of the Submarine Department, G.P.O.

Several instruments are working—the Wheatstone A B C (Fig. 6), single needle (Fig. 7), single or duplex ink-writers,

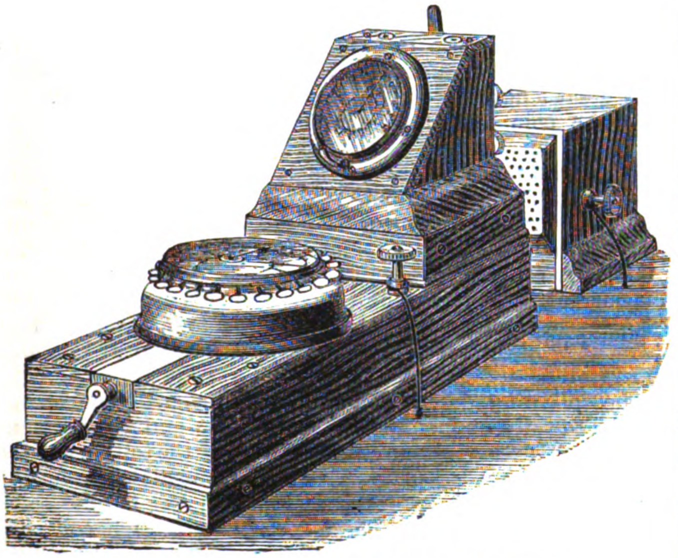

FIG. 6.—Wheatstone's A B C Telegraph Instrument.

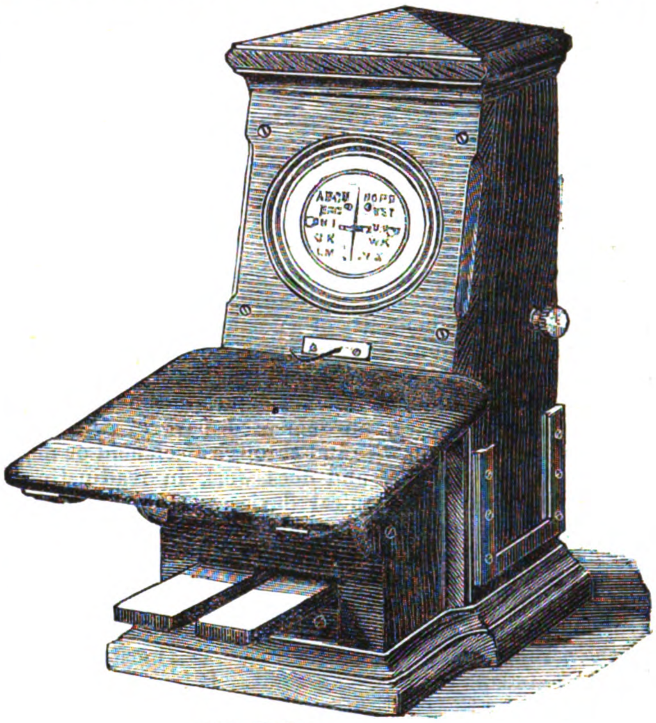
single current sounder, double-current sounder, duplex double-current sounder set, Wheatstone's automatic system, Kempe's water level indicator, Professor Hughes's induction balance, and a pneumatic system. These signalling instruments comprise visual, recording, or non-recording, and acoustic systems. Galvanic batteries supply the requisite electric force for all except the Wheatstone A B C, which has a magneto-electric generator. Here the sending operator turns a handle continuously, and rotates a piece of soft iron in front of and close to the poles of a strong horseshoe magnet, the arms of which are surrounded by fine copper wire covered with silk. The moving iron disturbs the normal condition of the magnetic field, and develops thereby electrical currents in the copper wire coils. These currents change their course through the wire alternately as the iron armature revolves. The alternate electro-magnetic effects in the receiving instrument propel a small tooth wheel fitted on the opposite end of an axis to that which bears a pointer in front of a dial bearing letters, figures, &c. The dial has 30 divisions, hence that number of currents is required for a full turn of the pointer. Four pulsations would cause the pointer to indicate D, ten J, and so on. A similar dial on the *sending* instrument, with keys for depression behind the letters, regulates and controls the outgoing currents. The instruments are so easy to manipulate that no special training is needed to send and receive a message slowly, hence they render good service in private firms and small post offices where skilled manipulators cannot be obtained. Other telegraphic instruments necessitate long experience before a thorough mastery of their use can be acquired. Indeed, when we state that from the central station at St. Martin's-le-Grand, *fifty thousand* ordinary telegrams are sent and received *daily*, besides *half a million* or more of Press words every night, it will be understood that a professional telegraph clerk has much to learn before he or she can attain dexterity of manipulation sufficient for the requirements of an important office. Every class of instrument has its particular sphere of usefulness, and the system employed upon any telegraph line depends upon the nature of the work to be done, the amount of business, the number of places to be united on one wire, the length, construction, and state of the telegraph line.

The single needle is most used when several localities com-

FIG. 7.—An ordinary Single Needle Instrument complete, for reading by sight.



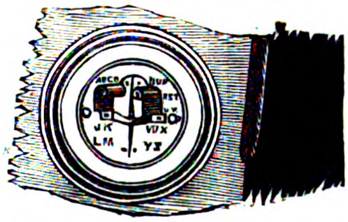


FIG. 7A.—A dial of the same, with resonant stops affixed, for reading by sound.

bined provide no more telegrams than suffice for one wire during office hours without causing delay. The Wheatstone automatic is invaluable for the despatch of newspaper intelligence, or a rush of work, as for example on the last Oaks day, when 57,441 messages (including 31,846 re-transmitted telegrams) were sent away from the Central Telegraph Station in London.

A brief description of the electrical principles of the systems of telegraphy above mentioned may not be unwelcome to some of our readers, and we therefore offer them a few simple explanatory remarks. Let us at the onset realise one fact, namely, that it is impossible to obtain electricity without an expenditure of energy. In the Wheatstone A B C no electricity would be developed unless the soft iron armature was made to revolve; the work done by the operator in turning the handle, or, in other words, the human energy expended, is, in fact, transformed into electrical energy. In the

Digitized by Google

galvanic battery we have chemical energy converted into electrical energy. Now, if we joined the poles of a battery together with a wire, we should cause a current of electricty to circulate through the battery and wire; we should establish an unbroken path, or what is called in telegraphy a *circuit*. Bend the wire into a ring over a sensitive mariner's compass, and the needle moves to one side. Change the bend of the wire relative to the poles of the battery, and instantly we find the deflection of the needle reverse of what it was before. Why? Because the *direction* of the current round the needle is altered. This is the basis of the Needle instrument (Fig. 7). A horizontal axis supports two needles, one a magnet, inside, encircled by coils of insulated fine copper wire, and the other merely an index needle outside to show the movements of the magnetic needle as it is influenced by the currents of electricity passing through the surrounding wire. Instead of twisting the battery wire as before, a mechanical arrangement consisting of two pedals (or a drop-handle) varies the direction of the current, and thus produces single or combined beats of the index needle against the ivory pegs (Fig. 7) or tin cylinders (Fig. 7A) forming the telegraph alphabet. When the tin cylinders are employed the receiving clerk can either read by sight or by sound—the latter is the quickest and best.

(TO BE CONTINUED.)

THE ANDRE ARC LAMP FOR STREET LIGHTING.

In most arc lamps the distance between the points of the positive and negative carbons is adjusted, from time to time, through the instrumentality of a portion of the main current passing along a shunt wire, the resistance of which is high compared with that of the arc and the main circuit. When the arc grows long, and the resistance in the main circuit consequently increases, an increased part of the current passes along the shunt wire and through a solenoid or magnet in some form or other, and does work in readjusting the carbons by some mechanical device. However well the lamp may be designed, it is evident that its whole success depends on the sensitiveness of the shunt current acting on the regulating apparatus. If the length of arc is not constantly readjusted, not to a fixed length, but to a length depending on the varying condition or position of the ends of the carbons at the time, the result is a most unpleasant hissing sound or a flickering light. It is, according to M. André, because the performance of actual work by the shunt current absorbs so much of its sensitiveness that this method of employing it appears to be defective. The shunt current is only a small part of the main current, and therefore incapable of exercising any great power upon the regulator, which is therefore a somewhat delicate machine.

In the André street lamp it has been attempted to greatly reduce if not altogether to do away with these defects in the regulating apparatus. The shunt current acts on a very sensitive apparatus, and has scarcely any mechanical work to do; it does little more than determine the time when the feed train is to be put in motion. This feed train is actuated by a larger current, capable of overcoming any small obstacles, and supplied at definite short intervals.

The shunt current passes round the magnets of the regulator, and when, owing to the increase in this current, these magnets become sufficiently powerful, a swinging armature is attracted very near to the poles, but so as not to come in actual contact with either of them. As this armature swings round it switches the feed current, which is supplied intermittently through a separate wire, into the feed magnets, so that, before passing on to the next lamp, this comparatively powerful current works the feed train and readjusts the carbons. This armature is balanced by a small adjustable counter-balance weight, so that its action always corresponds with a definite strength of shunt current, and consequently with a definite condition of the arc as regards length or resistance. When the feed current is not made to pass through the lamp by this regulator, it is practically passed on to the next lamp in the circuit, so that this apparatus is really an automatic switch, which determines whether the feed current, in its passage through each lamp, shall be utilised to work the feed magnets, or shall be sent on without doing any work to render assistance to some other lamp. The motive power of the feed apparatus is obtained from an electro-magnet, which by means of an armature drives a train consisting of a ratchet and ratchet wheel, a pinion, and a vertical rack in connection with the positive carbon. This arrangement of ratchet wheel, pinion, and rack admits of very small movements of the adjustable carbon, while the electro-magnet is so proportioned that only a small current is required to enable it to produce a very considerable force, capable of overcoming any unusual mechanical resistance in the feed mechanism within reasonable limits. The feed current in all cases, whether it is employed in feeding any particular lamp or not, passes through all the lamps on a circuit.

In this lamp, as in other systems, the carbons are in contact at first starting. When the main current enters the lamp, the whole of it passes through an electro-magnet, which by means of an armature and intermediate gearing raises a tilting ring, and along with it the upper or negative carbon. This carbon, being much shorter and lighter than the positive carbon, and the whole main current being the motive power, the action of this arc striker is very certain, and the negative carbon is kept in its raised position as long as the current continues to pass through the lamp. One other special feature about these lamps requires notice. They have hitherto been constructed to burn positive carbons of one metre in length. In order to avoid the excessive resistance that would ensue if the current had to pass through a very great length of carbon, roller contacts are introduced near the points of the longer or positive carbon through which the current reaches the arc with very small resistance. The low resistance of these lamps, very little in excess of that due to the arc, is to a great extent the result of the arrangement just described. By the use of these roller contacts, at an approximately constant distance from the arc, a practically constant resistance is offered to the passage of the current. A current of twelve amperes has been found to give satisfactory results with these lamps, and ten of them, at least, in series can be supplied by one H Gramme generator.

The following description and diagrams will enable our readers to fully understand the mechanism and arrangement of this lamp:—Figs. 1 and 1A show views of the top part of the lamp. On the base plate A, which is insulated from the lantern by ring B, is mounted a standard, C. On the same base is fixed a two-armed electro-magnet, D, each coil consisting of four layers of No. 12 insulated copper wire wound on a wrought iron core, $\frac{5}{8}$in. diameter and $2\frac{1}{2}$in. long. The resistance of the whole magnet amounts to about 0·06 ohms. An armature, E, is suspended over the poles of this magnet by means of a rod, the other end of which acts on a lever, F, pivoted on the upper end of the standard C. This lever F is attached by two straps to a tilting ring, G, which is thus lifted whenever the armature E is attracted to the poles of the magnet D. Through this ring slides a rod, H, the lower end of which forms the holder for the negative carbon. Through the centre of the baseplate A, but insulated from it, rises the upper part of a long brass tube, J, which contains the positive carbon, the carbon itself being held central by means of roller contacts K (Figs. 2 and 3). The action of this part of the lamp begins as soon as the main current is turned on. The points of the carbons being in contact, the current enters through the positive carbon-holder, and after passing through both carbons is communicated through the standard C to the magnet D, the armature E is attracted, the ring G is raised, carrying with it the negative carbon-holder H, and so the arc is struck. When the current is turned off the armature is released, the carbon-holder H slides through the ring G, and the negative carbon falls into contact with the positive carbon, ready for another start. The brass tube J (Fig. 3), the upper part of which rises through the baseplate A of the upper part of the lamp, is continued downwards till it reaches a box cover containing the feed apparatus and the regulator. The feed apparatus

Digitized by Google

(Figs. 4 and 5), consists of two A frames supporting a shaft, M, to which are fastened a ratchet wheel, N, and a pinion, O. In front of the two frames stands a pair of electro-magnets P, joined at the bottom by a breach-piece. Each coil consists of sixteen layers of No. 24 insulated copper wire, wound on a wrought iron core ½-inch diameter and 2 inches long, ture Q carries on its upper surface the ratchet S, gearing into the ratchet wheel N, and so drives the shaft M. The pinion O drives the long rack T, the top of which receives the lower end of the positive carbon, whilst the lower end is protected by a brass tube, U, fixed to the baseplate of the whole arrangement. A paul, W, prevents the ratchet wheel

and the resistance of the pair of coils in series is about 6 ohms. At the ends of the shaft M, and outside the frames L, are two arms working loosely on the shaft, and carrying with their free ends the armature Q, which is adjusted to its proper position by the spring on the pillar R. The armature from running backwards. The ends of the feed magnet coils P are connected to the regulator, which is described below.

The regulator (Figs. 4 to 6) consists of a channel-shaped brass frame, X, between the arms of which are fixed two coils,

Digitized by Google

Y, each containing 500 ohms of insulated copper wire, six mils. diameter, wound on a wrought iron core 5-16in. diameter and $2\frac{1}{8}$in. long, joined at the back end by a breech piece. The other end of each core passes through the front end of the frame X, and terminates in a pole-piece, Z, the inner surface being cylindrical, and described about the central axis of the pair of magnets. An armature, β, rigidly connected to a lever, γ, is pivoted about this same central axis, and is free to swing near the top pole-piece Z, which it never can touch, owing to their cylindrical shape. The lower end of the lever γ carries two platinum pins, δ and δ', which play between the ends of two screws, ϵ and ϵ', fixed to the frame X, but insulated from it, one of which is pointed with platinum, the other with an insulating material. The lever γ also carries a rod and an adjustable weight, by means of which any desired counterbalance can be given to the attraction between the magnets and the armature. The coils ζ are on a shunt from the main circuit. When the arc offers its proper resistance, the small amount of current passing through the shunt is insufficient to attract the armature γ in opposition to the resistance of the counterbalance weight ζ; but when the resistance of the arc increases, the proportion of current in the coils γ also increases, and the armature β is attracted. The feed current enters at the platinum pointed screw ϵ, whence a route, offering six ohms resistance, is always open to it through the feed magnets or to the next lamp. When the attraction of the magnets overcomes the momentum of the counterbalance weight ζ, the platinum pin β falls against screw ϵ', whose point is insulated, and the feed current has no other course except through the feed magnets. When, however, the weight ζ renders the attraction of the magnets upon the armature inoperative, the platinum pin δ rests against the platinum point screw ϵ, thereby opening a passage almost without resistance through the frame X on to the next lamp.

It is claimed as an important feature in these lamps that the feed circuit in no way robs the main circuit. It is taken off as a branch direct from the generating machine, and it is evident that the two circuits can be so proportioned that the momentary decrease of resistance to the passage of the total current, due to the throwing in of the feed circuit as an additional channel, shall cause an additional quantity of current to be generated in the machine exactly equivalent to that which passes along the feed circuit. Thus the intensity of the current in the main circuit is left unimpaired and constant.

The following, M. André states, are some of the principal features of the lamp:—

Current used	12 amperes.
Diameter of positive carbon	12 millimetres.
Diameter of negative carbon	18 millimetres.
Resistance of lamp when cold	0·1 ohm.
Resistance of lamp when lighted	2·0 ohms.
Resistance of arc	1·9 ohm.

Candle power (actual), about 1,000 candles.

BRUSH MIDLAND ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on the 16th instant, at the City Terminus Hotel, Mr. James Whitehead presiding.

The SECRETARY (Mr. H. N. Myers) read the notice convening the meeting and the minutes of the last meeting, which were confirmed.

The CHAIRMAN then stated that both of the meetings to be held on the occasion were of a formal character, the first being for the confirmation, or otherwise, of the resolutions passed at the last meeting. As he stated on that occasion, the alterations required to be made in their Articles of Association were required by the committee of the London Stock Exchange. They in no way adversely affected the value of their property—on the contrary, as they would facilitate their obtaining a settlement and quotation on the Stock Exchange, he was inclined to think, as their shares would then be more easily disposable, that the alterations would somewhat benefit their property. The directors and the solicitor quite concurred in the alterations.

The resolutions, which have been published in *The Electrician*, having been confirmed separately,

The CHAIRMAN said: The second meeting, as you are probably aware, is called to comply with the Act of Parliament, which is to the effect that a general meeting of the shareholders shall be held within four months of the allotment of the shares. The object of that, no doubt, is to give the directors an opportunity to state anything they may have to state as to the position of the company, and for any of the shareholders to make any inquiries they may think necessary as to the proceedings of the company during the time it has been in existence. I need hardly say that, having been in existence so short a time—only a few weeks—the whole of our time has been occupied in the organisation of your Company, I hope on such a basis as will lead to great success. While we have no doubt in our own minds with regard to the ultimate success of the Company, we cannot disguise from ourselves the fact that there are some difficulties—and I hope you will all realise that—to contend against in the establishment of a company, and especially of a company which is trying to introduce an entirely new system—I might almost say an entirely new principle. I may say, first, with regard to the work we have done, apart from organisation, that several overtures have been made to us with the view to our granting concessions; but while we shall be perfectly willing to grant concessions to sub-companies providing we can see our way clear to a fair and reasonable profit, we feel that there is an obligation imposed on us to see that those sub-companies are started in such a way as neither to discredit us nor be a failure in themselves. Seeing that we shall have an interest in the profits of the sub-companies—because that is the system generally adopted—it is our duty to see that we do not part with your property till we are perfectly satisfied that the boards of direction of the sub-companies will commend themselves to us, and satisfy us that they are likely to carry out the object we have in view—the carrying out of the electric system in the districts belonging to us—and that they will be able to return a fair and reasonable and adequate profit to the shareholders. We might have parted with several districts belonging to us—some odd counties, some groups of counties—but finding the conditions we required with regard to the character of the boards of direction were not complied with, we have felt it incumbent, not only in our own interests, but in the interests of the Brush Company, to decline the overtures made to us. Before I part from this subject I may say that many of you, being commercial men, are, no doubt, aware that many companies have been wrecked simply because they have not had proper boards of direction for their guidance, and we have been particularly anxious in our dealings with this matter to take care that our "children," were not only instructed, but that they should also have a fair start in life. There is one other point on which I should like to say a word—in regard to the question of price. One of the great difficulties in the establishment of a new system such as this is to acquire a sufficient amount of business at starting to enable the company, looking at all its ramifications and expenses, to realise a profit. It was so in the case of gas. I am old enough to remember when, in my district, gas was 10s. or 12s. 6d. per 1,000 cubic feet. That was only because the quantity used was not large enough to enable the gas company to make a sufficient profit, and so it will be for some time with these companies till electricity, as a system, has got into more active operation; but I am persuaded, as are also my colleagues, that whether it be twelve months hence, or two years hence, the electric system will be the illuminating power of the country, and that, in all human probability, those companies that have been started, as we think ours has been, on a fair and reasonable basis, will not only be successful in giving the public the electric light, but successful also in giving the shareholders an adequate return for the money placed in our care. On that point I may say it is very evident that the public are already aware of the great value attaching to electricity as a lighting power; but although that is clearly established a great many of the public do not realise the other advantages which belong to the electrical system. You must not forget that not only will you obtain the best light, and your curtains, decorations, and pictures be in no way injured by the new light, but the health of your family and your own health, which are so greatly jeopardised by the existing system, will, we hope and believe, be very much improved by the system we are now introducing. We must admit that the vitiation of the air by gas is very serious, and by the introduction of the electric light we shall have purer air in all our dwellings. There is one charge against us—I mean the Brush offshoots—namely, that we have paid too high a price for our concessions. I should like entirely to contest that point, so far as we of the Midland Company are concerned. You are probably aware that the total amount we paid for our concession was £43,750 for fourteen counties. This sum gives an average of £3,000 per county, and reckoning 10 per cent. per annum in order to provide for the interest on that amount and for the sinking fund, in order that the amount we have paid for our concession may be liquidated at the time our patents expire, a charge of not more than £300 per annum has to be made against those counties. To me that is a very satisfactory fact, and when we consider that we have important counties, with large populations, such as Cheshire, Leicestershire, Nottinghamshire, and Lincolnshire, I think you will admit that the position of this Company, as far as regards the price paid for the concession, is not a disadvantageous one.

A SHAREHOLDER inquired how the £43,750 was paid.

The CHAIRMAN: Partly in cash, partly in shares, and that, therefore, improves our position. If it should unfortunately happen, as we do not anticipate, that there is no dividend, there is no claim against the estate so far as that is concerned.

A SHAREHOLDER asked the proportions of the cash and shares paid.

The CHAIRMAN: £18,000 in shares, and the remainder in cash. I say that if the electric light system has anything in it, if it is to be the illuminating power of the future, and if the Brush system is, as we believe it to be, the very best of all the arc lights, then the amount we have paid for our concession, whatever other companies may have done, is not only not exorbitant, but is a very fair one indeed. It will be acknowledged by you that there has been a great scare recently in connection with electric light shares on the Stock Exchange, and that scare has possibly been helped forward more or less with the view of improving the interests of certain gentlemen who have very largely speculated in electric light shares. One of the systems adopted with a view to lower the value of the shares in the market is to issue circulars implying doubts as to the validity of the patents. That may suit the "bears," but I presume it does not suit the interests of the shareholders assembled today. We have no doubt, as far as we are concerned, as to the validity of the patents we have bought on your behalf for the Midland district, and if

Digitized by Google

we had any we are amply covered by a guarantee from the Brush Company, and being satisfied that we have valid patents to work upon, and being satisfied that we have the best of all the electrical systems, we hope, by energy, pluck, perseverance, and economy, perhaps assisted by what little judgment we may be able to bring to bear on your behalf, at no distant day to give you an adequate return on the capital you have confided to our care.

A SHAREHOLDER asked if there were no further payments to be made beyond the £43,750.

The CHAIRMAN: Nothing whatever. The £43,750 is the absolute total cost of the concessions. All profits made will be for the shareholders, except that portion that goes to the directors, who are to receive £1,000 a year. We only come in for additional remuneration when 10 per cent. has been paid to the shareholders. I think you will see at any rate that the shareholders are on the best possible footing. In answer to other questions, he added: We have granted no sub-concessions, because the conditions we have imposed, more particularly with regard to the character of the boards, have not been come up to. In answer to a shareholder, the Chairman said: Before our concessions were granted to us, Mr. Hammond had acquired certain rights, and had obtained permission from the Brush Company to install any lights he liked, at his own risk, in any part of the country. He has acted on that permission, but immediately this Company comes into operation Mr. Hammond's rights in our districts cease, and he has no claim on us in any shape or form. We are entitled by our agreement with the Brush Company to have the benefit of all further improvements that may be made by them.

On the motion of Mr. MARTIN, a vote of thanks was passed to the chairman and directors. In reply,

The CHAIRMAN said: We are much obliged to you. I can assure you that my heart is in the cause, and if I fail, and my colleagues fail, you may rely on one thing—that it will be because circumstances have beaten us, and circumstances only. I may mention that, although we have been in existence so short a time, we have successfully lighted up the Boston Docks and the Market Hall of Chester, and that our system is already in very active operation in Nottingham.

The proceedings then terminated.

SOUTH AFRICAN BRUSH ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary meeting of this Company was held at the City Terminus Hotel, on the 19th inst., under the presidency of Lieut.-Colonel George Coxon, to consider a resolution substituting for Article 71 of the Company's Articles of Association another clause similarly numbered. The article as altered defined the circumstances which would render necessary the vacating of the office of director, and set out certain conditions which would have to be complied with in case of any director being concerned in the profits of any contract or transaction with the Company.

The SECRETARY (Mr. Thomas J. Seel) having read the notice convening the meeting,

The CHAIRMAN stated that it had been convened solely for the purpose of complying with the requisition and instructions of the committee of the Stock Exchange with regard to altering the article referred to. He moved a resolution for authorising the alteration.

Mr. I. S. GORDON seconded the motion, which was carried.

The CHAIRMAN stated that he had nothing to tell them concerning their affairs on the present occasion. The meeting for confirming the resolution would be held in about fourteen days, and on that occasion they would hold their statutory meeting also. He expressed his readiness to give any information which might be asked for. Replying to questions, he added that the Company had been started on the basis of a concession of Messrs. Blaine and Macdonald for the Brush patents for the Cape of Good Hope, and the purchase made of them was for the concession and the whole of the plant, &c., which the firm had acquired. Mr. Atkinson, one of the members of the board, was a partner of Messrs. Blaine and Macdonald, but he did not join the board until the purchase had been completed. They were, by the alteration which had been proposed in the 71st of their Articles of Association, removing the one object which had been raised against their having a quotation. They would not be able to obtain a quotation until the resolution had been confirmed, nor could he say how soon it would be afterwards before a quotation would be granted.

Mr. SHORROCK asked how the contract stood with the Kimberley Corporation.

The CHAIRMAN, in reply, stated that on the 11th of May last, which was the day, or the day before, the Company was formed, Messrs. Blaine and Macdonald received a telegram from Mr. Donald Macdonald, their managing agent, to the following effect:—"Have made a contract for Kimberley." It appeared that some difficulties had been raised there. He (the chairman) believed that there was a great deal of opposition when the matter came to be submitted to the ratepayers, and at the time the telegram was received the agitation was going on. No doubt they had heard, as had been rumoured, that money had been subscribed in Kimberley to raise an opposition and to take legal measures to test the validity of the poll of the ratepayers, which took place subsequently, on the subject of lighting the town, and in which the question of lighting was carried by a majority of twenty-one. He was, however, happy to tell them that about ten days ago—or three weeks subsequent to the time the report was spread about that the matter was to be opposed—they received a telegram again from Mr. Macdonald asking them to wire out an authority for the Kimberley agent of Messrs. Blaine and Macdonald to sign in the name of the Company the contract with the mayor. They might, therefore, take it for granted that the contract entered into between the Mayor of Kimberley, representing the corporation of the place, and the South African Brush Company had been signed, and that the Company was now in the position of holding the contract for lighting Kimberley for two years. There could be no question about it. They had received no information that there had been any hitch, nor could he see any reason for there being any. On receipt of this telegram they sent out (they had been already shipped) two machines, one a 16-light machine for Kimberley (making with the one previously there thirty-two lights), and another similar machine for disposal by their manager in any way he thought proper, as they had thought it advisable that he should have at hand, and for immediate use, plant and machinery for taking advantage of any opportunity which might open for extending the operations of the Company.

Mr. SHORROCK inquired the terms which had been arranged for lighting the town of Kimberley.

Mr. ATKINSON stated that some time ago the agent submitted terms to the Kimberley Corporation. These terms were afterwards taken into consideration, and were submitted to a meeting, which was adjourned from time to time, but the final meeting took place on the 10th of May, and a telegram was received to the effect that the contract had been accepted, but nothing more. Whether the terms had been modified to some extent in the contract was unknown, and would be until they got the contract over.

A SHAREHOLDER asked whether it was not stated in the prospectus that a town at the Cape was lighted up.

Mr. ATKINSON replied in the affirmative. The town referred to was Kimberley, and it was lighted for weeks before, but a contract had not been accepted.

The SHAREHOLDER thought that the statement was misleading.

The CHAIRMAN held that it was not misleading. An arrangement had been made with the authorities at Kimberley to light the town. That was known for months before, and the town was lighted as an experiment, but on the 10th of May a contract was made.

Mr. ATKINSON, in reply to a further question, thought it would be unwise at a public meeting to mention the price of the contract. That would be the way to cause competition. The information might be obtained by the shareholders at the offices.

The CHAIRMAN observed that before long they would, he hoped, be able to give the fullest information as to the Company. On the day the Company was formed they wired to Mr. Donald Macdonald to return home, and he was now returning, but until he arrived they could not give any conclusive information at such an early meeting as this in their history.

The proceedings then terminated with a vote of thanks to the chairman.

RECENT INVENTIONS.

ABSTRACTS OF SPECIFICATIONS.

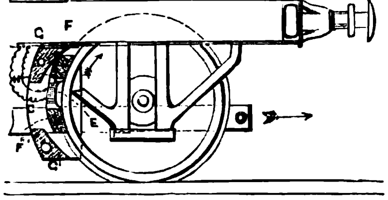
2807. Improvements in Telegraph Cables and other Conductors, *A. C. Ranyard, London, and J. A. Fleming, Cambridge.—27th June*, 1881.—(*Not proceeded with.*) 2*d*.

This consists in using manilla or other rope fibre in combination with "paraffine butter"—that is, a composition of paraffine mixed together at different boiling points, so as to render it always soft—as a covering for the wires of a cable

3464. An Electric Brake, *S. von Sawiczeski, Paris.—10th August*, 1881. 6*d*.

The figure represents the brake block in action. The electro-magnets E are enclosed in the box formed by the sheet iron C^1, suspended by spiral spring. The wedging of the brake blocks is produced against the wooden or metal pieces F F^1. Each electro-magnet has two brake blocks of special form, one upper and one lower, and are intended one for forward and the other for back-

3464



ward running. The action is as follows:—An electric generator in the train is connected by wires and commutators with the carriages and electro-magnets, so that the driver or guard may send a current acting on the electro-magnets, causing their instantaneous adhesion to the wheels, which then act as armatures. The impulsive force of the wheel carries the brake blocks in the form of wedges round into between the abutments G and G^1 and the wheel, which will cause a wedging action of a strength proportional to the current and the speed of the train.

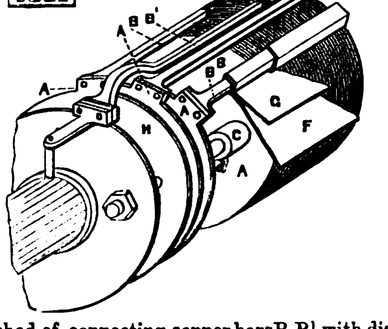
3635. Improvements in the Production of the Electric Light, *T. Tubini, London.—20th August*, 1881.—(*Not proceeded with*). 2d.

The inventor makes the carbons of an arc lamp hollow, and causes gas or oil yielding carbonic atoms to pass through them, thereby augmenting the light, &c.

3932. Improvements in Dynamo and Magneto Electric Machines, *P. Jensen, London.—10th September*, 1881.—(*A communication from T. A. Edison, Menlo Park, N.J.*) 6*d*.

This relates to improvements on patent No. 1240, dated March 21, 1881, which consists in the

3932

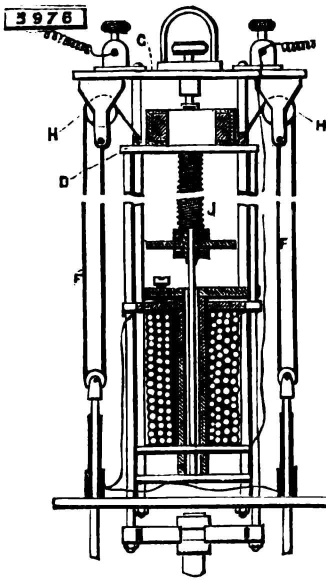


method of connecting copper bars B B^1 with discs by means of ears, A. The ears being now widened so as to close up the spaces between them. Bars B also extend straight to ears A, whilst B^1 are curved over the first line of ears to ears H of the second line. The contacts between the ears and the bars are plated with gold and silver. For commutator connections, rods having nearly the same conducting area as the bars are used; these contacts are also plated. To place the copper discs outside the field of force, the thimbles C separate them from the core as shown. The copper discs have double bevelled edges, forming angular spaces into which the projecting edges of the paper sheets used to insulate the copper discs are pressed to prevent electrical creeping between their edges. The copper bars are insulated by F parchment paper and G mica. An apparatus for driving a constant current of air through the armature is also described.

3976. Improvements in Elecric Arc Lamps, *P. Jensen, London.—14th September*, 1881.—(*A communication from A. J. B. Cance, Paris.*) 6*d*.

This is a continuous current lamp, though it can be converted into one for alternate currents. The lower carbon is regulated by the pulleys and cords shown. One end of cord F is fastened to plate G, having a hook for suspending the lamp, and the other end passes round pulley H, fixed to the base plate, and is fixed to upper cross bar

3976

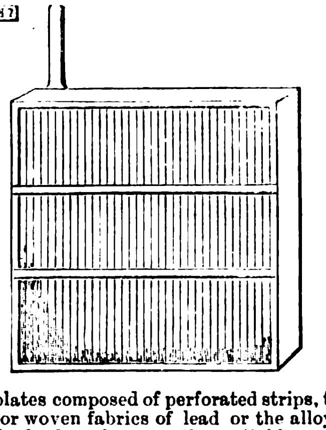


D, uniting side rods of upper carbon holder. Cross bar D forms a movable weight, and has a receptacle for shot. D constantly tends to descend, and thus causes screw J to turn, so that the lower carbon is pulled up by cords F, while the upper carbon, by the turning of screw J is made to descend. The electro-magnet and solenoid core shown are placed in the lamp circuit, and serve to start the arc and regulate it also.

3987. Secondary Batteries or Magazines of Electricity, *J. S. Sellon, Hatton-garden.—15th September*, 1881. 6*d*.

The claims are, first, the use of supports to carry the spongy lead or other material, composed of alloys of lead with antimony; secondly, the

3987



use of plates composed of perforated strips, tubes, pieces, or woven fabrics of lead or the alloy supported by lead, carbon, or other suitable material. One form is shown in the figure.

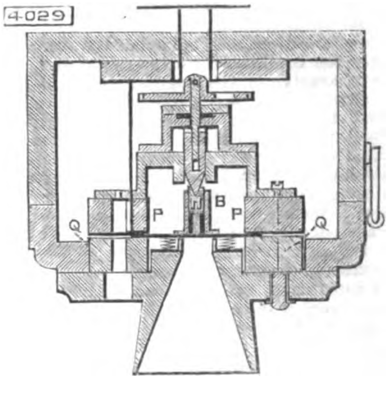
3519. Improvements in Means or Apparatus Employed in Lighting Gas by Electricity, *B. J. B. Mills, London.—13th August*, 1881.—(*A communication from L. A. W. Desruelles and G. J. A. Bourdoncle, Paris.*)—(*Not proceeded with.*) 2*d*.

The lighting of the gas is effected by a carrier of wood, in which is mounted a platinum coil heated to incandescence by an electric current. The carrier and coil are made to traverse the orifices of the gas burners.

4029. A New Construction of Telephone Transmitter, *S. Pitt, Sutton, Surrey.—19th September*, 1881.—(*A communication from H. Machalski, Lemberg, Austria.*) 6*d*.

This relates to a battery telephone in which graphite in a powdered state is used. The construction is as follows:—The vibrating plate is made of a thin sheet of iron or other similar metal, in the centre of which is attached by a gum a small tube B of elastic gum; within this is a second small tube, filled with pure pulverised graphite moderately compressed. The tube is closed by a metallic plug, the diameter of which

4029

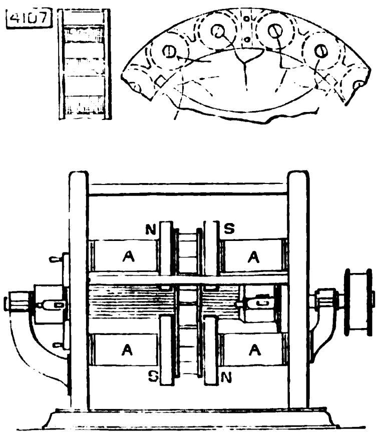


enlarges as it enters the tube, as its upper end is a conical hollow. Its base is also cylindrical, and contains a cylindrical cavity; upon this reduced end a small piece of elastic gum tube is applied, having the same height and exterior diameter equal to that of the plug. The plate with these accessories is placed between two rings P and Q. Between the plate and one of the rings a very thin conducting wire is placed, the other end of which goes to the holder. The figure will explain the arrangement of the apparatus.

4107. An Improved Dynamo-electric Machine, *F. E. Fahrig, Southampton.—23rd September*, 1881. 6*d*.

This relates to a continuous current machine, the coils of whose armature can be removed at will. Fig. 1 is a side elevation. The magnetic field is composed of magnets A. To the poles of each two upper and two lower magnets are attached by means of countersunk screws received in holes tapped in the cores, heavy semicircular

4107



pole pieces, N S S N, of malleable cast iron, which letters indicate their polarity. The armature, Fig. 2, consists of a number of transverse coils arranged round and parallel to the shaft, these being held in holes in pairs of segment-shaped plates, of which the annular frame of armature is built up. The coils are connected by wires each with a metal strip of the collectors.

2930. Improvements in Electric Lamps, *E. P. Ward.—5th July*, 1881. 2*d*.

This relates to incandescent lamps. The inventor substitutes iron or steel wires for the ordinary platinum connections with the carbon by enclosing each wire in an envelope of glass; the two envelopes thus formed are then connected by fusion at a suitable distance from the end. They are then united to the glass stem of the bulb by fusion.

Digitized by Google

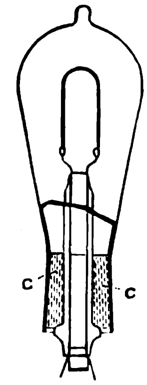
2833. Improvements in Incandescent Lamps, &c., *G. G. André, Dorking, and E. Easton, Westminster.—28th June,* 1881.—*(Not proceeded with.)* 2*d.*

The inventors use vegetable substances, such as rushes, grass stems, &c., for the carbons, and stretch them between two metallic conductors in a straight line, instead of the curved or horseshoe form usually adopted.

4174. Improveents in Electric Lamps and the Manufacture thereof, *E. G. Brewer, London.—27th September,* 1881.—*(A communication from T. A. Edison, Menlo Park, New Jersey, U.S.)* 8*d.*

Part of this invention refers to a cheaper method of providing the neck of incandescent lamps with the collar for attaching the lamp to its socket support. This is done by dropping the metal rings of the collar into a mould, wires being first soldered to the inner surface of such rings, which are arranged to project upwards on opposite sides of the mould. The wires of the lamp are bent up in opposite sides of its neck, and the lamp is dropped into the centre of the mould and held upright there. The wire ends of lamp and

4174

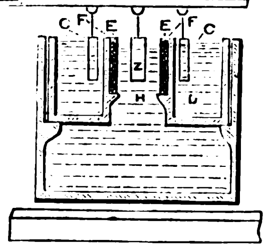


collar rings are twisted together and turned down into the mould, which is then filled with plaster of Paris and allowed to harden. Another portion of the invention refers to the construction of a lamp which can be taken to pieces when the carbon is destroyed, and all parts used again, except the carbon. The figure shows such a lamp. The glass globe is made to taper out at bottom. C is a tapering rubber stopper which has a tendency to be pressed into the globe by the atmospheric pressure, and which therefore holds the wire support tight. The methods adopted for electroplating the union of the carbon and wires are also described with other improvements.

4309. Improvements in Galvanic or Electric Batteries, *F. Wirth, Franfort-on-the-Main.—4th October,* 1881.—*(A communication from Dr. J. Stebbins, New York.)* 6*d.*

The object of the invention is to produce a battery of great constancy and easy regulation. The form thereof is shown in the figure. The bottom of H forms a non-porous reservoir. E E are porous walls of the upper compartments; F F

4309



non-porous material which can be adjusted to permit as much action as required to take place through E E. The letters D D represent non-porous cups, through the bottom of which is an opening Z to represent the zinc plate in dilute sulphuric acid, C C being carbon plates in a solution of bichromate of potassium.

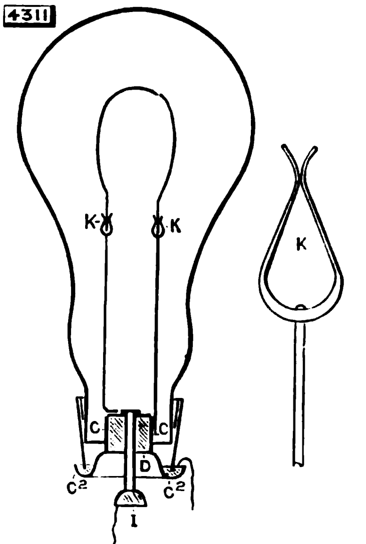
2823. Secondary Batteries, *A. P. Laurie, Edinburgh.—28th June,* 1881.—*(Not proceeded with).* 2*d.*

This relates to the use of zinc and carbon electrodes in a solution of iodide of zinc.

4311. Improvements in Electric Lamps, *J. H. Johnson.—4th October,* 1881.—*(A communication from C. A. Faure, Paris.)* 6*d.*

This relates to incandescent lamps. The inventor fixes a metallic socket to the stem of the glass globe, by fusing said stem to the inside of the socket, or by electro-plating the stem, then turning the socket and soldering the latter on to the electro-plated deposit. The carbon holder consists of a metal tube, C, closed by glass plug, D, the tube being splayed out into trough C^2, so

4311

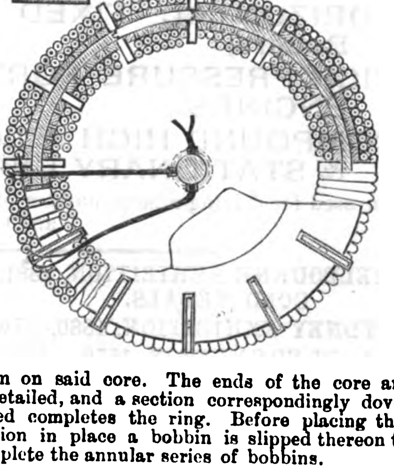


as to contain a metal which fuses at a low temperature, to receive the outer edge of the socket so as to make an air-tight joint, the object being to enable the carbon holder and the carbon to be withdrawn by simply fusing the metal so as to unsolder the parts. The carbon holder C and socket form one conductor, and tube I forms the other. The carbon is secured between two spring clips, K, of platinum. The inventor makes his carbons of thin strips of graphite or carbon, which are heated and bent to shape required.

255,137. Armature for Dynamo-Electric Machines, *George H. Brown, New York, N.Y., assignor to Charles A. Cheever, same place.—Filed November 14th,* 1881.

Brief.—The core of the armature has a section cut out, leaving a space, through which the separately-wound bobbins may be slipped to place

255,137



them on said core. The ends of the core are dovetailed, and a section correspondingly dovetailed completes the ring. Before placing this section in place a bobbin is slipped thereon to complete the annular series of bobbins.

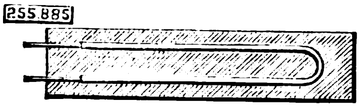
4420. Improvements Relating to Telephone atd Telegraphic Apparatus and Circuits, *S. Pitt, Sutton.—11th October,* 1881.—*(A communication from W. R. Patterson and C. E. Scribner, Chicago, U.S.A.)* 6*d.*

Part of this invention refers to an improvement whereby a central office manager can regulate at will the number of subscribers to be taken care of by a single attendant, and also a method of notifying the latter of a call when he is not listening at his telephone. By this invention the subscribers' wires are grouped at the central office to a common wire which connects to a listening operator's telephone and thence to ground, and the terminals of subscribers' individual wires are connected through call bells at subscribers' offices, and thence to a common wire, the said wire serving to group the outer ends of the telephone wires together. Each subscriber is thus provided with two circuits—first, his individual telephone; second, the lines of his group that happen to be connected with the common line at their outer ends when he connects with the said common line. Another improvement consists in connecting the calling battery with a point near the lever of each spring jack, and so constructing the plug that the switchman may by means of it connect any subscribers' line with a contact point connecting with the calling battery, and thus signal the subscriber. The invention also refers to improvements in telephone cables, whereby induction is neutralised.

255,885. Thermo-electric Battery, *Andrew Patterson, Idelwood, Pa.—Filed January 9th,* 1882.

Claim.—(1). The combination of the members of a thermo-electric couple with a mass of refractory insulating materials in which they are em-

255,885

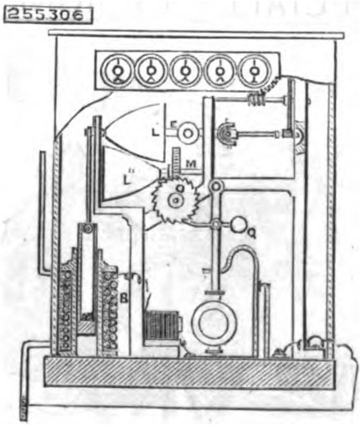


bedded, whereby fusible or oxidable materials may be used for the couple without injury from fusion or oxidation, substantially as described and set forth.

255,306. Electric Meter, *Hiram S. Maxim, Brooklyn, assignor to the United States Electric Lighting Compang, New York, N.Y.—Filed July 20th,* 1881.

Claim.—(1) In an electric meter the combination with the axially-movable core of the magnet B, of the universally-jointed shaft E, connected thereto by an intermediate link, and almost connected by intermediate gears with a registering apparatus, and carrying the conoid L, arranged to rock longitudinally upon the conoid L'', mounted upon a shaft journalled in fixed bearings and rotated by armature mechanism, substantially as described. (2) In an electric meter, the combination, with a registering apparatus, of a conoid, L, mounted upon a universally-jointed shaft in gear with said registering apparatus, a conoid-L'', mounted upon a shaft rotating in fixed bear, ings and supporting the first-named conoid upon

255306



its surface, suitable devices for varying the point of contact between said conoids by the influence of an electric current over the main line, and automatic mechanism for rotating said conoid L'' under the influence of a current derived from said main line, substantially as described. (3) The combination, with the registering apparatus and the electro-magnet B, arranged for connection with a main line, and provided with an axially-movable armature, of the universally-jointed oscillating shaft E, in connection with said apparatus and carrying the conoid L, a link connecting said shaft with said armature, the conoid L'', mounted upon shaft M, carrying a worm wheel, the ratchet wheel O, fixed upon a shaft carrying a worm meshing with said wheel, an electro-magnet in a circuit derived from the main line, a pendulum adapted to be oscillated thereby and provided with a pawl, Q, substantially as described,

THE EXCHANGE TELEGRAPH COMPANY, LIMITED.

Head Offices—17 & 18, Cornhill, E.C.; Stock Exchange, E.C.; 27, Regent Street, W.

Incorporated the 28th March, 1872, under the Companies Acts of 1862 and 1867, and by Special License from H.M. Postmaster-General.

This Company will undertake to supply recording instruments, telegraphically connected with the Stock Exchange, by the aid of which Subscribers, at their respective offices, may be kept continuously advised throughout the day of the constantly occurring market fluctuations in stocks and shares.

Instruments are placed in the offices of Subscribers and kept in order by the Company, free of every expense but that of rent, and inspectors visit them daily to supply ink and paper.

Terms: £50 per annum, payable quarterly in advance.

Applications for instruments to be made to the Secretary at the above address.

Not having any springs or clockwork to wind up or to depend on, these instruments are acknowledged by those familiar with the system of telegraphy to be the only instruments yet invented that are capable of doing the work required of them continuously for a lengthened period, as evidenced by the fact that the Gold and Stock Company of New York, having the monopoly of this kind of business in the States, and which owns all the patents of the day of any value, has, after due trial, discarded all others.

The Company is prepared to treat with provincial Companies requiring instruments for the delivery of news for either single or double wire systems under the Company's patents, whereby from central stations identical information can be simultaneously delivered to any number of recipients by automatic, self-adjusting, printing instruments requiring no local batteries, no winding up, and no knowledge of telegraphy on the part of the receiver, the printing being in bold roman type, and the propulsion of the paper being effected by the electricity supplied from the Central Office.

The instruments supplied by the Company can be had to work either on single or double wires, and to print either on a slip or tape of paper, as has hitherto been the custom, or on a broad band of paper in column form.

The system has been in use by the Exchange Telegraph Company (Limited) in the City and West End of London since 1872, and by MacMahon's Telegraphic News Company (Limited), for the delivery of Parliamentary, Sporting, and General Intelligence, since 1879.

The Company will supply householders and others with its

DISTRICT CALL SYSTEM.

By the aid of a small automatic telegraph instrument a Subscriber can at any hour, day or night, call a messenger, cab, or policeman, or give the alarm of fire, and will obtain the required assistance within three minutes of making the signal. Subscribers, when absent from their homes for a season, can leave their houses closed, and have them taken charge of by the Company, and rendered perfectly secure against burglars by a telegraphic communication with the nearest District Call Station of the Company, where a policeman will always be in readiness day and night to respond to calls.

Provincial combinations to work under the Company's Patents will be treated liberally.

The Company is also prepared to supply Municipalities with its system of

STREET FIRE ALARMS

as recommended by H. M. Postal Telegraph Department to the Metropolitan Board of Works for the Metropolitan Fire Brigade, and which has received favourable mention by Captain Shaw in his last annual report.

These Alarms have recently been considerably improved by the Company, and are acknowledged to be the simplest yet constructed.

All communications to be addressed to the Secretary as above.

MARSHALL, SONS, & CO., LIMITED,

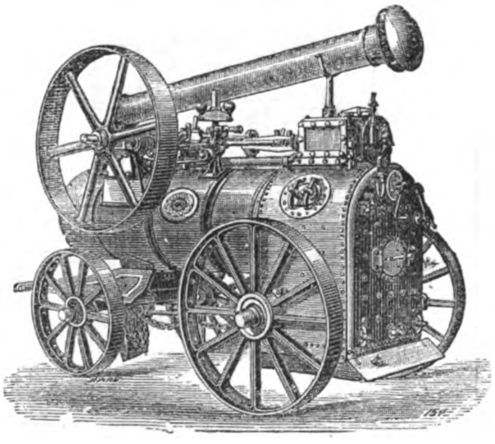
Britannia Iron Works, GAINSBOROUGH, & 3, King Street, Cheapside, LONDON, E.C.

MANUFACTURERS OF

STEAM ENGINES,

Fitted with Patent Automatic Expansion Valve Gear, and

SPECIALLY DESIGNED FOR DRIVING ELECTRIC LIGHT MACHINERY.



OF THE FOLLOWING TYPES:—

HORIZONTAL FIXED ENGINES, with separate Boilers,

HIGH PRESSURE PORTABLE & SEMI-PORTABLE ENGINES,

COMPOUND HIGH & LOW PRESSURE PORTABLE & STATIONARY ENGINES,

As used for driving a large number of the most important Installations in London and the Provinces.

MELBOURNE EXHIBITION, 1881.—Highest Award for all Exhibits. FIVE GOLD MEDALS.

SYDNEY EXHIBITION, 1880.—Two Special First and Four First Prizes.

PARIS EXHIBITION, 1878.—TWO GOLD MEDALS, and other Prizes.

Catalogues in English, French, German, Spanish, or Russian, free on application.

SLIP

BARBADOES.—The sittings of the Telegraph Conference at Barbadoes have closed.

THE CHANNEL TUNNEL.—The electric lights are again in use in the Channel Tunnel Works.

THE CROOKES LAMP.—The Gülcher Electric Light and Power Company have acquired the incandescent lamp of Mr. William Crookes, F.R.S.

WORKING ON THE ATLANTIC CABLE.—The *Operator* states that the first Gould cable, laid in 1881 by Messrs. Siemens Brothers, has attained a working capacity of about seventeen and a half words per minute.

ELECTRIC LIGHT IN SYDNEY.—Recent news from New South Wales states that the South Australian Electric Company had imported the necessary machinery for five electric lights, and would shortly have them in operation in the city.

ANOTHER VOLTA PRIZE.—A fresh Volta prize of 50,000fr. has been created by the French Academy of Sciences for the most remarkable discovery in electricity during the next five years. The competition will close on the 31st of July, 1887.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons due June 30 on the debentures of this company will be paid at the offices, 98, Cannon-street, London. They must be presented for examination three days before payment.

BRUSH MIDLAND ELECTRIC LIGHT AND POWER COMPANY.—We are requested to state that the directors of this company have decided not to make the call of £1 per share fixed for the 1st July, as sufficient capital is in hand for present requirements.

LONDON PLATINO BRAZILIAN TELEGRAPH COMPANY.—The revenue of this company for the month of March, 1882, is estimated at £2,559 (Western Brazilian portion £1,740, land lines £819), as against £2,514 for the corresponding period of 1881.

UNDERGROUND ELECTRIC LIGHT WIRES.—Professor E. J. Houston, of Philadelphia, has investigated the subject of underground wires for electric lighting, and has given his opinion that such a system is perfectly feasible, and certainly safer than overhead wires.

WESTERN BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended the 16th ult. amounted to £1,816, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited).

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half-month ended June 15 are £2,484, as compared with £2,713 in the corresponding period of 1881. The February receipts, estimated at £5,459, realised £5,632.

ELECTRIC LIGHT FOR HELL GATE.—We stated some time since that this dangerous entrance to New York Harbour was to be lighted by the electric light. It has been determined to have two groups of ten arc lamps of 2,000 candle-power each at either end of the passage.

TORNADO IN AMERICA.—A severe tornado passed through Missouri, Illinois, Kansas, and Iowa States recently, doing a great amount of damage, and, amongst other things, wrecking the telegraph lines and entirely interrupting communication in the district through which it passed.

COUPONS.—The Eastern and South African Telegraph Company state that the coupons due this day (July 1) on their Five per Cent. Mortgage Debentures will be paid on presentation by Messrs. Barclay, Bevan, and Co. Coupons must be left three clear days for examination.

THE TELEPHONE IN MINES.—An American contemporary says that the telephone refuses to work in the deep mines on the Comstock, Nevada. The magnets rust in a few hours, so nothing goes through. Some were tried in the Sutro Tunnel, inclosed in air-tight boxes, but they failed to operate.

THE EDISON LIGHT IN CAPE TOWN.—The *Cape Times* of May 13 says:—"The House of Assembly continues to be lighted by the electric light, and the result has so far been highly satisfactory. The light is full, clear, pervasive, and steady, and greatly improves the appearance of the Chamber."

ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS.—The annual meeting of this association was held from Thursday to to-day (Saturday), and took place at the Institution of Civil Engineers. Amongst other papers, Mr. W. Sugg read one on "Gas as An Illuminating Agent Compared with Electricity."

THE COST OF ELECTRICITY.—The cost of supplying electricity for lighting and other purposes to one square mile has been recently stated to be about as follows by the undermentioned authorities on the subject, viz.:—By Dr. Siemens, £400,000; by Dr. John Hopkinson, £200,000; and by Mr. Spottiswoode, £100,000.

PROPOSED ALTERATION OF THE MORSE ALPHABET.—It has been proposed by Mr. W. G. Stevens, in the New York, Pennsylvania, and Ohio Railway Company's telegraph service, to alter the present Morse signal for O or cipher to two dots and two dashes. It is stated that this alteration is likely to be adopted before long in America.

UNDERGROUND TELEGRAPHS IN FRANCE.—In the report of the Budget Committee on the French Posts and Telegraph Estimates for next year it is stated that the network of underground telegraph wires now being laid will cost when finished £2,120,000, of which more than half has already been spent. The system will be about 1,400 miles long.

TELEPHONIC CONCERTS.—Messrs. Tasker, Sons, and Co. gave a series of very successful telephonic concerts in Sheffield last week. The music of a military band was conveyed some miles by wire to large audiences in the Cutler's Hall. More than 200 telephones were brought into use, and the arrangements for the visitors were of the most complete description.

ELECTRICAL RAILWAYS.—A lecture on this subject was given in Trinity College, Dublin, on Monday last, by Dr. A. Traill, and not Dr. Siemens, as we stated in our last issue. The lecturer referred particularly to the electrical tramway now being constructed at Portrush, in the County of Antrim, and exhibited a model car, which was made to work in the lecture room.

BOILING WATER BY ELECTRICITY.—When giving evidence before the Select Committee on the Electric Lighting Bill, Dr. John Hopkinson stated his belief that the whole of the electricity generated by one horse-power would not do more than boil one and a half gallon of water an hour. This was to show that electricity is not likely to be used in the future for heating purposes.

ELECTRIC LIGHT IN BALTIMORE.—The Brush Company have at work ninety-six out of the two hundred and twenty-five electric lamps which they are to supply to the city of Baltimore. The lamps are fixed on poles, eighteen feet high,

Digitized by Google

with swinging globes, the poles being placed from three to six hundred feet apart. We believe that the lights have given great satisfaction.

Telegraphic Delay.—Our contemporary the *Globe* remarks in its issue for the 24th June :—"Two hours and twenty-two minutes is rather a long time, considering the modern facilities, for a message to get from Westminster to the Strand. Yet this is the time a telegraphic message takes —at all events, took yesterday," and adds sarcastically, "one could almost walk the distance in the time."

Markland Electric Light Company.—This company announce that the shares offered to the public not having been fully subscribed the deposits paid on application will be returned at once without deduction. The company also announce that on the arrival of a large consignment of their lamps, which they have ordered from New York, a full installation of their system will be publicly made.

Central and South American Cable.—The India Rubber, Gutta Percha, and Telegraph Works Company have received a telegram from their engineer, Mr. Robert Kaye Gray, on board the steamship "Silvertown," announcing the laying, on the 21st inst., of the Buenaventura-Panama section of the Central and South American Telegraph Company's cable, by which that company's system is completed from Lima to Panama.

New Atlantic Cable Company.—An American contemporary says the American Atlantic Cable Company of New York has filed amended articles of incorporation. The general route of the line of telegraph is from New York City to a point convenient upon the coast of the United States, and thence to the coast of Portugal, Spain, or France in Europe. The capital is 10,000,000 dollars, which can be increased at the discretion of the stockholders.

Alexandria.—The *Standard* correspondent at Alexandria says:—To-day (Sunday, 25th June) I inspected the Eastern Telegraph Cable Company's organisation. It is admirable. They are prepared at a moment's notice to transfer their staff and instruments outside the harbour. Communication will not be interrupted for half an hour." It is stated that in case of emergency this company's offices will form the rendezvous for all the Europeans in the city.

New American Telegraph Company.—The Northern Mutual Telegraph and Telephone Company has been formed. The general route of the line is through the State of New York from east to west and from the city of Oswego eastward and westward. The points to be connected are the city of New York, and cities of Syracuse, Oswego, Ogdensburg, Buffalo, Elmira, Binghamton and Albany. The capital is 250,000 dollars, with the provision that it may be increased to 1,000,000 dollars.

Electric Light Wires and Chicago Firemen.—The decision of the mayor and chief magistrates of Chicago that electric light wires must be placed underground is said to have been greatly influenced by the representations of the firemen of that city. The men stated that their lives were placed in danger when the wires were run overhead, asserting that if a fire took place near the wires the insulation would be melted off and the wires thus rendered dangerous to any person coming in contact with them.

Electric Railway in Holland.—The first electric railway constructed in Holland was opened a few days since. It runs from the Bath at Zandvoort, near Amsterdam, to Kostuerloren, a small park in the neighbourhood. It is one kilometre and a half long. The line has been constructed on the system of Messrs. Siemens and Halske, of Berlin, the steam engine used being of 15 horse-power. The current is conducted along the rails and through the wheels to a dynamo under the car. The gauge of the railway is one metre.

Crystal Palace.—It is proposed by the Crystal Palace authorities to organise an exhibition in the coming autumn and winter, which shall include both gas and electric lighting. The exhibition is to be of an international character, and it is hoped that the latest improvements in both cases will be well represented. This is an excellent move and one in the right direction. We have no doubt that electric light engineers will enter heartily into the project, and do their best to show what their light can do in direct competition with gas.

The Sun Lamp.—This lamp, better known on the Continent as the Lampe-Soleil, was exhibited on Saturday last in the vaults of the Royal Exchange. Our readers will remember that we illustrated this lamp as in use at the Paris Opera House in a recent number. It is the invention of M. Clerc and M. Bureau, of Brussels. In this lamp two carbons impinge upon a block of marble, which latter becomes incandescent when the arc has been established, and gives the pleasant mellow light which has led to its being named the Sun lamp.

Electric Light at King's Lynn (Norfolk).—An introduction of the electric light has just been made into King's Lynn at Messrs. Walker's mill. This contract has been carried out most successfully by the British Electric Light Company (Limited) with the Gramme machine and sixty-two British incandescent lamps. Messrs. Walker believe that the lighting will cost much less than they have hitherto paid for gas. A Brockie arc lamp of 6,000 candle-power has also been suspended in the market place from a davit 47ft. above the street level, and throws a flood of brilliant light over the whole of the market place and the adjoining thoroughfare.

The Jablochkoff Light.—According to figures which have been afforded by Messrs. Samuel Brothers, of Ludgate Hill, the cost of the Jablochkoff lights there is only £150 per annum, the premises being lighted on an average three hours each night. There are 20 lights altogether, each giving 378 candle-power, equal to about 35 ordinary gas burners. These are driven by a 12 h-p. Otto gas engine. The cost is estimated as follows:—Jablochkoff candles, 1d. per hour for each lamp; gas consumed in Otto engine also 1d. per hour for each lamp—total 2d. Five of the above lights are employed outside the premises, the remainder light up a space of 4,000 square feet.

Underground Telegraph Wires at Pittsburgh.—A company formed to work a patent taken out by Mr. Worrell, a brass founder of Pittsburgh, U.S.A., for a new system of underground cables, have obtained leave from the Town Council to lay an experimental cable for testing purposes. The cable will be laid from Negley's Run to the centre of the city, a distance of seven miles. It is stated that the inventor constructs his cable of corrugated lead, one inch in diameter, perforated with five small holes, through which the wire is drawn. The composition of the insulating material is not known. According to the latest account, the laying of the cable had been begun.

Electric Lighting in Italy.—Sixty Edison incandescent lamps, A size, have been fitted up in the cotton mill of Signor Benigno Crespi, of Vaprio, and have worked satisfactorily for some time past. Messrs. Cavaliere and Franco, of Bologna, have also adopted these lamps in their flour mill, and are said to be very satisfied with them. Sixty A lamps

Digitized by Google

are used in this case also. Arrangements are nearly completed for fixing 120 B lamps in the cotton mill of Cavaliere Andrea Ponti, of Solbiate Vlona, near Bristo. The whole of these installations have been carried out under the superintendence of Mr. James Shepherd, the very able and energetic representative of the Edison Company in Milan.

Electric Lighting in the City.—According to an abstract of the tenders recently sent in to the Commissioners of Sewers for lighting three new districts, and the district lately lighted by Messrs. Siemens Bros. in the city, the prices were very variable. The figures are for twelve months' supply of light, including fixing machinery, &c. The prices vary for district No. 1 from £2,190 to £5,750, the present cost of gas being £551; for district No. 2 the figures fluctuate between £2,350 and £4,270, the cost of gas being £363; for district No. 3 the prices vary from £2,470 to £3,800, cost of gas, £341; and in district No. 4 they go from £2,920 to £4,350, against £612 for gas.

Telephonic Sounds.—The *Operator* says: "Mr. Nat. G. Warth, manager of the Midland Telephone Company, at Gallipolis, O., writes: 'Please give some one the chance of explaining this phenomenon. This morning early, while in temporary communication over a Western Union wire with Major R. B. Hoover, at Pomeroy, Ohio, twenty miles away I could distinctly hear the croaking of frogs and the singing of birds. The wire passes through dense woods, and along large streams between the two points. There were only the two sets of instruments in circuit. The sounds certainly were taken up and transmitted from some point between us. Now, by what law could this occur? Could the sound have been induced by a damp atmosphere?'"

Post Office Telegraphs.—In the House of Commons on Thursday week Mr. A. Morley asked the Postmaster-General if it was proposed to apply to the Engineers' Department of the Post Office a scheme similar to that which was applied last year to the Commercial Department; and, in the event of its being so proposed, if he could state whether the scheme had yet been approved; how soon it was expected that it would be published; and whether it would date back to April in last year, as was the case with the scheme applied to the Commercial Department. Mr. Fawcett replied that the scheme was settled, and that instructions had already been given for putting it in force from the 1st of April, 1881. Mr. Stewart Macliver, M.P., has also received a letter from the Postmaster-General confirming this.

Electric Lighting Bill.—Mr. Barran has given notice that on the House going into committee on the Electric Lighting Bill he will move the insertion of the following clause in the Bill:—"Notice of application for Provisional Order.—No application for a Provisional Order on the part of any company or person shall be made in respect of all or any part of the district of a municipal or other local authority without nine months' notice in writing (which shall define the area intended to be comprised therein) to such authority, who shall within that period, but subject to the last-mentioned provision (Clause A), be entitled to make application for a Provisional Order in respect of all or any part (including the area defined in such notice) of such district; and, until such application has been disposed of, no other application shall be entertained."

Secondary Batteries.—Patents were taken out in America on the 14th and 28th October, 1879, by Professors Thompson and Houston for a storage battery. It is stated that the Brush Company and the American Company of New Britain are disposed to contest the Faure patent on the ground that it was anticipated by the above-mentioned patents. The first claim of the patent, dated October 14, is as follows:—"The combination in a cell for voltaic batteries of an enclosing vessel, two conducting plates (neither of which is electro-positive), one serving as a receiver for electro-positive metal and the other as a source of supply for the formation of an electro-negative resultant, and a solution in which said plates are immersed, said solution being incapable of generating electrical action until the passage through it of an electrical current," &c.

Precautions Against Fire.—The Anglo-American Brush Electric Light Corporation have decided that their premises in Mansfield-street, Borough, shall be provided with such means as will enable their *employés* to cope with any outbreak of fire which might occur, independently of outside assistance, and during the period which must necessarily elapse between the discovery of flames and the arrival of a fire engine. Messrs. Merryweather and Sons, of Long-acre and Greenwich, have been instructed to fix eight of their improved high pressure fire hydrants upon the premises, which will be constantly charged from two points of the water company's main, and each hydrant supplied with a full complement of leather fire hose and nozzles. The arrangement has been devised by Mr. J. H. Heathman, the author of "On the Preservation of Life and Property from Fire," under whose supervision the work will be carried out.

The Anglo-American v. Scotch Brush Company.—The petition of the Anglo-American Brush Electric Light Company praying that the affairs of the Scottish Brush Electric Light Company might be wound up was heard in the Court of Session, at Edinburgh, on the 22nd June. The Court decided that the petition was premature, and dimissed the case with costs against the petitioners. The question in dispute was whether an undue proportion of the shares in a new company, to be called the Brush Company of Scotland, floated by the Scottish company, had been illegally allotted to shareholders in the Scottish company, thereby depriving the Anglo Company of shares which should have come to them. The answer made by the Scottish company was that the time for issuing the remaining shares of their company was extended for six months from 31st December last, and that therefore the present petition was premature. Judgment was given as above mentioned.

Overtime in the Post Office.—In reply to a question asked by Mr. Stuart Wortley in the House of Commons on Monday last as to whether under Sec. 7 of the new scheme "it was intended that overtime work on Sundays should be in all cases separately accounted and paid for, and whether he approved of such a construction of that section as reckoned Sunday overtime work in substitution of time not worked out on any of the other six days of the week," Mr. Fawcett replied that a sorting clerk and telegraphist is liable for the performance of an average of two hours' duty on each Sunday, so that the attendance does not exceed eight hours in four consecutive Sundays, and a separate record is kept of this attendance. Including the two hours on Sunday he must perform fifty hours' work a week. He was not aware that this rule had been departed from in the manner implied by the hon. member, but on receipt of specific information about any individual case he would be glad to inquire into it.

Electric Light in Manchester.—The Royal Exchange, Manchester, is being lighted by the British Electric Light Company, the work being carried out under the superintendence of Mr. J. M. Emmerson, of Stockport. The large central hall is to be lighted by nine arc lights, of 6,000

Digitized by Google

candle-power, and the side corridors and offices by 210 incandescent lamps. The main entrance is also lighted by three arc lights. A Gramme machine, driven by a 25 horse-power engine, is used. The dining rooms and restaurants have been lighted with Swan incandescent lamps, by Messrs. Gooch and Hüne, of London and Manchester, Siemens alternate current machines being used, together with a Crossley 12 horse-power gas engine. At present there are 154 lamps in operation, but in the winter months this number will be increased to 210. The 154 lamps are at present on one circuit; but when the larger number are employed it is intended, we believe, to introduce Faure accumulators to supply the other lamps.

LEGAL.—SEAVER V PHILIPPART.—This was an action brought by Mr. F. I. Ricarde-Seaver, against M. Philippart as President of the Société la Force et la Lumière, a Belgian company, to restrain the issue of any shares in the Faure Electric Accumulator Company of London to the above-mentioned Belgian company until 5 per cent. commission on such shares had been paid to Mr. Ricarde-Seaver, on account of certain services rendered by him to M. Philippart. We referred to this case in a note in our issue of June 3, when an interim injunction was granted by Vice-Chancellor Hall. The case came before Mr. Justice Kay, sitting for Vice-Chancellor Hall, on the 15th instant. The evidence relied upon by the plaintiff was a letter, dated 6th April, 1882, in which M. Philippart had agreed to give Mr. Seaver a commission of "an amount equal to 5 per cent. of the net profits either in money or shares," which might be realised by the Belgian company. Mr. Justice Kay held that the terms of the letter did not entitle the plaintiff to any specific portion of or charge upon the shares in question, and he accordingly refused the application.

NEW FORM OF ELECTRIC LIGHTING MAINS.—A new form of underground main for conducting powerful currents, such as are used for electric lighting or for manufacturing and motive purposes, has recently been invented by a Detroit man. The main consists of a No. 6 copper wire, which is placed exactly in the centre of a copper or brass tube about $\frac{7}{8}$ inch in diameter and 1-16 inch in thickness. The wire is insulated from the tube by means of an insulation consisting of a mortar or putty made in the most refractory sulphate of lime mixed with a heavy oil, and injected by means of heat into the tube. The copper tube is wound with kerite tape, and, being surrounded by a layer of the insulating material, is encased in a protecting pipe of iron—a common $1\frac{1}{2}$ inch gas-pipe. The main is intended to be made in sections of 12 to 15 feet, which connect with one another by means of screw-joints. When the end of the line is arrived at, a metal cap, insulated from the gronnd, is screwed on, thus closing the circuit. The main has at certain fixed points—for instance, every 1,000 feet—a box at which the circuit may be "short-circuited," in order to facilitate any repairs which in the course of human events may become necessary.—*Operator*.

ELECTRIC LIGHT WIRES AND FIRES.—Mr. Drummond, British Secretary of Legation at Washington, makes some remarks on fires caused by electric lights in a recent report. He calls attention to a report by Inspector McDevitt, of Philadelphia, on a fire which took place at Randolph Mill, and which was attributed to the circumstance that wires were fastened to the ceilings and walls, without insulation, by bare iron staples. According to another authority fires originated in one of the largest manufacturing houses in that city on more than one occasion, though in these cases the wires were insulated. One of the staples, however, had worn through the covering until the two metal surfaces touched. It then only required moisture in the wood of the rafter to draw the sparks into the dry wood beyond. On the first occasion water was dashed on the place, but it was found that it only increased the flames, and the fire could only be extinguished by tearing the wires down bodily. Unaccountable fires are said to have originated under the cornices of houses in New York, which it is reported can only be explained on the supposition that an electric wire passing over the roof had been carelessly allowed to rest upon the tin or galvanised iron surface, which was in contact with wood underneath.

WEATHER FORECASTS.—In the House of Commons, on Friday (23rd June), Mr. Birkbeck asked the Postmaster-General whether he would allow the daily weather forecasts issued by the Meteorological Office to be sent to, and exhibited at, every postal telegraph office throughout the agricultural districts for the benefit of farmers during the hay season and harvest. Mr. Fawcett said:—"This subject has already been brought under my notice by my hon. friend the member for Newark (Mr. Earp), and, according to a promise I gave at the end of last Session, I have very carefully looked into the matter to which the question of the hon. member refers. I regret that I do not see my way to accede to his request, because it appears that if the Government supplied telegrams gratuitously to those interested in agriculture it would be impossible to refuse similar applications from those engaged in other trades. I believe that there would be little difficulty in securing the object desired. I understand that the Meteorological Office supplies the weather forecasts gratuitously to anyone who is willing to pay the expenses of telegraphing them, which is very rarely more than one shilling. If, therefore, the farmers in any district jointly subscribe, the expense to each would be very inconsiderable. The forecast might be exhibited at the post-office, and in the case of those farmers who resided within the area of free delivery the messages could be delivered at the small extra cost of 3d. for each additional copy."

SIXPENNY TELEGRAMS.—A letter appeared in *The Times* of Thursday over the signature "Telegram," in which the writer alludes to the statement made by Mr. Fawcett in the House of Commons, given in full in another column, and criticises the refusal of the Government to allow the experiment of sending sixpenny telegrams for a certain period to be made. The writer says:—"Why the Government should have declined to make such an experiment when no loss could possibly accrue to the revenue is one of those matters which can only be understood by a permanent official. The refusal to test an experiment which could be conducted without cost seems to the ordinary mind to be the grandest proof of the bureaucratic obstruction to all improvement which is believed to prevail to a large extent in the Government offices. The question raised, however, by Mr. Stanhope leads to broader considerations than a mere experiment in telegraphic facilities. It can hardly be doubted but that if the telegraphic wires of the country were in the hands of private companies and were administered by private enterprise, instead of being a Government monopoly, the public would gain largely in rapidity, cheapness, and extension of telegraphic communication. It appears more than doubtful whether the monopoly given by Parliament and the purchase by the Government of the telegraph lines in the United Kingdom have not proved to be errors, and whether the time will not shortly arrive when the administration of telegraphy should be taken out of the hands of the Government and again intrusted to private enterprise." Our opinion on this matter will be found in our leading article.

ON THE SEVERAL SYSTEMS OF UNITS FOR ELECTRIC AND MAGNETIC MEASUREMENTS.*

BY R. CLAUSIUS, HON. M. INST. C.E.

There are two systems of units for electrical measurements —the electrostatic and the electro-dynamic. In describing the derivation of these systems from the fundamental units of mass, length, and time, the author in general follows Maxwell's treatise ("Electricity and Magnetism"); but points out an error in the dimensions of the electrostatic unit of magnetic quantity. This is deduced from the electrostatic unit of electricity by means of Ampère's theory. Consider two equal plane figures of unit area bounded by closed curves, in parallel planes, indefinitely near each other. Let currents of unit strength flow in opposite directions round these curves, and denote the perpendicular distance between the planes by $\epsilon\,\pi$, where π is the unit of length, and ϵ a numerical quantity. Then by Ampère's proposition such a system produces the same effects as if the figures had been uniformly coated with an amount $\frac{m}{e}$ of magnetic matter of opposite signs, m being the unit of magnetic quantity; and the magnetic moment is equal to the product of the current intensity and the area. Hence—

$$\frac{m}{\epsilon}\,\epsilon\,\pi = e\,\pi^2\,\tau^{-1},$$

or

$$\frac{m}{e} = \pi\,\tau^{-1}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Now the dimensions of e_s, the electrostatic unit of electricity, are $\mu^{\frac{1}{2}}\,\pi^{\frac{3}{2}}\,\tau^{-1}$, and of m_d, the electro-dynamic unit of magnetic quantity $\mu^{\frac{1}{2}}\,\pi^{\frac{3}{2}}\,\tau^{-1}$, μ denoting the unit of mass, and τ the unit of time.

Hence

$$m_s = \mu^{\frac{1}{2}}\,\mu^{\frac{5}{2}}\,\tau^{-2}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

and

$$e_d = \mu^{\frac{1}{2}}\,\pi^{\frac{1}{2}}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Maxwell derives his units from the equations

$$m\,c = \frac{\pi^2\,\mu}{\tau^2} \quad \text{and} \quad \frac{e}{c} = \tau,$$

where c is the unit of current.

Hence

$$e\,m = \mu\,\pi^2\,\tau^{-1};$$

therefore

$$e_d = \mu^{\frac{1}{2}}\,\pi^{\frac{1}{2}}.$$

But the equation is only applicable to the electro-dynamic system, and when applied to the electrostatic system gives the wrong result,

$$e_s\,m_s = \mu\,\pi^2\,\tau^{-1},$$

and therefore

$$m_s = \mu^{\frac{1}{2}}\,\pi^{\frac{1}{2}}.$$

After defining the other electrical units, the author compares the two systems. The force between two electrostatic units of electricity at unit distance is the unit of force, and is therefore equal to $[e_s^2\,\pi^{-2}]$. Let $k\,[m_s^2\,\pi^{-2}]$ represent the force between two electrostatic units of magnetic quantity at unit distance. This can be written $k\,[\pi^2\,\tau^{-2}]\,[e_s^2\,\pi^{-2}]$. But the last factor is the unit of force, and the whole expression is a force; hence k is the reciprocal of the square of a velocity, called by the author the critical velocity, and denoted by K. The force between two electrostatic units of magnetic quantity at unit distance is, therefore, $[\pi^2\,\tau^{-2}]\,[\mathrm{K}^{-2}]$ of a unit of force, but the force between two electro-dynamic units of magnetic quantity at unit distance is the unit of force; hence, since the forces vary as the squares of the quantities, the ratio between the magnetic units is as K to $[\pi\,\tau^{-1}]$. This can be expressed by the equation

$$\frac{v.\,s.\,[m_d]}{[m_s]} = \frac{[m_d]}{v.\,d.\,[m_s]} = \frac{\mathrm{K}}{\pi\,\tau^{-1}},$$

where the prefix $v.\,s.$ denotes that the electro-dynamical unit is expressed in electrostatic measure, and $v.\,d.$ that the electrostatical unit is expressed in electro-dynamic measure. By means of the former equations this equation gives

$$m_s = \mu^{\frac{1}{2}}\,\pi^{\frac{5}{2}}\,\tau^{-2}; \quad m_d = \mu^{\frac{1}{2}}\,\pi^{\frac{3}{2}}\,\tau^{-1}.$$

From equation (1)

$$[e_s] = [m_s]\,[\pi^{-1}\,\tau]; \quad [e_d] = [m_d]\,[\pi^{-1}\,\tau].$$

Hence

$$v.\,d.\,[e_s] = v.\,d.\,[m_s]\,[\pi^{-1}\,\tau]; \quad v.\,s.\,[e_d] = v.\,s.\,[m_d]\,[\pi^{-1}\,\tau],$$

and

$$\frac{v.\,s.\,[e_d]}{[e_s]} = \frac{[e_d]}{v.\,d.\,[e_s]} = \frac{\mathrm{K}}{[\pi\,\tau^{-1}]},$$

and

$$e_s = [\mu^{\frac{1}{2}}\,\pi^{\frac{3}{2}}\,\tau^{-1}]; \quad [e_d] = [\mu^{\frac{1}{2}}\,\pi^{\frac{1}{2}}].$$

The units of resistance, current, capacity, and electromotive force are similarly deduced.

As the Paris Electrical Congress has decided to give the name of Ampère to the practical unit of current, the author proposes to reserve the name Weber for the electro-dynamical unit of magnetic quantity. The system of units in practical use is then

$$\text{Weber} \ldots\ldots\ldots \quad [m_d] = g\,r^{\frac{1}{2}}\,c\,m^{\frac{3}{2}}\,s^{-1}\,10^8 = p^{\frac{1}{2}}\,q^{\frac{3}{2}}\,s^{-1}.$$

$$\text{Coulomb} \ldots\ldots \quad [e_d] = g\,r^{\frac{1}{2}}\,c\,m^{\frac{1}{2}}\,10^{-1} = p^{\frac{1}{2}}\,q^{\frac{1}{2}}.$$

$$\text{Ampère} \ldots\ldots \quad [i_d] = g\,r^{\frac{1}{2}}\,c\,m^{\frac{1}{2}}\,s^{-1}\,10^{-1} = p^{\frac{1}{2}}\,q^{\frac{1}{2}}\,s^{-1}.$$

$$\text{Volt} \ldots\ldots\ldots\ldots \quad [\mathrm{E}_d] = g\,r^{\frac{1}{2}}\,c\,m^{\frac{3}{2}}\,s^{-2}\,10^8 = p^{\frac{1}{2}}\,q^{\frac{3}{2}}\,s^{-2}.$$

$$\text{Ohm} \ldots\ldots\ldots \quad [\mathrm{R}_d] = c\,m\,s^{-1}\,10^9 = q\,s^{-1}.$$

$$\text{Farad} \ldots\ldots\ldots \quad [\mathrm{C}_d] = c\,m^{-1}\,s^2\,10^{-9} = q^{-1}\,s^2.$$

In the second column the unit of mass p being taken as $1^{gr}\,10^{-11}$, the unit of length q as $1^{cm}\,10^9$, and the unit of time remaining the second.

The author concludes by describing a new system, which he calls the critical system. The ratio of each unit in the dynamical system to the corresponding unit of the statical system is equal to the ratio, or a power of the ratio of the critical velocity to the unit of velocity; hence, if the unit of velocity be chosen equal to the critical velocity, this ratio will in each case be unity. It is convenient to keep the second as the unit of time. The unit of length (λ) is therefore the space passed over in a second by a point moving with the critical velocity; and is equal approximately to 30 quadrants of the meridian. The unit of mass (μ) is chosen, so that the units of currents and quantity retain the same value in the new system as in the practical system. Since

$$[e_d] = p^{\frac{1}{2}}\,q^{\frac{1}{2}} \text{ and } [i_d] = p^{\frac{1}{2}}\,q^{\frac{1}{2}}\,s^{-1},$$

and

$$[e_d] = \lambda^{\frac{1}{2}}\,\mu^{\frac{1}{2}} \text{ and } [i_d] = \mu^{\frac{1}{2}}\,\lambda^{\frac{1}{2}}\,s^{-1},$$

if the values of the units remain the same

$$\mu = p\,\frac{q}{\lambda}.$$

This makes μ approximately equal to $\frac{1}{3}\,10^{-12}\,c\,m$. The critical system is then

$$[m_d] = v.\,d.\,[m_s] = \mu^{\frac{1}{2}}\,\lambda^{\frac{3}{2}}\,s^{-1} = \frac{\lambda}{q} \text{ weber.}$$

$$[e_d] = v.\,d.\,[e_s] = \mu^{\frac{1}{2}}\,\lambda^{\frac{1}{2}} = 1 \text{ coulomb.}$$

$$[i_d] = v.\,d.\,[i_s] = \mu^{\frac{1}{2}}\,\lambda^{\frac{1}{2}}\,s^{-1} = 1 \text{ ampère.}$$

$$[\mathrm{E}_d] = v.\,d.\,[\mathrm{E}_s] = \mu^{\frac{1}{2}}\,\lambda^{\frac{3}{2}}\,s^{-2} = \frac{\lambda}{q} \text{ volt.}$$

$$[\mathrm{R}_d] = v.\,d.\,[\mathrm{R}_s] = \lambda\,s^{-1} = \frac{\lambda}{q} \text{ ohm.}$$

$$[\mathrm{C}_d] = v.\,d.\,[\mathrm{C}_s] = \lambda^{-1}\,s^2 = \frac{q}{\lambda} \text{ farad.}$$

Though this system is of no practical use, since the critical velocity is not sufficiently accurately known, it is of theoretical value from the agreement of the electro-dynamic and electrostatic units.

SAFETY JUNCTIONS AND PLUGS FOR INCANDESCENT LIGHTING.

Messrs. Edmunds and Co., Halifax, Yorkshire, have lately designed and registered a new form of safety plug, to supply a want greatly felt in making installations of electric lighting upon the incandescent principle. Until their introduction, the only safety plug in the market was that devised by Mr. Edison, and not only were they far from perfect either in operation or appearance, but unattainable by those who wished to use any system but the Edison.

Instead of lead wire, which oxidises, and is eaten away by exposure, Messrs. Edmunds and Co. employ tin, lead, or other metal foil, so attached to an insulating substance, that neither

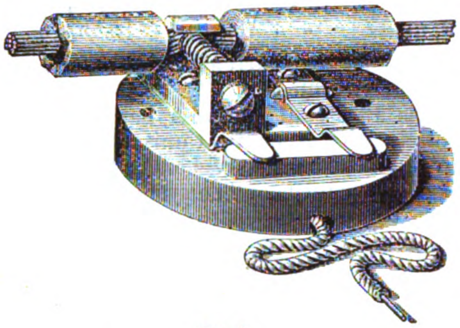

Fig. 1.

heat nor damp will loosen it; and of such bulk that it will carry enough current for one lamp, and but little more. The foil is of such a shape and section as to "go" always in the centre of the plug upon a lamp being short-circuited, thus preserving the contacts bright and clean. These little plugs can be punched out from a sheet of material with great ease, and from their very nature cost but little.

The main lead is attached to the screw junction as shown by baring the wire of its dielectric for about the width of the junction, and placing the bared wire in the junction, and then screwing up tightly. The current passes from the main lead through the junction and spring to the fusible or safety plug, then on to the second spring, and so on by the small wire to the lamp. The whole safety junction is then covered

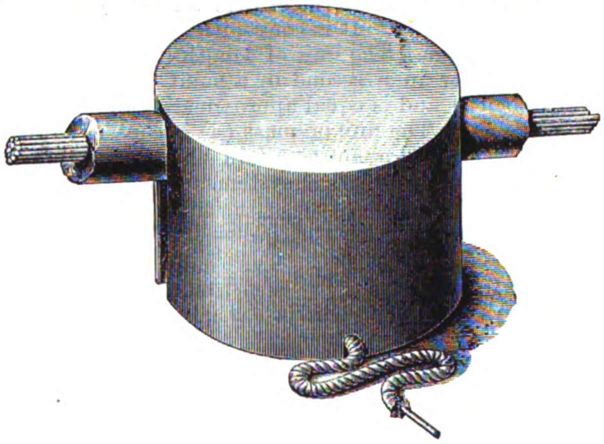

Fig. 2.

over by the cap as shown in the second figure, this being done after the junction has been screwed to the wall by two screws passing through the wooden disc as shown.

When a number of lamps are to be grouped together, as in an electrolier, it is inconvenient to place a number of safety junctions together, and such an arrangement would appear unsightly. The firm before mentioned have, therefore, brought out a registered arrangement, by which a number of plugs can be grouped together under one cover. This is shown in the third figure, which represents an 8 plug box. The main lead is attached to the screw junction, as described before, and each lamp has a wire attached to a little terminal outside the box, as shown. By this means every lamp in the electrolier in question has its fusible safety plug, and the whole number are easily got at to replace one when burnt. The foil has been so proportioned that it "goes" without making the other lamps "jump" in the least. A number of these useful and really necessary little articles are already in use, and so far have answered the purposes for which they are made admirably.

Fig. 3.

In the numerous installations made by Messrs. Edmunds these appliances are extensively employed, and are now coming into general use with those companies who do most of the incandescent electric lighting in this country.

MILNER'S WIRE GAUGES.

We illustrate two forms of wire gauge, recently patented by Mr. Milner, which are a decided improvement on the old

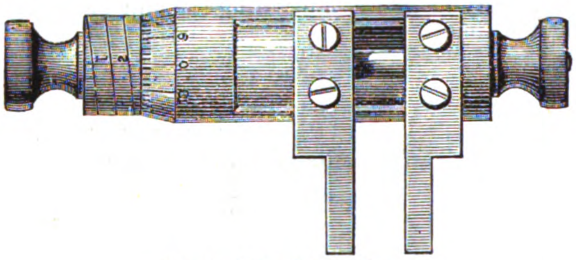

Fig. 1.—Milner's Wire Gauge.

form hitherto in use. The principle of both of them is that of the well-known diagonal scale. In the form represented

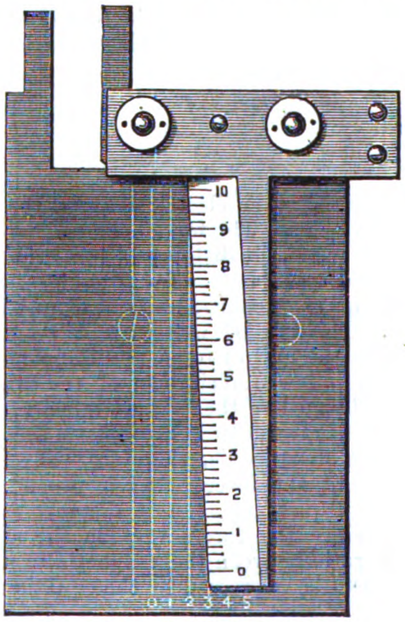

Fig. 2.—Milner's Wire Gauge.

in Figure 1, the scale is described as a spiral line round a cylinder.

In the other form, Fig. 2, the reading is obtained by the

edge of the bar, inclined as shown, which moves over the surface of the flat plate. One of these is marked for measurements up to ·5 inch, whilst the other has ten sets of figures by means of which measurements up to ·001 inch can be made. The bar is compelled to move properly by a simple parallel rule arrangement at the back of the plate.

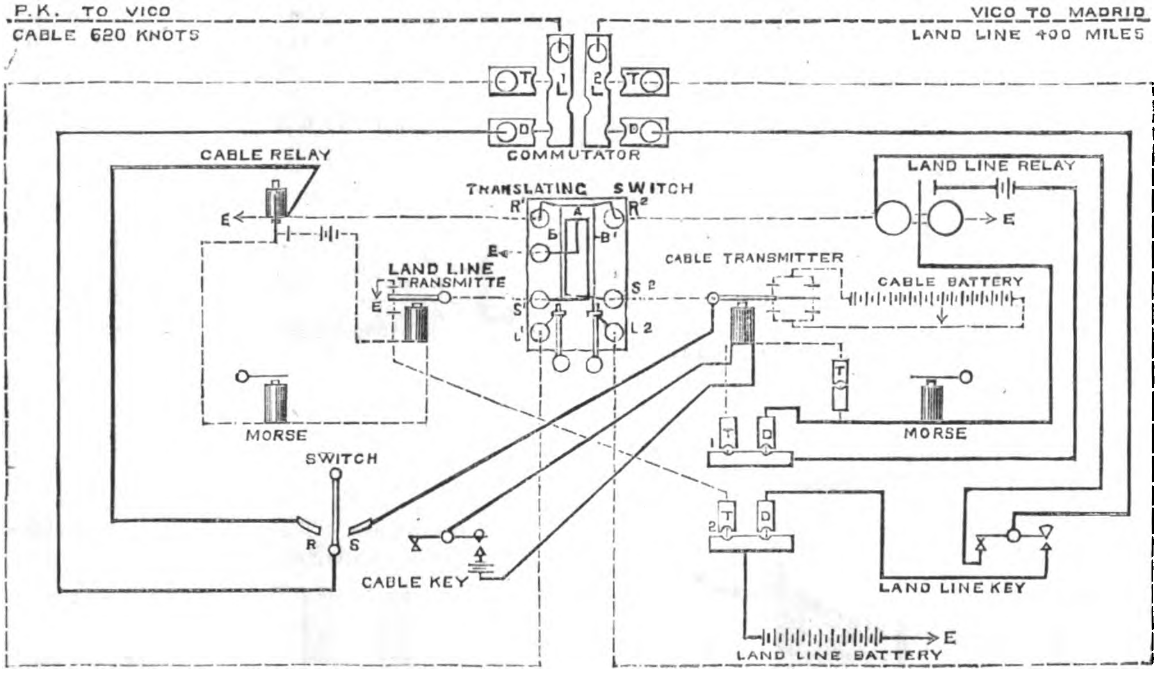
One great merit of these little gauges is that they are far handier than the old form, and can be held in one hand only, leaving the other free to manipulate the wire. Both inside and outside measurements can be obtained with them.

They are manufactured by Messrs. Elliott Brothers, of the Strand, and this is a sufficient guarantee for their accuracy. The instruments we have seen show excellent workmanship. Our illustrations represent the instruments full size.

THE CRYSTAL PALACE EXHIBITION.

Eastern Telegraph Company.

We herewith illustrate Saunder's translating arrangement as used on the lines of the Eastern Telegraph Company, and shown by that company at the Crystal Palace Exhibition.



NOTE
DOTTED LINES = TRANSLATING CIRCUIT. SOLID LINES = DIRECT WORKING

Saunders' Translating Arrangement.

The diagram shows the apparatus and the way in which the various parts are connected; the only parts requiring explanation are the translating switch and the cable transmitter. The translating switch consists of two levers, having a vertical movement, and connected respectively with terminals L^1 and L^2, and a vertical block of vulcanite, A, having three contacts on each side, with which the springs B B^1 of the levers make contact. The contacts on each side at the bottom of the block are connected respectively with terminal R^1 and R^2, the contacts on the top of the block are connected to S^1 and S^2, intermediate contacts between R^1 R^2 and S^1 S^2 are connected to the terminal E.

The levers are so arranged that the springs B B^1 can both be put on to the contact R^1 R^2 of A, but are so connected together that depressing one raises the other and *vice versâ*, so that the levers are alternately in contact with the top and bottom contacts on A, as one or other of the levers is depressed.

The cable transmitter has, in addition to rigid contacts, rubbing spring contacts so as to insure perfect signals on the cable, and this transmitter sends the current through the cable whether working translation when it is actuated by the local battery of the land line relay, or working in sections when it is actuated by the local battery of the cable key.

The action is as follows for working translation from Porthcurnow to Madrid, through Vigo:—The apparatus being connected up as shown by dotted lines in the diagram, plugs being inserted into the commutator and plug switches marked T, both levers raised so that the springs B B^1 rest upon the *lower* contacts on vulcanite block A; then the cable and land-line are connected to their respective relays, so that either station can call up the intermediate or terminal station. Should Porthcurnow call up Madrid, the intermediate station, Vigo, would depress the right-hand lever, and thus place the land-line in connection with the land-line transmitter, putting Porthcurnow in translating circuit with Madrid. Thus the current sent from Porthcurnow would pass through commutator L^1 T to translating switch lever L^1 to lower contact on A through cable relay to earth. The cable relay corresponding to this current would actuate land-line transmitter, which would send corresponding currents on to Madrid through terminal S^1 connected to top right-hand contact on A by right-hand lever connected to terminal L^2 and thence to commutator L^2 T. On Madrid wishing to send to Porthcurnow the clerk at Vigo would depress the left-hand lever, which would reverse all the connections. The land-line relay would now respond and bring into play the cable transmitter, and so on alternately.

The one action of depressing either of the levers raises the other so that the springs B B^1 rest alternatively on the top or bottom contacts of A.

The intermediate contacts (connected to earth) between the top and bottom ones on A discharge the lines as they come in contact with them in passing.

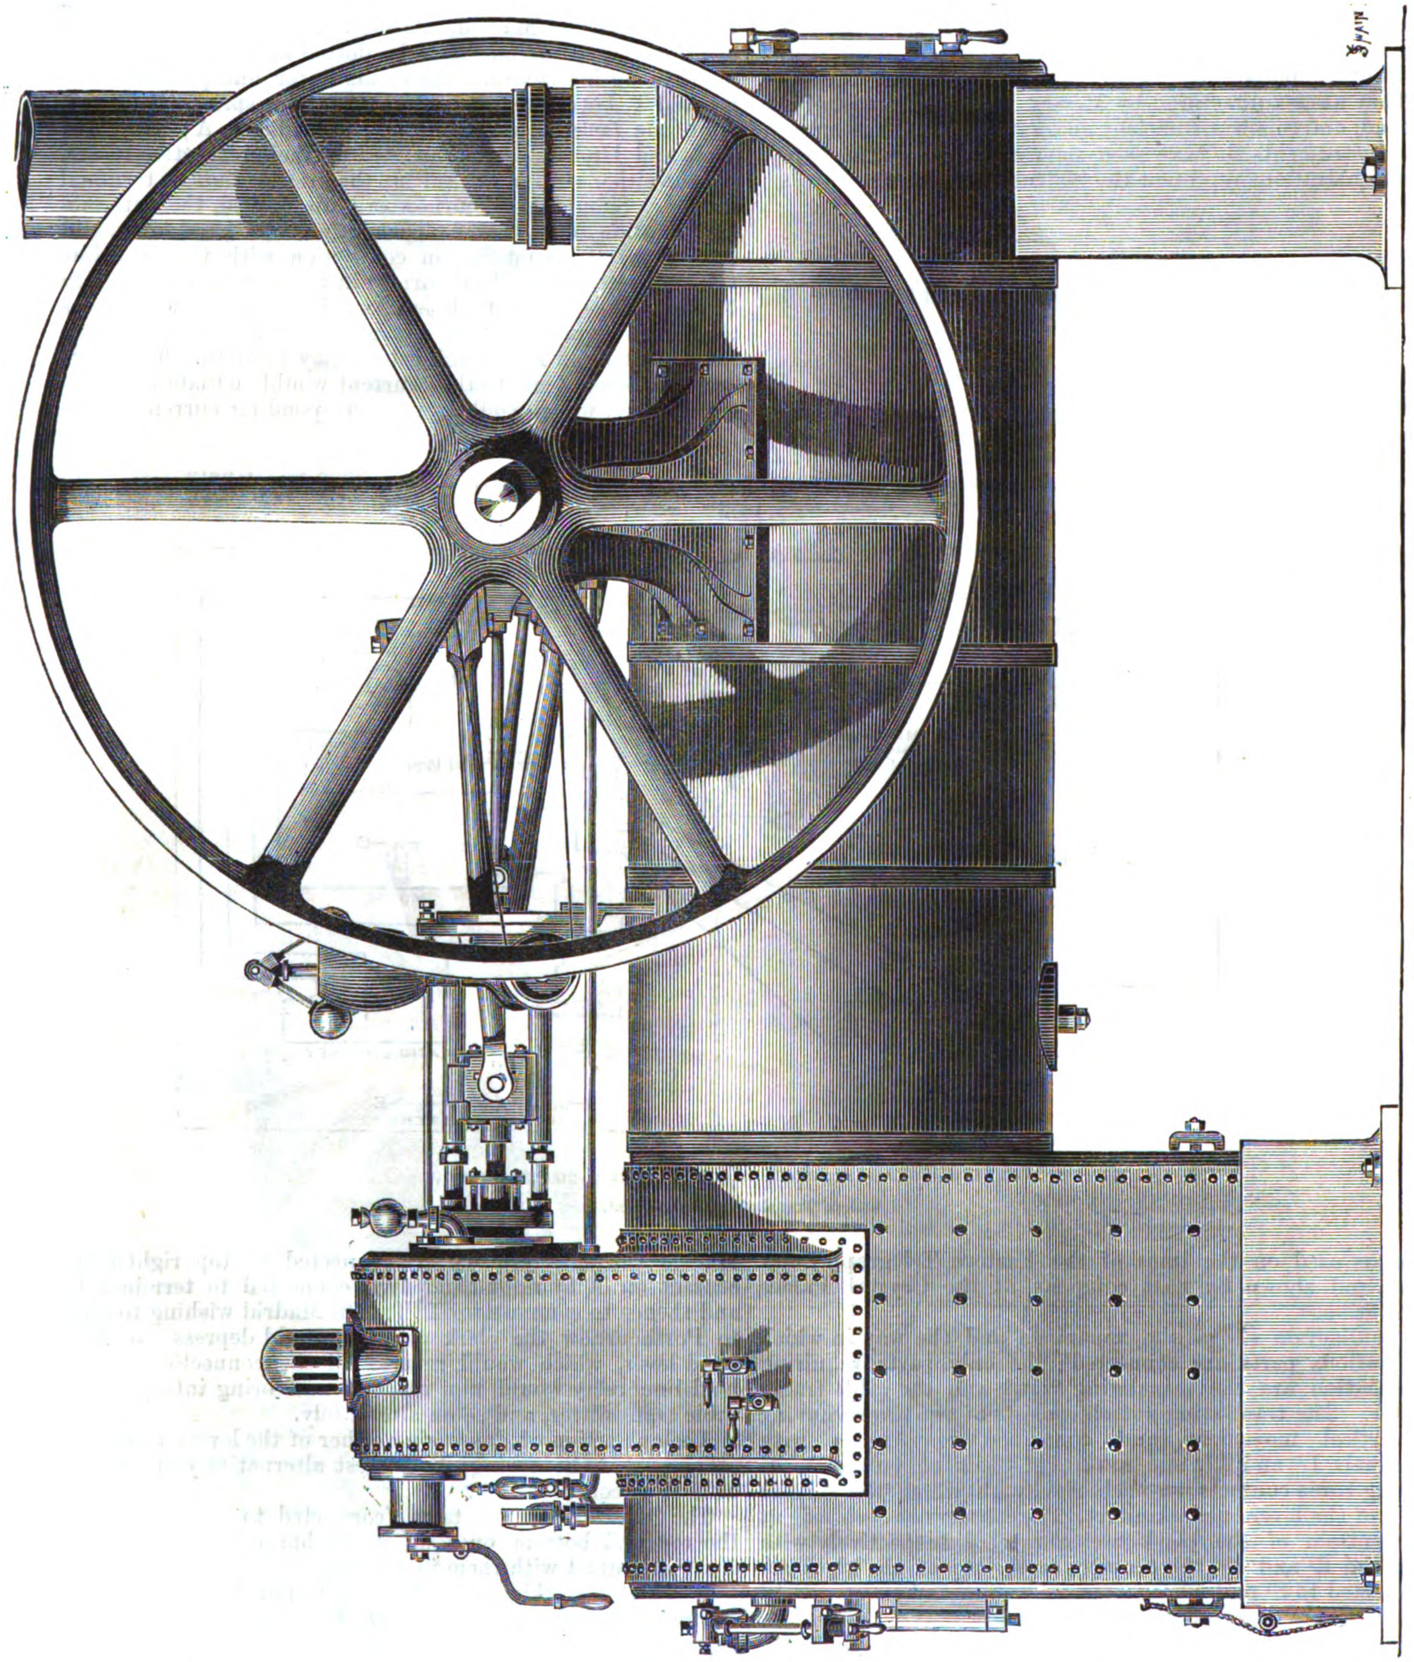
For direct working with Vigo to terminal stations plugs are inserted in the holes marked D. The connections are shown by the strong lines, the connections being as usual, except that the currents are sent into the cable by the cable transmitter actuated by a local battery connected to the cable key.

Hornsby's Portable Engine.

Among the many excellent engines in work at the Cryst-

Digitized by Google

Palace was the one which we now illustrate. It is a double cylinder portable engine by Messrs. Hornsby and Sons, of Grantham. The cylinders are 7·5in. diameter and 14in. stroke. The heating surface is 173 square feet, the fly-wheel is 7ft. in diameter, making 135 revolutions per minute. The engine was used for driving one 7 A Brush machine at about 750 revolutions per minute. The cylinders are fixed in a case of plate iron upon the top of the fire box, and the valve chests, cylinders, &c., are all perfectly jacketted by being enveloped in the boiler steam.



Hornsby's Portable Engine, for Driving Electric Light Machinery.

Cable Broken.—The island of Mull, Scotland, is at present cut off from telegraphic communication with the mainland, the cable being broken near the Mull shore.

Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 16th ult. amounted to £2,943.

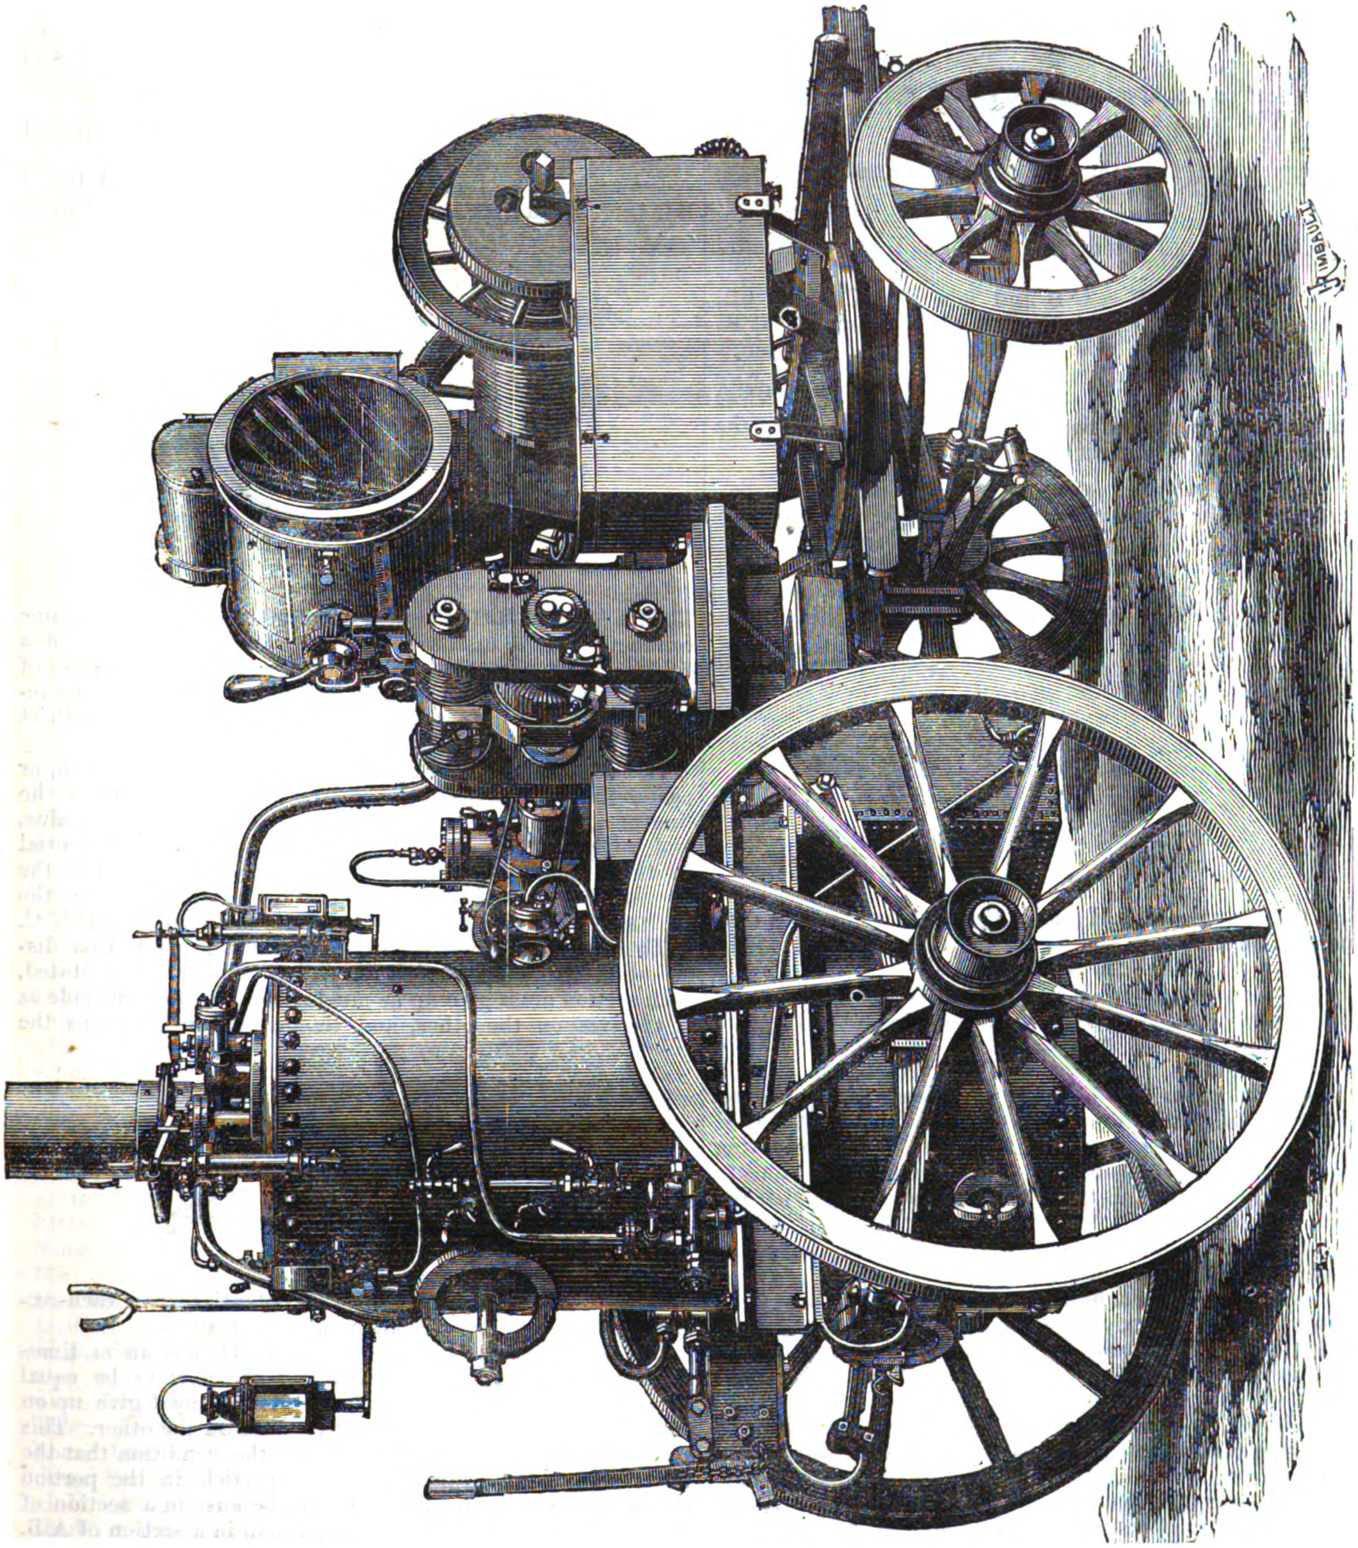
PORTABLE ELECTRIC LIGHT PLANT.

We herewith illustrate the portable electric light plant, as constructed by Messrs. Sautter, Lemonnier, and Co., of the Avenue de Suffren, Paris, for the French Government. It is intended to be used for military service, but can obviously be employed in many other directions. The illustration almost explains itself. The engine is a portable one, with a Gramme dynamo machine and regulator fitted on the same carriage. The dynamo is driven by a Brotherhood three-cylinder engine, which will be seen on the far side of the dynamo. Combined with the regulator there is a Mangin projector and a cell carrying a certain length of insulated conductor. The plant is intended by the French Government for use in fortifications, where its portability permits of its being rapidly shifted from point to point. It is remarkably compact, and, like all Messrs. Sautter and Lemonnier's work, of excellent construction. It was shown at the Paris Exhibition.



Sautter and Lemonnier's Portable Electric Light Plant.

THE (ELECTRIC) CONDUCTIVE AND INDUCTIVE CIRCUITS GEOMETRICALLY ILLUSTRATED.

BY F. C. WEBB, M.I.C.E.

(CONTINUED FROM PAGE 220., VOL. VIII.)

To prove the problem geometrically let A B (Fig. 9) as before represent the length of the circuit, to which its surface, inductive capacity, and resistance are proportional, and B M in the same manner the length of wire, with end M insulated, touching the circuit at B. Let C B be the potential (before the wire B is touched) on positive side of surface of generation and A F potential on negative side of same. Then before the wire B M is touched to the circuit the line of potential will be C F. It is required to find the point to which the potential at B will fall in order to make the quantity of electricity in B M (or B M multiplied by the new potential at B) equal to the quantity of electricity lost by the circuit (or A B multiplied by the old potential at B, minus the new potential at B).

Make M K and A N = C B and join N C K, which will consequently be parallel to A M. Join K A cutting B C at H. Then B H will be the new potential at B, and the parallelogram B H L M (representing the electricity in the wire B M) will be equal to the parallelogram E N C H, which is again equal to the parallelogram G F C H (representing the electricity lost by the circuit).

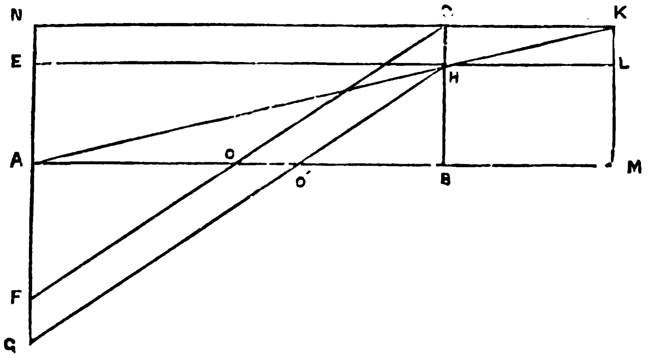

FIG. 9.

For the triangles K L H and H B A are similar, and, consequently, we have

$$KL : LH :: HB : AB$$

Consequently $LH \times HB = KL \times AB$,
but $LH = BM$, and $KL = CH$,
and $AB = EH$,
therefore $BM \times HB = CH \times EH$,

or the parallelogram B M L H, representing the quantity received by the wire B M, is equal to the parallelogram E H C N, which is equal to the parallelogram G F C H, representing the quantity lost by the circuit. H is therefore the point to which the potential at B must fall on the wire B M being brought into contact with the circuit at B. The problem is one of the gems in Ohm's celebrated paper, yet it is seldom alluded to in our text-books.*

We have here shown how a conductive body, having an inductive capacity, touching the circuit, alters the line of potential, but it will easily be seen that it follows from the same laws that the line of potential in an insulated circuit can, in a similar manner, be altered without actually touching the circuit to any conductor, by merely approaching the surrounding conductors to one particular part of the circuit, thus increasing the inductive capacity of that part which will immediately absorb electricity from the other parts, and thus alter the line of potential in the whole circuit.

We have thus far considered a circuit consisting of a single homogeneous conductor, of equal section throughout, at a single cross section of which exists a surface of excitation or generation where the electricity is generated and flows off equally from each side of this cross section. Such a circuit cannot exist in reality, but it is from such an imaginary ring that Ohm starts in his reasoning, and it is useful to bear in mind such a ring and the electrical state that would exist in it as leading up to the circuits formed of different conductors, liquid and solid, which do exist. Such a ring seen in perspective is represented in Fig. 10, where the thick line represents the ring. The cross section of excitation is at A, A P representing the positive potential immediately on one side of the cross section of excitation, and A N the negative potential immediately on the other side of the cross section of excitation, the line of potential being shown by the thin line P O N. The point O exactly half way round the ring being the point of no potential or the point where the negative and positive electricity recombine.

* This problem will be found treated of by me in the *Philosophical Magazine* for May, 1867.

We have now to consider the case of a circuit composed of several heterogeneous parts.

Let us suppose a circuit, composed of two parts, A B and B C (Fig. 11), having a single surface of excitation, A D, at A.

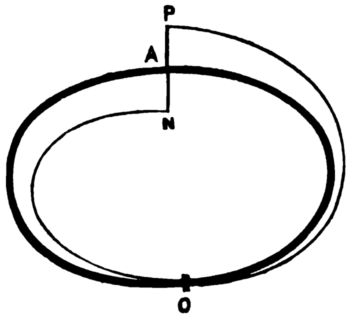

FIG. 10.

Then if A B and B C have the same section and are of the same conductivity, the case will be precisely similar to that of a circuit composed of a single conductor, A C, and the lines of potential will, if the circuit is touched to earth at C, be represented by a straight line, D E C, or if touched to earth at any other point, by some line parallel to D C.

If, however, the part B C is not of the same section, or conductivity as A B, then this constant inclination of the line of potential throughout the circuit no longer obtains, and we must seek for the position of the line of potential in these altered conditions of the case. For instance, the line of potential might, under certain conditions, assume the position D E′ C, or under other conditions the position D E″ C.

The first fundamental law determines, in fact, this distribution of the potential, for, as has already been stated, each section must give up as much electricity on one side as it receives on the other, and this condition occasions the

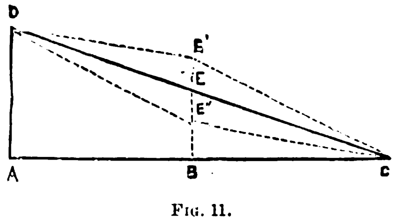

FIG. 11.

uniform inclination of the lines of potential when each section of the conductor is similar in every respect.

Let us now suppose that the part B C has an m times smaller section than A B; then for the flow to be equal throughout the whole circuit, each section must give up on one side as much electricity as it receives on the other. This state can evidently only exist under the condition that the electric transition from particle to particle in the portion B C is m times greater than in A B, because in a section of B C there are m times less particles than in a section of A B. But in order to produce this m times greater transition of the electricity from particle to particle, the differences of potential from particle to particle must, according to the first fundamental law, be m times greater than in the portion A B; or, in fact, the lines E′ C must sink m times more on equal portions of the line B C than D E′ does on equal portions of A B. Or, in fact, the line E C must have an m times greater inclination or dip than D E′. The lines of

Digitized by Google

potential will in this case, therefore, take a position represented by D E′ C.

From these considerations the following rule results:—*The dips of the lines of potential in different parts of a galvanic circuit composed of like substance are inversely as the sections of those parts.*

And in the same way:

When the parts A B and B C are of like section, but of material possessing different conductive powers, the dips of the lines of potential in each are inversely as the conductivities of those parts.

And, lastly, if the *two parts A B and B C have different sections, and are composed of materials of different conducting powers, the dips of the line of potential are inversely as the products of their sections and conductivities.*

Thus, if A B, being equal in length to B C, had double the section of B C, and was composed of a material having twice the conductivity, the dip of the line of potential in A B would be a quarter that in B C. Thus, D A — E′ B must equal one-fifth A D, or, in fact, E′ B must equal four-fifths of A D. If A B is not equal to B C, then the line of potential in B C *must in a distance equal to A B* sink exactly four times as much as the line of potential in A B does in A B.

If the part B C, on the contrary, had twice the section and twice the conductivity of A B, then the line from A to B would be steeper than that in B C, as shown by the line A E″ C.

In the same way, if we have a galvanic circuit composed of several different parts, the dips of the line of potential in each part will be inversely proportional to the products of their conductivities and sections.

Thunderstorms.—Heavy thunderstorms are reported as having taken place in various parts of the country in the latter part of last, and the early part of this week, accompanied in some instances by damage to property and loss of life. At the village of Llandyssil, in Carmarthenshire, on Monday, a number of cows were killed by lightning.—A Durham on the preceding Friday, during a heavy thunderstorm, the lightning struck a trap let into the cavity of the trench by which the telegraphic wires are carried up Silver-street. The trap consisted of a block of stone with an iron frame, the latter half an inch thick. The stone, a foot and a-half long and weighing about a half hundredweight, was thrown several feet into the air and smashed, whilst the iron framework was torn off and twisted out of all shape.—At a church in Ormskirk, near Liverpool, on Sunday, during evening service, the congregation were terrified by a sudden report and flash, and what appeared like a ball of fire passed through the church from the north-east. A panic ensued for a short time, but it was allayed by the vicar and curate, when it was found that no one was hurt. Subsequent examination proved that the lightning had struck the steeple, shattering some of the stonework inside, but leaving very little trace outside.—At Runcorn, also, near Liverpool, a house was struck, the lightning making a large hole in the outer wall, passing into the room, and damaging the window casing, but otherwise doing no damage.—At Dalkeith, in Scotland, on Saturday, the roof of the High School was struck and considerably damaged, as also was one of the chimney stacks.—At Dysart, on the same day, the lightning struck the chimney of the Victoria Linen Works, Sinclairtown.—At Sirenhill, in the Stonehouse District, Scotland, on Saturday, the lightning passed down the chimney of a house, knocking over a woman and child sitting by the fire-place, but not seriously hurting them; a man walking on the road at the same place was also knocked down, but though shaken, not otherwise hurt. The same storm seems to have visited Keith, where a valuable horse belonging to Mr. Mitchell, of Cairnie, was killed; the animal had been standing by a wire fence, and it is supposed that the lightning travelled along the fence.—At Selkirk the telegraph instruments were put out of gear by having their coils fused, and, consequently, telegraphic communication was interrupted for six hours.

CORRESPONDENCE.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I know nothing of Mr. Harbord's person or his belongings, therefore his insinuation of my having used "personalities" falls to the ground. The extraordinary nature of his first letter of denials unsupported by proof, or the possibility of proof, certainly entitled me to note that it did not require a wise man to write it; and his second letter to you is still void of any evidence that he really has any practical knowledge about electricity, while it displays a great deal of slipperiness. He attempts to institute a parallelism between the human voice passing through a window and electricity passing through the glass of a Leyden jar. Windows, as usually constructed, are not air tight. Every man of common scientific attainments knows that sound cannot pass where there is no air. It cannot pass through a vacuum that electricity can pass through. There is no true parallelism between the two cases. Mr. Harbord was either ignorant of the foregoing facts, or if not, he instituted the attempted parallelism to evade answering my question about electricity, which if he had answered, his answer would have afforded evidence that assertions in his first letter are not true.

The contents of his first letter indicate that he was ignorant of the fact that electricity passes through glass. In his second letter he admits that electricity passes through glass, but asserts "The glass of Mr. Johnstone's jar is non-conducting." What right has he to make such an assertion when he has no means of proving the truth of it, and when the assertion is in direct contradiction to the experimental proofs which I gave in my letter, page 61, that the glass of the Leyden jar did conduct electricity up to the moment that the jar became fully charged internally with electricity, and then the glass ceased to conduct the electricity, a discovery which is new in the science of electricity and gives us the means of knowing the true theory of the action of the Leyden jar.

Mr. H. denies that he believes in two electricities or even in one electricity, and "recognises only a figure of speech conveying the idea of an active agent producing certain effects;" yet, after all, he writes about the charge of a Leyden jar being "not retained because it is neutralised by reunion through or over the surface of the glass." Now this something which can reunite must have been previously separated into parts, proving that Mr. Harbord has in his mind's eye something more tangible than "a figure of speech;" but he won't come out with the information, as it would be tantamount to answering the question I put to him about electricity, a step which would result in showing the inconsistency of his writings.

If the glass of which a given Leyden jar is made be an absolute non-conductor of electricity, this jar virtually would be the same as a Leyden jar which is perfectly insulated. Now we know by practical experience, not only by my experiments, but by the experiments of others, that a Leyden jar which is perfectly insulated cannot receive a charge of electricity, hence we know that the glass of every ordinary good working Leyden jar must be to some extent a conductor of electricity. My experiments have proved that the glass of every efficient Leyden jar does allow electricity to pass through it to a large extent at the commencement of charging, but growing less and less in the amount of electricity passing through the glass as the charging proceeds up till the time the jar is fully charged with electricity, and then the passage of the electricity through the glass stops. It was the discovery of these facts which enabled me with certainty to announce *that static induction is a myth*, whether its supposed origin was supported by Faraday's theory of two forces or Mr. Harbord's theory of "a divisable figure of speech." If Mr. Harbord writes another letter to you, and if it does not contain a plain statement of the action which takes place when a Leyden jar is charged and discharged, I shall not answer his letter.—Yours, &c., James Johnstone.

SIXPENNY TELEGRAMS.

Though disappointed at the reception accorded by the Government to their motion, the advocates of sixpenny telegrams, both in and out of Parliament, have reason to be satisfied with the result of the division which followed. When as many as seventy-seven members can be induced to vote against the Government on a question of this sort, we may be sure that it is coming rapidly within the sphere of practical politics. We may concede this much in respect to the resolution of last Monday evening, which was rejected only by a majority of seventy-one. It would be wrong, however, to attach too much significance to the numbers. Something is to be gained in popularity by voting even for an abstract resolution; and as nothing can possibly come of it if the Government are so minded, there are always plenty of members ready to make capital out of the opportunity. Sixpenny telegrams would be very nice; we cannot have them—but we can vote for them. To get them would seriously injure the revenue; to go into the lobby for them injures nobody.

Some such reasoning as this, we imagine, must have actuated the gentlemen who consented to follow Mr. Cameron despite the explicit declarations of both the Postmaster-General and Mr. Gladstone that the object of his resolution could not be conceded. Perhaps, too, the wording of it had something to do with the voting. The resolution ran as follows: "That the working of the Postal Telegraph service with a view to the realisation of profit involved a tax upon the use of telegrams; that any such tax is inexpedient; and that the profit derived from the service is now such that the charge for inland telegrams should be reduced." Anybody could vote for the two first clauses of this resolution, and as to the third, in affirming what was not strictly true, its supporters probably thought they were helping to make it true. And no doubt they were; for if any considerable number of persons insist that there is now a profit on the service capable of being utilised in a certain way, when it can be shown that there is no such profit, the force of their convictions when the profit really does arise will be irresistible. We may say, therefore, that a reduced tariff for inland telegrams is one very big stride nearer, though it will not be upon us yet awhile.

The arguments in favour of the reduction were as usual of the meagrest description. The figures adduced by the mover and seconder of the resolutions were shown to be inaccurate or fallacious, and the main reasons in support of it are embodied in the resolution itself. Working the postal telegraph for profit does undoubtedly involve a tax upon the use of telegrams, just as working the Custom House for profit involves a tax upon the use of commodities. That the Telegraphs and the Post Office are supposed not to be worked for profit, whilst in such departments as the Customs and the Excise profit forms the primary object, is a mere accident. The Government taxes locomotion in several different ways, and that it should refrain from taxing communication is by no means an obvious proposition. Such a tax is inexpedient says the member for Glasgow; but it all depends on whether the proceeds are wanted. If they are wanted, it would be difficult to find a source of revenue less objectionable than this of the telegraphs. It taxes precisely the people who profit by it—that is to say the people who use it; and this is a merit which can be claimed by only a very few national imposts. Mr. Gladstone, so far as we can gather from the brief report of his speech, held to the doctrine that profits derived from the telegraph service were legitimate sources of revenue. "When," he said, "the revenue"—meaning, we suppose, the national revenue—"is in such a flourishing state that considerable sums were at the public disposal, the charge upon telegrams would come in just comparison with other claims upon the Exchequer." In other words when the Treasury can afford to forego the profit, such as it is, at present accruing from telegraph business they will consider the claims of the customer to a remission of charges. This to our thinking effectually disposes of the assumption that a tax upon telegrams in the form of a slightly excessive charge over prime cost is of itself necessarily inequitable or inexpedient.

The strongest arguments in favour of a reduced tariff were urged by the Postmaster-General, who, though unable at present to establish it, is evidently in favour of cheaper telegraphy. To Mr. Fawcett the fact that a telegram can be sent between the United Kingdom and Belgium, or France, for less money than from one part of London to another is a striking anomaly. No doubt it is; but the anomaly is not confined to this country, nor is it so illogical as it appears at first sight. The word rate and the message rate are two different things. For international telegraphy the former works satisfactorily, and rules very cheaply indeed in certain cases; but it is not a uniform rate in the ordinary meaning of the term, and so long as uniformity prevails for inland telegraphy, the international system will occasionally seem the cheaper. And this is as true of continental countries as of the United Kingdom. Neither is there anything so very outrageous in the

Digitized by Google

relative charges of the two systems. In point of actual expense, as well as of labour incurred in the despatch of messages, Paris and Brussels are nearer to England than are some parts of London to its suburbs. The truth, however, is, all such comparisons are deceptive, and are capable of proving almost anything. In framing our inland tariff we are guided by financial expediency, and are not to be frightened by anomalies.

We can take no exception to Mr. Fawcett's calculations as to the prospective possibilities of reducing the tariff based upon the average growth of the receipts. The loss that would be sustained were the alteration to take place at once is, we think, rather under than overstated; and we certainly consider the estimated time necessary for recovery after a loss amounting to nearly half the present net revenue was far too short. The tendency would be to reduce the average charge per telegram to its minimum, namely 6d., especially if the promoters of the scheme are sincere in their professions of expecting to make the sixpenny rate popular. The average amount received now for each telegram is only a halfpenny in excess of the minimum rate. The authority on which the Postmaster-General has relied for his calculations estimates the average price paid for each telegram, with a ½d. per word rate, and a minimum charge of 6d., would amount to 10d. We should ourselves be inclined to estimate it rather at something under 8d. An average reduction of 2½d. per telegram would, we fear, satisfy nobody; and, unless the "lower and middle classes," of whom Mr. Fawcett spoke in such touching terms as being virtually prohibited from using the present tariff, came to the rescue of the new in a benevolent and liberal spirit, the estimated loss would be far greater than we are given to suppose. For our part we do not believe in the lower classes sending telegrams for sixpence, nor in the middle classes sending more for sixpence than they do now for a shilling. What we do believe is that people who use the telegraph now would use it more largely if the cost were reduced, and that they would take particular care to reduce the cost as far as possible. This, of course, means that the revenue, instead of falling less than 20 per cent., would drop by something over 30 per cent., and that the process of recovery would be proportionately delayed.

ELECTRICAL ACCUMULATORS OR SECONDARY BATTERIES.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

No. IV.

(CONTINUED FROM PAGE 131.)

So far we have investigated the amount of chemical action in a Faure cell, when a given current is passed through it; but though this is important it is by no means all that we want to know, for the same chemical action exactly will go on in every cell through which the same current is driven, and the chemical work which a given current can do is, therefore, essentially unlimited. But, of course, the more cells we have in series, the more driving power—or electromotive force—do we require to send the current through them; and the chemical work that can be done by a given current generator is determined, therefore, by its available electromotive force and current strength conjointly. In this respect chemical work is precisely in the condition of every other form of work, and, in fact, it cannot be otherwise.

Consider now, as our source of current, a dynamo-machine driven with the horse-power P. Of this power some is wasted in friction and in churning the air; another portion is spent in warming the exciting magnets and armature, while the remainder, which we will call p, is available for maintaining the current through the external circuit. What fraction p is of P depends upon the perfection of the dynamo, and, indeed, the ratio $\frac{p}{P}$ may be called its efficiency. We may, perhaps, surmise that a probable value for this ratio is as much as $\frac{3}{4}$, but it is not likely to be more. To measure p we have only to masure the electromotive force in volts between the terminals of the dynamo and the currents in Ampères which it is at the same time producing in the whole outer circuit, multiply the two together and divide by 746. We will, therefore, take p as a known quantity.

Now take N Faure cells and arrange them, n in series and m abreast, so that they are equivalent to n cells, each m times the size of a single one. Of course $m\,n = N$. Let the resistance of each cell with its connecting wire be r ohms—the resistance of the leading cables need hardly be taken into account if they are thick enough to keep cool—then the resistance of the combination of cells is $\frac{n\,r}{m}$ ohms.

To drive a current of C Ampères through this resistance would require an electromotive force $\frac{n\,r}{m}$ C volts, which we may write $n\,r\,c$, if we put c for the current passing through each of the m series of cells. But this electromotive force is not enough to maintain the current for more than an instant; for directly the cells begin to charge they each exert an opposition force e, which must be overcome. This opposition e may or may not vary during charging, but it probably does not vary very much after the first hour or so, and it may be considered as not far off 2½ volts. It can be measured by connecting an electrometer to the terminals of a charged cell momentarily disconnected from the charging circuit. No time must be lost in taking this measure, or its value will diminish, and if the cell is short-circuited it falls off rapidly—probably because of the consumption of the hydrogen alloyed with the lead. It is its maximum value which is active in opposing the charging current, and this it is which we agree to call e in volts. The whole set of cells will offer an opposition force $n\,e$ volts.

If the cells are not uniform we must determine the *average* values of e and r, but there is every possible reason for turning out the cells from the manufactory as uniform as they can possibly be made, and afterwards keeping them uniform by subjecting them to precisely similar treatment. Hence the practice of replenishing the power of a working battery by occasionally adding an instalment of fresh cells is not to be approved on a large scale, unless it is carried on with regularity, a fresh one being put on at one end and a comparatively worn-out one simultaneously taken off at the other by some automatic time-keeper.

It is well known in ordinary voltaic batteries that if any of the cells are different from the others in any way, we get all the disadvantages which such difference may cause, and scarcely any of the advantages; in other words, one extra good cell in a series of poor ones is lost, and its effect swamped; while a single bad one among good ones chokes the lot. It is only like the links of a chain after all. Any difference—whether in size, or weight of lead, or closeness of plates, or time of charging, or of standing, or of discharging, or any temporary short circuiting of one cell more than of others—if it can produce harm it will, but if it tries to do good it can't. Hence every difference should be avoided.

Well, we were going to write down the E M F necessary to force the current C through each of the m series into which we have supposed our cells to be arranged while charging, and it is

$$E = n\,e + n\,r\,c$$

the first term overcomes the opposition electromotive forces, the second drives the current against the given resistance.

The whole energy expended per second is proportional to E and to the whole strength of current C, or $m\,c$, and is

$$E\,C = m\,n\,e\,c + m\,n\,r\,c^2$$

The first term represents the useful work done, or the

* We reprint these excellent articles from the *Engineer*.

Digitized by Google

energy expended in overcoming chemical affinities, and in storing the current; or at least it represents this on the hypothesis that all the chemical substances decomposed assist the storage by being ready to recombine and drive the current back again whenever called upon to do so, and not before. If the cells are allowed to evolve gas while charging, or to stand a long time after charging, these conditions are not fulfilled, and some of the $m\,n\,e\,c$ is lost. Hence in saying that $m\,n\,e\,c$ represents the useful work, one means that it does so under the most favourable circumstances, or that it represents its maximum value.

The second term $m\,n\,r\,c^2$ is certainly all wasted and goes to warm the cells. The proportion between the waste and the useful is therefore $\frac{r\,c}{e}$; and this shows the great desirability of keeping the charging current c weak, as well as for having the cells large and of low resistance. The horse-power available as current we have supposed to be p, and $p = \frac{\text{E C}}{746}$; hence we may write the foregoing equation thus (remembering that $m\,n = \text{N}$):—

$$\text{N}\,c = \frac{746\,p}{e + r\,c}.$$

This represents the total amount of chemical action going on in all the cells put together, for the current c is passing through each, and chemical action proportional to c is going on in each, therefore the total chemical action is N c. Looking at what N c is equal to, we observe that p is fixed and e is beyond our control; so again we perceive that the only way of getting the most effect at the least cost is to keep $r\,e$ small. Now the resistance of a large Faure cell and connections need not exceed, I suppose, ·002 of an ohm, and the charging current sent through it may be kept as low as 4 or 5 Ampères if desired; hence, as the value of e is 2·5 about, it is quite possible to make $r\,c$ almost wholly negligible compared with e. We shall thus get out of the given horse-power the greatest amount of chemical action per second that we possibly can, viz.:—

$$\text{N}\,c = 746\,\frac{p}{e}$$
$$= 300\,p \text{ say.}$$

The equations of last week, expressing the amount of total decomposition on both sides of a Faure cell when a given current is passed through it, may be now modified to express the decomposition produced in a whole set of similar cells arranged economically and subjected to the utilised horse-power p for T hours, by simply writing in those equations 300 p T instead of C T.

As far as here appears, the number of cells does not signify, for if more cells are used less will be done in each, and conversely. But we have just seen how important it is to keep c small, that is, to charge with a very low strength of current; hence the more cells charged at once the better. It seems difficult to use too many. The limit in series is reached when $n\,e$ is nearly equal to the highest possible electromotive force of the shunt dynamo—that is, the number n must not exceed two-fifths of the maximum electromotive force available, expressed in volts. But it may be nearly as great as this with advantage. There seems no limit to m, the number of cells that may be joined up in multiple arc, and apparently the more the better. But the "lead" wires and the armature of the dynamo must be of very low resistance, or they will get heated if m is very large, even though c, the current through each set of cells, is small. Edison's bar armatures seem just the thing therefore, or some of those machines which are made for electro-plating purposes. The wire on the field magnets should be very long, so as to magnetise them strongly without shunting off too strong a current, even though it is driven with the highest available electromotive force.

The highest available electromotive force is the difference of potential between the terminals of the shunt dynamo when they are disconnected from the external circuit, so that the whole of the current produced in the armature passes through the field magnets. There must be some connection between the resistance of the wire on the field magnets, and on the armature, and the number of cells which will give the most economical result, though it is not a relation that is obvious to common sense; but it can no doubt be worked out if we set to it, and I will try next week. Meanwhile, let us put in a convenient practical form part of the result of this week's article, viz., that if the best arrangement is adopted in every way, no waste being allowed, and no secondary or useless chemical action permitted, the total amount of any substance of "atomic weight" w and atomicity k that can be decomposed or liberated, as the case may be, by p horse-power, utilised as current in any number of cells, each of maximum electromotive force e, is

$$\frac{746\,p}{e} \cdot \frac{w}{12000\,k} \text{ pounds per hour,}$$

which becomes for Faure cells, whose e is $2\frac{1}{2}$ volts

$$\frac{p}{40} \cdot \frac{w}{k} \text{ pounds per hour.}$$

For instance, 2·8 p pounds of lithage can be peroxidised, and also reduced, per hour, by the horse-power p applied to this purpose and to nothing else. Of minium the amounts are 2·1 p reduced, and 4·2 p peroxidised; that is, 6·3 p pounds of minium may be acted on altogether under the most favourable circumstances. Thus, if 5 horse-power are utilised as current, 31·5lb. may be acted on in an hour, or a ton in 71 hours. To form 120 cells, each containing 28lb. of minium properly distributed between the two plates, cannot take less than T hours, where $6{\cdot}3\,p\,\text{T} = 28 \times 120$; which for $p = 5$ gives T = 106. But if the cells contain 14lb. of minium on each plate they will take longer, viz., at the very least $\frac{100}{p}$ hours.

POSTAL TELEGRAPH TARIFFS.

In the House of Commons on Monday the question of a reduction in the rates charged by the Post Office for inland telegrams came up, and elicited an interesting statement from Mr. Fawcett, the Postmaster-General.

We give the report of the proceedings as it appeared in *The Times* of Tuesday last:—

"Dr. CAMERON called attention to the rates charged by the Post Office for the transmission of inland telegrams, and stated that the principles on which the charge for telegrams should be based were rightly explained by the Postmaster-General to be two. In the first place, any undercharge was to be deprecated, as involving the taxation of the community for the benefit of those persons who sent telegrams; and, secondly, any overcharge was to be avoided, as resulting in the taxation of the senders of telegrams for the benefit of the community. The earnings made by the postal telegraph system had gradually risen, until they amounted to £540,000 per annum, a sum sufficient not only to pay a 3 per cent. dividend on the capital employed, but also to provide a surplus of £220,000, representing a profit to the tax-paying community made at the expense of the senders of telegrams. It had been asserted that the adoption of a 6d. minimum charge for telegrams would lead to a loss to the Post Office of £167,000 per annum. But with a surplus revenue of £180,000 per annum the Post Office could afford to try the experiment, and he was satisfied that before long the increase in the number of telegrams would convert any loss that might be sustained by the reduction of charge into a profit. A tax upon telegrams was a tax upon commerce, and he, therefore, asked the House to pronounce that tax inexpedient. He begged to move that 'The working of the Postal Telegraph service with a view to the realisation of profit involved a tax upon the use of telegrams, that any such tax is inexpedient, and that the profit derived from the service is now such that the charge for inland telegrams should be reduced.'

"Mr. MONK had great pleasure in seconding the resolution. On several occasions within the past few months he had been in communication with the right hon. gentleman with regard to a reduction in the rate, not only of inland but also of foreign telegrams, and the replies of the right hon. gentleman had on the whole been of a very encouraging nature. The subject was one in which the various chambers of commerce throughout the country had taken a very great interest, and it was felt that a

Digitized by Google

reduction in the cost of telegrams would be a very great boon to the commercial community. In these circumstances, he hoped that no great opposition would be offered by Her Majesty's Government to a proposal for an early reduction in the charge for telegrams, if not to 6d., at least to 9d.

"Mr. Fawcett would endeavour to deal very frankly with this very important question. He fully admitted that the arguments in favour of a reduction in the charge for telegrams were very strong. It was undoubtedly the case at the present time that under the international rates which had been lately settled, it was possible to send a telegram from any part of England to any part of Belgium, or from any part of the United Kingdom to any part of France at a less cost than was incurred in sending a telegraphic message from one part of London or of Liverpool to the other. The reason for that was that under the special rate agreed upon between England and Belgium telegraphic messages were sent at the rate of 2d. a word, and under that agreed upon between England and France they were sent at the rate of 2½d. a word. It was not unusual for a telegram sent under those scales to consist of an address of three words and a single word, such as 'better,' 'come,' or 'worse,' and such a message could be sent to Belgium for 8d. and to France for 10d. He was also free to confess that in view of the number of telegraph stations in the United Kingdom the number of messages sent was not as large as might have been expected. The number of telegrams sent each year was about 25,000,000. That gave a weekly average of about 480,000, and a daily average of about 80,000. Considering that there were 5,000 stations, he did not think that 80,000 was a large amount per day, and there was no other conclusion to arrive at than that the present 1s. charge was virtually prohibitory, not only to the working classes, but to many of the middle classes also. He hoped the House would think that he had stated the case in favour of a reduction in the price of telegrams clearly and unreservedly. He was further prepared to admit that if the price of telegrams were reduced there would probably be a large increase in the amount of business. But his hon. friend had thrown out a suggestion with which he could not quite agree. He contended that the reduction in price might be made in bits by reducing the price for local telegrams only. He thought, however, that it would be a most serious thing were they to infringe upon the principle which seemed to regulate the Post Office system—namely, uniformity of charge. In France, and, he believed in some other Continental countries, they had what were known as express telegrams —that was that, by paying an extra fee, the telegram had priority over ordinary ones. As regarded that system, he could only say that as long as he had the administration of the Post Office he would strenuously oppose its introduction. It would introduce an unfair partiality, and he thought that the system should be resisted as being a most undesirable one. While agreeing with much that had fallen from his hon. friend he could not accept his motion as it stood, because it was opposed to facts as they existed at the present time. He was prepared to say then, as he said when he received a deputation on the subject, that the question was worthy of the consideration of the Chancellor of the Exchequer whether telegrams were a desirable means of taxation. But his hon. friend had assumed that at the present time a profit was being made upon this service. It would be his painful duty to show that the conclusion at which his hon. friend had arrived was not applicable to the present state of things. His hon. friend said that the telegraph revenue calculated on commercial principles showed a regular growth since 1876 amounting to about £23,000 per annum, the total for the year 1880-81 being £440,000. His hon. friend concluded from that that the revenue for 1881-82 would be about £500,000. That would be so undoubtedly if the revenue continued to increase, but, unfortunately, a considerable decrease was anticipated during the present year owing to the following facts:—The House would remember how last Session he was pressed by hon. members on both sides to increase the pay of the telegraph *employés*. He had granted an increase to those *employés*, which had cost the Department about £80,000 per annum. That amount must, of course, be added to the cost of the telegraph service, and the effect would be that, instead of £512,000 revenue for this year, the revenue would probably not exceed £400,000. He was aware that complaints had been made by the telegraph *employés* that the increase accorded to them was very small and that it was worse than nothing. All he could say was that, if they considered a charge of £80,000 a year on the public funds worse than nothing, he deeply regretted having made a sacrifice of public money to them. His hon. friend had stated that the reduction to 6d. telegrams would, probably, cost the revenue about £170,000. Those were the figures he had previously given and he was prepared to abide by them. He would show the House how that sum was arrived at. The average amount now received from each telegram was 1s. 0½d. The cost was about 9d. The profit was thus about 3½d.; and 25,000,000 telegrams at 3½d. amounted to £364,000. The gentleman who was at the head of the telegraphic department of the Post Office had informed him that if telegrams were reduced to ½d. per word, with a minimum charge of 6d., each telegram would be charged on the average 10d. and the cost would be 8½d. A gentleman had calculated that there would, probably, be 30,000,000 of telegrams instead of 25,000,000. Each telegram would then bring a profit of 1½d., and the net revenue would be £187,000, showing a loss of £177,000. On the other hand, he was bound to admit that there were many high authorities who did not estimate that the loss would be so great as he had just said. But it was absolutely impossible to foresee what would be the result of sixpenny telegrams. It was well to remember that the greatest of all postal reforms—the introduction of the penny postage—was not at first a financial success. Experienced officials had carefully looked into the question and informed him that it was more than sixteen years after the introduction of the penny postage before the revenue reached its former amount. Great, therefore, as might be the after financial results, and the advantage conferred immediately upon the public, it by no means followed that loss would not be incurred by the adoption of such a reform as was advocated by his hon. friend. The result arrived at was that the revenue from inland messages would be reduced by £177,000. If the present net revenue was taken at £400,000, the future revenue would be £223,000. The capital expended in the telegraphic service was about ten and a half millions. Interest on that sum at 3 per cent. would be about £320,000. Thus, instead of the telegraph bringing large profits as his hon. friend had said, there would be a deficit of £100,000. Besides he had taken the interest at the lowest amount —3 per cent. But the result would be still less satisfactory if the interest were reckoned at 3¼ per cent. as it really ought to be reckoned. It was, however, desirable to state that although that would be the immediate financial result, he believed that with sixpenny telegrams the revenue would steadily improve. The head of the telegraph department had come to the conclusion that at the end of four years the revenue from the telegraph would have regained its present position. The question, therefore, to be considered by the Chancellor of the Exchequer, that House, and the country was whether for the sake of the great advantages which he believed would result to the community from the lowering of the price of telegrams, it was worth while to sacrifice for the first year £177,000, for the second year it might be £140,000, the third year perhaps £100,000, and at the end of the fourth year, perhaps nothing at all. He hoped he had stated the case clearly. It was often asked by the public Press and by Chambers of Commerce why the Postmaster-General did not introduce sixpenny telegrams. His answer was, 'Where is the money to come from?' On the other hand, he was often asked to raise the wages of telegraph *employés*. But he would ask hon. members to remember that they could not eat their cake and have it. He could only say that the best way for hon. members on both sides of the House to bring about sixpenny telegrams was to strengthen the hands of the Government in carrying out their policy of economy. As for himself, nothing would give him greater pleasure than to receive a message from the Chancellor of the Exchequer that the finances of the country were in a condition to admit of the change proposed.

"Mr. R. Martin hoped that the Government would take into account the important bearing upon the question of telephonic communication, which in large towns was tending to supersede the telegraph.

"Dr. Cameron said that he should go to a division on the question of the expediency of taxing the country for the purpose of reducing the price of telegrams.

"Mr. Gladstone thought that the statement of his right hon. friend was clear and ingenuous. His right hon. friend had shown no bias against the principle of reduction in the price of telegrams, and had, in fact, been liberal in the expression of a general opinion in favour of the views expressed in the motion. He did not know that he should be disposed to go quite so far as his right hon. friend upon the question of taxation for the benefit of the telegraph service. No doubt no remission of taxation had been more advantage to the public than remissions on the means of communication. When the revenue was in such a flourishing state that considerable sums were at the public disposal the charge upon telegrams would come in just comparison with other claims upon the Exchequer. Further than that he could not go at the present moment.

"Mr. J. Howard hoped the Postmaster-General would signalise his tenure of office by the introduction of sixpenny telegrams.

"The House divided, when the numbers were—

TELEGRAPH CLERKS' CONFERENCE.

The annual Conference of the Postal Telegraph Clerks' Association, established in December, 1881, was held at Anderton's Hotel, Fleet-street, on Saturday last, Mr. Mulholland, of Manchester, in the chair. Delegates were present from all parts of England, Ireland, and Scotland.

The CHAIRMAN having briefly opened the conference, Mr. Crighton (Liverpool) submitted the following resolution:—"1. On behalf and at the desire of the postal telegraph clerks of the United Kingdom, this conference expresses its strong dissatisfaction at the inadequacy of the scheme of revision last year applied to their department, as well as at the unjust and partial manner of the application of that scheme, and its indignation that, while that scheme ostensibly confers benefits, however small, those benefits are throughout the service to a large extent nullified by the system of classification which is still retained, and in several important offices quite or more than counterbalanced by such retention in conjunction with an extended system of divided attendance which deprives members of the staff of about four additional hours daily." Prior to the revision, the speaker said, public opinion was almost unanimous in their favour, and Mr. Fawcett had therefore found it necessary to attempt some kind of investigation. With reference to the scheme which was the result of this investigation, the speaker said that one of their principal complaints had been that the salaries of telegraph clerks of eight or nine years' service was not in accordance with their responsibility. To remedy this, Mr. Fawcett gave two or three men a weekly increase of 16s. 6d., and ignored the claims of the main body of telegraph clerks. Ten per cent. of them received substantial promotion; but would it not have been far better, as a matter of economy and prudence, if Mr. Fawcett had given an immediate rise of 5s. to 35. per cent. of their number, rather than the greater rise which had been given to 10 per cent. The telegraph clerk of seven years' experience was worth at least £75 per annum, with a prospective maximum of £200 a year. In many offices the old first class at 44s. had been abolished, and 36s. had been substituted, and men who were at the top of the old second class had received a shilling rise, and were debarred from further advance; but even this small concession was modified by the retention of classification. In reference to Sunday duty, too, the scheme was inadequate, and the night-duty arrangements were to be condemned. Physically, socially, and intellectually they were very injurious. It was impossible to make any arrangements for mental culture, and it was felt that there should be some reduction of the hours of work, and not merely a quarter of an hour one day and half an hour another. In every respect where the revision was made its advantages were neutralised by classification and the new system of promotion. The number of superior appointments in the telegraph departments was not so large as the postal departments in most of the large towns. For example, in Liverpool the number of postal clerks was 183, for which there were fifty-eight superior appointments; while the number of telegraph clerks was 198, with only twenty superior appointments. He urged that they should have a parliamentary inquiry, to which Mr. Fawcett, who had already admitted their claims by his revision, could have no possible ground of objection.

Mr. CLARKSON (Newcastle-on-Tyne) said the staff which he represented had publicly expressed their dissatisfaction with the arrangements of Mr. Fawcett, and with the manner in which they had been applied. They objected to the disparity in the number of superior appointments compared with the number in the postal department, and to the provisions with regard to holidays, in which a change had been promised, but which change it was now announced could not be effected.

Mr. DELAHUNTY (Dublin) held that the only way in which they could hope to obtain redress was to obtain a Select Committee in the House of Commons to inquire into their grievances.

Mr. HEALD (Manchester) said that Mr. Fawcett had evidently valued the labour of telegraph clerks from the standpoint which he took with regard to the sorters. In talking with Mr. Cowen, the member for Newcastle-on-Tyne, the previous day, that gentleman had remarked that he might be able to do sorter's work, but he certainly was not qualified to do the work of the telegraph clerk. In that opinion Mr. Cowen was correct.

Mr. ROBINSON (York) said that the only thing they could do was to obtain a Select Committee. Petitions were in his opinion a farce, and they must, through the Press, the public, and Parliament, endeavour to get their grievances ventilated before a committee of the House.

Other delegates spoke to the same effect in support of the motion.

Mr. MORRIS, the general secretary, said he regarded the scheme of revision as totally inadequate, an inadequacy which was aggravated by the mode of its application. The Playfair Commission was expressly appointed to inquire into the mode of promotion adopted in the Civil Service. That Commission expressly reported against classification, and the telegraph clerks thought it hardly fair that in face of that report the postal authorities should retain the system of classification with regard to the services over which they had control. Classification, which meant that an expert of the second class should receive considerably less wages than a man in the first, who was not so facile at his business, and who must wait if he wanted promotion until a vacancy occurred in the first class, was in itself an evil, besides which the fact that the increases were small tended to aggravate the dissatisfaction with which classification was regarded. Combination had done something for them in the past, and it might be depended upon to do something for them in the future. All they asked for was impartial inquiry, and he believed that another year would enable them to congratulate themselves on having achieved a further improvement of their position.

Mr. HASLAM (Birmingham) raised an objection to the word "nullified" in the resolution, and it was accordingly modified as follows:—that "benefits would be to a large extent diminished."

The resolution as amended was then carried unanimously.

Mr. SCOTT (Liverpool) moved, "That the great pressure of public business in the House of Commons having rendered it impossible for Mr. Macliver to introduce his motion for the appointment of a Select Committee to inquire into the grievances of the telegraph clerks, this Conference, while heartily thanking him for his past efforts on their behalf, earnestly hopes that he will avail himself of the first favourable opportunity of taking the opinion of the House upon the subject."

Mr. BRIGHTON (Bristol) seconded the resolution, which was supported by other delegates.

Mr. LUCAS (Leicester) thought that it would be well to issue a circular which would put members in possession of the whole of the facts. At present members of Parliament had an insufficient knowledge of what were really their grievances.

Mr. HASLAM (Birmingham) fully agreed with the last-named delegate, and suggested that it would be an advantage if they made use of local political organisations. Of course, he granted that there was nothing political about their movement, but what he wanted was, that in their various districts they should endeavour to lend weight to their representations to members of Parliament by bringing in the aid of local political organisation wherever it could be obtained. There was one point on which he wished to lay stress, and he hoped the experience he had was common to them all. The Birmingham postmaster took a kindly interest in all his subordinates, and was really anxious to better their condition; but while he did not object to their meeting and discussing their grievances, he certainly did object to their putting their grievances before the local public through the Press, and thus committing a breach of that official discipline which was necessary to the good order and government of any public institution such as theirs, with its grave responsibilities. In conclusion, he hoped that they all would be loyal, while respectful and obedient, in the support of their claims—claims which he believed would be more in the public benefit than of the telegraph clerks themselves.

The resolution was then adopted in a somewhat modified form as follows:—"That this conference, being of opinion that an inquiry by a Select Committee of the House of Commons into the administration of the telegraph department is necessary in the best interests of the service, earnestly thanks Mr. Macliver, M.P., for his past efforts on their behalf, and hopes that he will avail himself of the first opportunity to take the opinion of the House upon the subject."

Mr. CLARKSON (Newcastle) then brought under consideration the propriety of taking before the law courts a test case by which to decide whether, under the Telegraphs Act (1868), pre-transfer clerks should be conceded the rights and privileges of clerks in the permanent Civil Service of the Crown.

After some discussion the following resolution was carried unanimously:—"That the pre-transfer clerks be recommended to memorialise the Postmaster-General, praying that they be conceded the rights and privileges of clerks in the permanent Civil Service of the Crown; and that, pending the decision of the Postmaster-General, further consideration as to legal action be referred to the central committee."

The attention of those present was then directed to the private affairs of their association, suggestions being put forward that they should register themselves as a friendly society, or trades union. The balance-sheet of the association, though it is but six months old, shows a balance of over £610.

THE MAGAZINES.—The *Nineteenth Century* for July contains an article on "Electric Light and Force," by the Right Hon. Viscount Bury.

LEGAL.

LONDON AND GLOBE TELEPHONE COMPANY v. UNITED TELEPHONE COMPANY.

This case came before Mr. Justice Fry in the Chancery Division of the High Court of Justice on Thursday week. The plaintiffs are the assignees of Hunnings's patent transmitter. The defendants are the assignees of both Bell and Edison's patents for telephones in this country. This was a motion to restrain the defendants from continuing the publication of printed statements in the nature of a libel on the plaintiffs' patents. The statements complained of were parts of a notice printed on the inside of the cover of a pamphlet entitled "The United Telephone Company (Limited) list of subscribers to the Exchange system," and were in the following terms:—

"The United Telephone Company have been advised by eminent counsel that all forms of transmitters in which carbon is used in a free or powdered form—as, for instance, in the transmitters usually known as Moseley or Hunnings—and that all the so-called microphone transmitters, including those known as the Crossley and the Gower-Bell, are infringements of Mr. Edison's patent as amended by disclaimer." And "No form of magneto telephone, and no form of transmitter in which carbon or other equivalent substance is employed, whether known as Edison's, Moseley's, Hunnings's, Crossley's, Gower's, or any other name, can be manufactured, sold, supplied, or used in this country except under license from the United Telephone Company (Limited). Proceedings will be taken against persons infringing the company's patents and other rights as above set forth."

It will be remembered that in the recent case of the United Telephone Company *v.* Harrison, Cox, Walker, and Co., the plaintiffs, amongst other things, sought to restrain the defendants from making or selling Hunnings's transmitter, alleging that it was an infringement of Edison's patent. In his judgment, however, Mr. Justice Fry held that Edison's patent was void because he had claimed in the complete specification the phonograph, an instrument which Mr. Justice Fry did not consider to have been foreshadowed in a proper manner in the provisional specification.

It appeared from the evidence in the present case that, on the solicitor to the London and Globe Company complaining of the issue of the printed statement subsequent to the above-mentioned trial, the solicitors of the United Telephone Company had written to say that they had advised the defendants that the statements must be altered in accordance with the position of matters; that amended statements would appear in the next issue of the list of subscribers; and that in the meanwhile any copies in hand would not be sent out. Notwithstanding that undertaking, some copies were delivered to the persons who made inquiries at the United Telephone Company's offices, and this action was commenced.

The defendants put in evidence that the copies had been delivered without the knowledge and against the intention of the higher officials, that the remaining copies had since been locked up, and they would issue no more. Nevertheless, they defended the motion; in the first place,on the ground that there was no evidence of any damage to the plaintiffs having resulted from their negligence. In the next place, it was argued on their behalf that the statements were really matters of opinion, which they had a right to state, for the decision was under appeal, and that Lord Maclaren had, in an action brought in Scotland, upheld Edison's patent.

In giving judgment, Mr. Justice Fry said:—The questions which I have to determine in the present case are two. In the first place—Are the defendants acting honestly in insisting upon their right to issue the notice complained of? and, in the second place—Have the plaintiffs satisfied me that they are sustaining any injury from the publication of this notice?

The facts are these. The defendant company issued a notice in this form—"No form of magneto telephone, and no form of transmitter, in which carbon or any other equivalent substance is employed, whether known as Edison's, Moseley's, Hunnings's, Crossley's, Gower's, or by any other name, can be manufactured, sold, supplied, or used in this country, except under license from the United Telephone Company (Limited). Proceedings will be taken against persons infringing the company's patent and other rights as above set forth." I determined in the action which was before me that Hunnings's patent could be manufactured, sold, supplied, and used in this country without a license from the United Telephone Company. I, therefore, rightly or wrongly, determined the very opposite of the proposition which the defendants put forward. I am perfectly alive to the very great probability that my decision may be wrong. I know it is at variance with the decision of an eminent judge in Scotland; but, however great my sense of doubt may be as to the ultimate decision of the case, I must bear in mind that I am a competent judge to decide a case, and as long as my decision stands I am bound to act upon it, just in the same way as I should feel myself bound to act on the decision of any judge sitting in any of the other courts of this country. I cannot, on any grounds of modesty, refuse to act upon my own decision. That being so, I take it, the defendants are now alleging the very opposite of that which a competent court has decided to be the case. It is suggested that they are doing this *bonâ fide.* Now, how stands the matter as to *bonâ fides*?

In May, the present plaintiffs complained of the circular, and the solicitors of the defendants, Messrs. Waterhouse and Winterbotham, informed the plaintiffs' solicitor—"Immediately after the decision of Mr. Justice Fry, we informed the secretary that it would be necessary to make alterations in the notice respecting infringements in accordance with the present position of matters, and these amended statements will appear in the next issue. In the meantime any copies of the existing list which remain in the company's hands will not be sent out." Nothing could be more straightforward or proper on their part. They gave the very best advice to the company. They advised the company not merely that it was expedient, but that it was necessary that the notice should be altered, and they gave what was equivalent to an undertaking that no further lists should be sent out. Unfortunately, the company have not only not kept that undertaking, but they have issued, subsequent to the letter, a circular containing the obnoxious paragraph, and the company have also thought fit to assert their right to do so. They issue that, after the advice of their solicitors that an alteration was necessary, and after the fact that that advice which had been tendered to the company had been made known to the persons whose interests were affected by it. To have issued that, with knowledge of the necessity of an alteration, was not, in my opinion, right, and I do not believe that the Company ever intended to do it. If it had not been for the justification that there may have been a slip, there would have been really no case. However, they choose to assert their right, notwithstanding the advice of their solicitors that an alteration was necessary. I am bound to say that I do not think the statement is one which an honest man would ever make. I do not think that an honest man would desire, without speaking subject to a condition, or referring to the decision of the Court, to say in an unqualified manner that that which a competent Court has decided to be false is true. If, notwithstanding my decision, they had stated their opinion as to the superiority of the decision of Lord McLaren to that of mine, or if they had in any way indicated that a Court of competent jurisdiction had decided contrary to what I had decided, no objection could be taken. I repeat the unqualified setting forth of a proposition which a competent Court has determined to be false, and which affects the interest of a third person, is not, in my judgment, a statement which an honest man would make, still less could it be made honestly after they had been advised by competent solicitors that the statement must be altered. I come, therefore, to the conclusion that the company are not honestly asserting their right when they assert a right to retain this paragraph. The next question is this, have the plaintiffs shown that their pecuniary interest and their rights are likely in all probability to be affected by the statement so set out by the defendants? It appears that the plaintiff company are the assigns of the other plaintiffs, Messrs. Ormes and Eldred. It appeared that Messrs. Ormes and Eldred have ever since June, 1881, been the assigns of Mr. Hunnings's patent. It appears that, in consequence of similar statements, their royalties have been brought down to zero, and I cannot for a moment doubt that what has had an effect in the time past will have the same effect in the time to come, and that if those statements are allowed to go forth, the interest of the plaintiffs in the patent will be injuriously affected. It appears that whereas before the statements were made a large trade was done by the licensees of Messrs. Ormes and Eldred, that business has greatly dwindled away. I think, therefore, the plaintiffs have shown that they have a pecuniary interest which is liable to be affected and injured by the statements made in the notice.

The result will be that I must grant an injunction, the terms of which will require a little consideration. It appears to me that I must restrain the defendants from setting out the paragraph which I have read, and from making any other statement that Hunnings's transmitter can not be manufactured, sold, supplied, or used in this country except under the license of the defendant company without reference to my decision; that is to say, I do not restrain them from saying that, provided they inform the public at the same time that I have decided the contrary. They are not to make the statement unless they qualify it by a reference to my decision, so long as that decision remains unreversed. There will be an injunction until the trial or further order.

PHYSICAL SOCIETY.—June 24.

Professor Clifton, President, in the Chair.

New members: Professor Bartholemew Price, Principal Viriamu Jones.

Professor G. Carey Foster moved a vote of thanks to Professor Clifton for the excellent reception accorded to the Physical Society at Oxford on the preceding Saturday, and drew attention to the high efficiency of the Clarendon Laboratory, and the admirable provision made for the teaching of physics at Oxford.

Professor W. G. Adams seconded the motion, and endorsed Professor Foster's views of the position of physical science on the Isis.

Professor Clifton, in response to the vote, stated that the University of Oxford had liberally supported him in organising the Clarendon Laboratory, giving him all the funds he required, and showing a laudable desire to put physical teaching on the best possible footing in Oxford.

Professor C. A. Bjerknes, of Christiania, was then introduced to the meeting, and assisted by his son, delivered a lecture on "Hydro-Dynamic Analogies to the Phenomena of Electricity and Magnetism," which was illustrated by experiments and projections on the screen. Professor Bjerknes has been engaged in tracing these analogies for the last twenty-five years—at first mathematically, but latterly by experiments in verification of the deductions from his formula. These experiments were shown in the Paris Electrical Exhibition last year, and have been publised repeatedly in this country. Dr. Bjerknes has, however, advanced beyond the results there shown. These were chiefly confined to illustrating the static attractions and repulsions of electricity and magnetism, but he has now taken up the subject of electro-dynamic attractions and repulsions. The former effects are shown by brass balls oscillating, or by small tambours pulsating, near each other in water. These motions are communicated to the balls and drums by pulses of air transmitted from an ingenious air pump or bellows along india rubber tubes. A pulsating drum corresponds to a magnetic pole, an oscillating body to a magnet. When two tambours are vibrating near each other in like phase they attract; when in unlike phase they repel each other. The same holds true of the oscillating balls. The stream lines round these bodies correspond to the lines of force round magnets. All the phenomena of magnetic forces were illustrated in this way by Professor Bjerknes, including diamagnetism. The more novel part of the experiments consisted in representing the attraction between two electric currents flowing in the same direction by means of two cylinders about 5in. long and 1in. in diameter, oscillating round their longitudinal axes at close quarters in the water. The cylinders were oscillated by means of a pulsating tambour which communicated its motion to them by a tooth gearing on their ends. Attraction resulted when the oscillations of the cylinders were opposed to each other, and repulsion when they were in the same direction. This is an inversion of what might have been expected to take place after the theory of Ampère. A square of four oscillating cylinders was also formed, and a fifth cylinder oscillated inside it, the attraction or repulsion exerted on the latter being observed. A hydrodynamic galvanometer was made by placing an oscillating ball (which corresponds to a magnet) beside an oscillating cylinder, the result being a deflection of the ball, according to the direction of the oscillation of the cylinder. The experiments were witnessed by a full meeting, which accorded a hearty vote of thanks to Dr. Bjerknes.

A paper by Dr. C. R. Alder Wright, F.R.S., was taken as read. It was on "The Determination of Chemical Affinity in terms of Electromotive Force" (Part 6), and on the relations between the E.M.F. in cells constructed like Daniell's cell but containing different metals, and the chemical affinities involved in their actions. The cells employed were constructed of cadmium and copper and their sulphates, zinc and cadmium and their sulphates, zinc and silver and their sulphates, cadmium and silver and their sulphates, copper and silver and their sulphates. In all cases the sulphate solutions were of equal molecular strength. The general result is that the effect of a given alteration in the character of the plates opposed to cadmium or silver was found to be practically identical with that of the same alteration in the case of a Daniell cell. Volta's law of the summation of E.M. forces sensibly holds true in the cases examined. These cells also behave like a Daniell under variations of current density. see p. 244

The Society meets again in November.

New Cable.—The Eastern Telegraph Company have obtained a firman from the Sultan of Turkey authorising it to lay down a submarine cable between Malta and Tripoli.

ELECTRIC LIGHT AND POWER GENERATOR COMPANY (LIMITED).

The ordinary general meeting of the members of this Company was held on the 27th June at the City Terminus Hotel, under the presidency of Admiral Sir Edward Augustus Inglefield, C.B., F.R.S.

The Secretary (Mr. F. H. Landon) having read the notice convening the meeting, the report of the directors was taken as read.

The Chairman: Gentlemen, before asking you to adopt that report it is my duty to give you a short history of the Company—in fact, to account to you for what we have done since the time of the formation of the Company as far back as April, 1881. Now, companies I need not inform you are usually established with the view of working some patents or some special industry. There may be bad unremunerative patents and good management, but, on the other hand, there may be valuable patents and bad managers. In both such cases the work might be unremunerative. It may also be possible to have good patents and good management, and at the same time, from various causes, the working may be unremunerative. That is the position I wish to place before you to-day, so far as the past is concerned, and to point out the excellence of our patents, that our business is an exceedingly good one, and that we have done our utmost to make it remunerative. To make the case clear I will briefly epitomise our action since the commencement of our work, when we were formed to work the Lontin patent, and took over the concession given to us by the City authorities for lighting a portion of the City. We took this over and undertook, as speedily as possible, to enter upon it, though it was to have been started on the 1st of the following May. We commenced literally without having a staff, works, workshops, tools, cables, or any of the appliances that were necessary. We experienced the greatest difficulty in finding a site for our workshops. One or two places were offered, but we found them unsuitable. At last we found a position on the other side of Southwark Bridge, and supplied ourselves with tools, cables, and everything that was necessary. We had all sorts of drawbacks afterwards. We found on the first night that we were to begin the lighting that one of our cables had been seriously damaged by an accident of the workmen or from some other cause, and we had to replace that cable. We then found that there was a difficulty the next night owing to the want of water. The water had been cut off, and it was impossible to get water to start our engines. We then sank a well and started again, but we found that the neighbours objected to the working of the engine on account of the position of the shafting. All these were drawbacks to our proceeding in earnest with the lighting of the City. Time went on, the nights were getting longer, and it was very necessary that we should make a start before the nights got too long for working properly. At this point of our progress we had offered to us an incandescent lamp, the Company at the time of its formation having none. That lamp is well known as the Maxim. Now that lamp was exhibited in various places in London, and the result not only of our own evidence, but of all the evidence we could obtain, was that we bought it. Our electrician, Mr. Crookes, advised us on no account to lose the chance of obtaining that particular lamp. The price asked was very large—£100,000. Nevertheless, we felt that if it were possible to obtain it we must make a stretch and do so. After some little negotiation between the seller and ourselves we succeeded in bringing the price down to £54,500, of which £22,500 was to be in shares, and £32,000 in cash. We completed this agreement, and found ourselves then possessed not only of a very excellent incandescent lamp, but part of the terms of purchase was that we should also buy the Weston arc lamp. It was necessary that we should take this over with a number of patents connected with other purchases, and that we might lose no time we immediately made arrangements for having lamps and apparatus sent over to us from America. The trial we made between the Lontin and the Weston light decided the directors that the Weston was the more suitable for putting up in the City. We therefore had a number of them imported and put in position. The nights had now become so long that it was necessary to renew the carbons, which were supposed to burn for eight hours, so as to complete the whole period of darkness. It was, however, found very dangerous to the workmen while the current was passing from the lamp to shift the carbons. It was so dangerous to do so that the directors decided to stop the City lighting until we could obtain a double arc lamp such as is now burning in Queen Victoria-street. These double lamps took us some time to get from abroad. We thought, however, that we could make them, and we have done so, as well as having imported a sufficient number not only to light the City portion we contracted for, but to continue it very successfully. It was by this particular process that the Lontin was superseded by the Weston light. I mentioned to you that we had a difficulty with the cables, and we have a defective cable now. I may say here that our City lighting is not only satisfactory, but is now being worked at a certain advantage in a pecuniary point of view—nothing very large, but still it is being worked remuneratively. Now, your directors have not lost sight of the advantage which has accrued to other companies by selling concessions. We have been continually trying to do what others have done, and so successfully—to sell our patents, to have them worked in various places in the United Kingdom. We have not at present to report to you any great accession of wealth to our coffers by such sales, but at this moment we have three or four in progress, and I think I may say that something like £60,000 may be netted to the Company in a short time with reference to these concessions. We have met with great difficulty in dealing with contracts—there has been so much competition. There are now 54 electric lighting companies advertised, and though we were sixth on the list, yet still there has been so much competition that we have had great difficulty in being able to obtain remunerative work. I may give you an instance of the thing that occurs. A certain place of, I may say, public resort in London, not far from here, was proposed to be lighted by the electric light. Our manager was put in communication with the manager of that company, and the first inquiry was how much would be given as a bonus to the people connected with that institution if they gave us the light? That is not a single case. There are many cases in which we have been told that we must give something in the same way as a bonus. They appear to say—"It is not a question whether the light is good or bad. We want something for ourselves if we

Digitized by Google

give you this job." We have, therefore, from that cause found great difficulty in obtaining orders. I have a list here of no fewer than 152 estimates we have sent out to various companies, firms, and institutions. Some may come in yet, but we know that a great many of those who made applications to us carried away from our office the price we estimated for and took it to some other company, which for a smaller sum got the work. We have made it a rule not to do more than a certain amount of advertising. We have done a certain amount of *bonâ fide* paying work. I will read it. First there is the City lighting, all of which is done from our works on the other side of Southwark Bridge. We have also three stations on the Metropolitan Railway lighted with the Weston lamp. Her Majesty's ships the "Agamemnon" and the "Polyphemus" are supplied by us with the incandescent lamp. The Edinburgh Post Office has been lighted by us very successfully for a considerable time. The *Western Mail* offices are lighted with our light. Maples, the great furnishers, have had some of our arc lights for eight or nine months. At Liverpool, the Prince of Wales's Theatre is lighted; in addition to which I may state that we have supplied our light to Messrs. Cash, of Coventry; Messrs. Brown, of Wigan; Messrs. Duff and Rowntree, Durham; the Risca Colliery, the Glasgow Fine Art Gallery, the Norwich Free Library, Messrs. T. and E. Hall, Dartford. At Windsor Castle our light was selected from others for lighting the courtyard, in connection with the Royal marriage. A few nights ago, too, our light was specially selected by a Royal personage, who would have no other, for the particular occasion of a *fête* at the Botanical Gardens. I was present, and the light was very much admired. I should like to mention one fact, which later on you must deal with. The Maxim lamp might belong to us or any other company. We are called the Electric Light and Power Generator Company, and that title is now so common that it has become difficult to connect our Company with the lights we possess, and therefore we propose to make a change in the name of the Company to overcome that difficulty. Although we cannot show any long list of places where our light is used, we have had numerous proposals as to future operations. We have concluded a contract for lighting Pentonville. One of the difficulties in connection with the contract was getting a piece of ground to put our engine on. Through Colonel Penton we have now got that facility. We propose to light Pentonville with the incandescent light in the ordinary street lamps. That will be very much cheaper than having to put up new lamps, such as those we have erected in the City. There is another place we are tendering for, but as to that the metropolitan authorities have not yet decided. The question of forming branch companies has been thought of by the directors, and they have not been idle in trying to get promoters of companies to take concessions of our patents. We have certain transactions now which may benefit us in the round sum of about £60,000. We are in treaty for concessions for two large districts—one abroad, that is Australia, and the other in the northern part of England. Perhaps it would be right for me now to allude to a question, which is very often put to me—How comes it that an officer of your Company—that your consulting electrician, who is an officer of the Company and a salaried officer—has lately become a director on the board of a new company, and has, we understand, sold an invention of his to that company when we know that all his inventions were offered first to your Company. I think this is a very proper time for me to explain to you that as far back as when the Maxim patent was offered to us Mr. Crookes informed us that he had a lamp which he would shortly perfect, and of which this Company should have the refusal. It might be asked, why did you want it when you had the Maxim lamp? The answer is, we had an economical working in the Maxim lamp—to fifty lights. We know that with the Swan and some other incandescent lamps their great advantage is that they can subdivide their lights in connection with other lamps varying from 10 to 15 and to 20 candle-power. It was very important that we should obtain, if possible, an incandescent light of comparatively small candle-power. We, therefore, entertained Mr. Crookes's proposal. I and several of the directors went to his house and saw the experiments, and were very favourably disposed towards accepting his lamp and purchasing the patent. When the time came for us to acquire it the question arose how far this lamp, which burnt well, had durability—that is, the length of time it could remain burning without being destroyed. It was necessary that we should have a certain number to experiment on. Mr. Crookes's laboratory did not admit of our making these experiments, and in the meantime we thought it right to protect ourselves and the shareholders before purchasing another incandescent light to refer to certain professional experts (of opinion foreign to ourselves) as to whether the light Mr. Crookes brought forward was one we should purchase and that would be beneficial to the Company. Two professional gentlemen who are well known in the scientific world, and another gentleman whose name is associated with the electric light formed a committee, and, after receiving their report, we decided it would only be prudent for us to defer purchasing that lamp till we could have a positive report from our manager as to its durability. Now, as these lamps could not be produced in sufficient numbers to test them for a sufficient length of time, the transaction fell through, and, as Mr. Crookes informed us that his lamp was one that was sought for in the market, and that he had had better offers than that which we made, we were obliged to request that if he were in treaty with other companies he would not attend at our board meetings except on special occasions. Shortly after we not only heard that Mr. Crookes's lamp was to be sold to another company, but he disposed of his interest in this Company, and that affected us prejudicially. I think this explanation is necessary, because some damage has been done to the Company. Meantime, however, we have been made independent of any smaller candle-power by having the means of making ten and twenty candle Maxim incandescent lights. We have seen lately an advertisement in the papers to the effect that Mr. Crookes's lamp had been bought for a large sum, and as Mr. Crookes has become a director of that company we have been daily expecting to receive his resignation, as we feel that it is impossible for him to serve two masters—one company with one incandescent lamp, and another company with a different incandescent lamp.

A Shareholder: Does Mr. Crookes receive a salary?

The Chairman: He receives a salary of £600 a year.

The Shareholder: Cannot he be called on to resign?

The Chairman: We leave that to his good taste. He is engaged to us for two years. Only one year of that period has elapsed, but at the end of the other year we could at once dispense with his services. As to what we have done with our Maxim lamp, it has been frequently used at banquets at the Crystal Palace and in various other places. It has such a good name in the market that the Jablochkoff Company applied for a concession for its use, and we made these favourable terms—that while they would employ no other incandescent lamp but ours they would let us sell concessions to other companies. Therefore, they are bound to the Maxim incandescent lamp and none other, while we can dispose of our concessions in places where the Jablochkoff Company may be working. We have also sold the Maxim lamp to another company on very favourable terms—the Railway and Electric Lighting Company. We have at present before us several proposals for street and shop lighting in various cities; but I think it is no news to you to hear that every one is waiting to see if something better will turn up. We hear of other companies working very successfully, but if most of those who are actually working were analysed it would be found in a great many cases that they were purely advertisement works—works which, if we had a large capital at our command, we might have done ourselves. I may, I think, now tell you what we have done in the way of advertising. We felt it was necessary that our lamps should be seen, not only by men engaged in the City, but by people requiring it in their country places, and places at the west end. We have been in great measure tied for want of a larger capital at our back, and for that reason our exhibition at the Crystal Palace was not so grand as those of other companies. We only had one engine there, while other companies had eight or ten. We think, however, that we are now beginning to reap the fruits of our working. We have exhibited our light at various places (which he mentioned). There are several other places where our lamps have been lent for exhibition. I have not enumerated them here, but still they have been seen, and I think we are now deriving some benefit from the time that has been spent, and which some of you, I know, believe has been spent without much benefit to you as shareholders. I have now given you a slight history of our past, and I think I should now shadow forth something of our plans for the future. We have now good manufacturing premises on the other side of the river. Those premises were originally put up for the purpose of the arc lamp. We have never tried to make dynamo machines, we find we can buy those as cheaply, but we have very good manufacturing premises for the arc lamp. We have also established a manufactory for making the incandescent lamp. We have now over 10,000 in store, and a number of arc lamps in construction. I may also say that Mr. Maxim has been over to this country. He is a man full of intelligence, and, perhaps, as clever an engineer as can be found in the world, and he has offered his services to the Company. At the present moment we did not feel justified in accepting them, for he is a gentleman who requires a very large salary. The company he is connected with in America has allowed him to offer his services to this Company. He is now in France, and requires to return to America, but he has placed himself at our disposal, and we have the refusal of his services for six months to come. We are therefore not obliged to engage his services at present, but in the meantime we have all the benefit of his advice. We propose, if the opportunity occurs, to establish small local companies with or without concessions. But we think, if we can get small companies who will take up our systems of lighting and pay us a royalty for the use of our patents, that will be very profitable. When I say that we have 1,200 shareholders on our list I think some of you might assist us in letting it be known among your friends that we possess the best arc lamp, and certainly the best incandescent lamp in the market. If you help us in that way you will strengthen our hands and assist your own pockets. We are, as I have told you, in negotiation for selling a concession in Australia for a very large amount, and also a concession for the north of England. We are also negotiating in connection with some very valuable contracts which will be very paying, and yield large profits to the Company, which is what we are looking forward to very anxiously. I think I have now put before you generally our history in the past, and what we hope from the future. I shall, therefore, conclude by asking you to adopt the accounts and balance-sheet already issued to you.

Sir Herbert Bruce Sandford: I beg to second the adoption of the accounts and balance-sheet as already issued to the shareholders. Our chairman's very exhaustive speech has covered the ground so thoroughly that there is scarcely anything in the accounts which is not mentioned in his speech. There is, however, one item as to which I think a few words may be interesting—the parliamentary expenses. That brings us to the association of the electric companies, which was formed chiefly through the general movement of this Company. The directors felt last autumn that it would be very desirable that the leading electric companies, while entering into competition as keenly as they chose with each other, should unite with each other in forwarding the interests which all had in common. We were joined very favourably in this idea by the leading companies. We met together, and do so once a month, and one of our first arrangements was to get by every possible means parliamentary powers to take up streets in various cities and towns where corporations or individuals wished us to do so. We found that very few corporations had the power to grant us those powers. At Glasgow, for instance, the gas company had such power that the corporation could not allow the streets to be taken up. We pushed forward our Bill at considerable expense, though at much less expense than if we had not had our association. The Board of Trade, seeing the general desire for such powers, took up the matter, and stated that if it had not been for the course we took in that respect their hands would not have been so strong in going before Parliament. The special committee has reported on the Bill, and if other troubles in Parliament will allow of it we hope to have the Bill passed in July. That will relieve us from a very great difficulty in getting contracts given to us by those who wish their houses and public buildings illuminated by electricity.

Mr. Storey referred to the large sum paid for patents, the number of patents in existence, and the possibility of litigation. He suggested that the chairman should inform them whether their patents had been handed over to them guaranteed free from litigation. If so what security had been taken to ensure that, and, finally, he should like to know in what position the Company would find themselves in in case decisions should be given against them.

Mr. Wheeler thought it advisable that the meeting should express some opinion with reference to Mr. Crookes's position—an opinion as to the expediency of his retiring from the Company. Such an expression of opinion would probably help that gentleman to make up his mind more quickly.

Mr. Crookes: May I be allowed to say a few words, not being a share-

Digitized by Google

holder? In the first place I may say that I have listened with very great pleasure to the account the chairman has given to you of the very favourable prospects of the Company. No one has heard that with greater pleasure than I. I look on this Company as almost one of my children. It was thought of by me—or the Company embracing the principal object this Company was formed to work out—four or five years ago, and I have been in constant communication with Mr. Harding since then. I may say that the original prospectus was drawn up in my library, and the directors were selected by myself and friends before it came before the public. I have watched the Company from the very commencement, and have done all I could to forward the interests of the Company, and nothing has given me greater pleasure than in hearing the chairman say its prospects are so good, as to which I feel that the shareholders are to be congratulated. It so happens that I have been connected with electric lighting for a great many years. I have been experimenting in my laboratory, and I felt that when electric lighting was coming to the front I ought in justice to myself to put into force a great many discoveries I had made in scientific matters relating to the electric light. Before this Company was formed it was mentioned that I had an incandescent lamp. It was not perfect then, but sufficiently advanced for me to foreshadow what it would be. In the first prospectus submitted my name appeared as one of the directors, but that was left out at my own request because it was understood that the Company would have to purchase my lamps. Since then I have been consulting electrician to the Company and given them advice. At first I attended the board meetings regularly at the request of the board, or by right as one of the committee of the council of reference. However, that does not matter. Constantly, from that time till a few months ago, the subject of lamps and my patents came up. I was one of the jury at Paris examining the incandescent lamps. I saw exactly what one was worth and what another was worth. Naturally, without saying anything in favour of my own, I know what my own incandescent lamp is worth. There was, some time since, a great *furore* in connection with electric lighting companies, and patentees could get whatever they asked for their patents. In fact, it got into six figures. I, however, adhered to the offer I made to the Company, which was a very moderate one. I said, "Pay my expenses" (which had been very heavy), "give me so many shares and a small royalty or per centage on the sale of the lamps." During that time I was, I will not say bothered, but I was asked by a great many people about my lamp. I, however, kept the negotiations going on with the company until the *furore* went over. I ran the chance of losing the market for my lamp. I think the chairman has given you—with a little natural colour, which must distinguish anything that comes from that side of the table on a matter of that sort—a fair explanation. The thing went through because I declined to have my lamps put to a test which I knew they could not be put to. There was no apparatus for the purpose. The chairman says he is surprised I have not resigned my seat at the board. I suppose that was a slip, for I am not a member of the board. I am the consulting electrician of the company for two years. But I am tied to the company; I cannot get out of it. I am ready if I can. At the start it was thought that these arrangements should be made with me, and I said I had no objection to it. I should however be very glad, if it is the wish of the meeting, to give up that position [hear, hear]. I should be happy to bow to the wish of the meeting. The work I have had to do has been very little lately—some patents to report on. If there had been the slightest wish on the part of the shareholders to release me from my engagement, I should have been ready to fall in with their wishes. As far as selling my shares is concerned I was quite within my own rights in doing so. I bought them with my own money, and sold them when it was convenient to myself to do so. I simply exercised my right to sell them, but I may feel inclined after the glowing account which has been given by the chairman to go in and buy. If anything arises in the discussion I shall be happy to give any explanation.

The CHAIRMAN: I am very glad to answer the last speaker's question first. Mr. Crookes has given me credit for straightforward speaking as to the transactions between the Company and himself. The directors have had many times under consideration the question of asking Mr. Crookes whether he would resign, but we always ended by thinking that it would be better to leave it till he saw the wisdom of being released from being a salaried officer of the Company. Seeing that we could no longer have the unprejudiced services of Mr. Crookes, and that he had the heavy salary of £600 a year, you can easily understand that we should have been quite ready to receive Mr. Crookes's resignation some months ago. We, however, thought it would be more courteous not to suggest his resignation till he himself saw fit, as he has done to-day, very properly and handsomely to tender it. As to the conditions of acquiring his lamp, one was that we should establish a factory somewhere in the neighbourhood of his own house, and that £10,000 was to be put aside so that his invention might not be allowed to starve. This was a question very anxiously considered by the board, and we had meetings day after day with Mr. Crookes and his friends, but we felt, after the long report we received from the professional gentleman to whom I have referred, and to whom we pinned our faith, to act as we did. The report we had in our hands said we cannot report on the quality of the endurance of these lamps, as we have not had a sufficient number to test, and we shall not recommend you to deal with it till you have tested them for their endurance. I am not saying a word against Mr. Crookes's lamp, but if it should hereafter become the first incandescent lamp in the world, I believe you will approve of the course we took. If Mr. Crookes had brought us twenty incandescent lamps we should have put them through the test. We were very anxious on the subject, but we considered that we were trustees for you, and that having purchased at a very large price on our own responsibility one incandescent lamp, we did not feel justified in giving this large price. From first to last the cost would have been £30,000 to go out of the pockets of the Company for the benefit of having the lamp. I need say no more on the subject. As to our patents and their validity being guaranteed, that is a very important question, but one that no company has been able satisfactorily to settle. I believe we do possess some of the earliest patents, and in a trial that took place in America between the Edison and the Maxim as to which had priority of patents I may tell you that the Maxim gained the day. Therefore, I think we may consider that our Maxim lamp is not challenged. I may also say as to our dynamo machine that, while the Gramme and others are threatened, we have had no threat as to ours, though we may get it any day. Meantime we are going on very successfully with the Maxim and the Weston patents. But, as Mr. Crookes argued, we all think our own babies best. In granting concessions you may have seen that another company which have granted a great number have invariably said that they would not guarantee their patents to those to whom they sold concessions. We were obliged in purchasing the Maxim and Weston patents to accept the same terms, though they offered to pay half the law expenses that might be incurred in testing this validity.

Mr. WILLIAM ABBOTT emphatically held that the course taken by the directors was the best in the interests of the Company. They had several patents, and believed—he for his own part believed—that they had the very best incandescent lamp, and, therefore, why multiply them? Instead of patentees starving he thought that shareholders would starve if that course were adopted. At the last meeting he suggested that the directors should leave municipalities to be dealt with by those enterprising gentlemen who were very anxious to do a large amount of work for very little pay. That might suit those gentleman but not this Company. He would submit to them that the experimental stage had been passed by this Company, and that they should now devote their time to the lighting of factories, &c., and the sale of their lamps, and thus obtain profits as soon as possible. He thought that that was the principle they should adopt, and if it were adopted they need have no fear of the future of the Company.

The CHAIRMAN: That is our intention—to direct our entire attention now to domestic lighting, to obtain such contracts as will bring in actual remunerative work. I think we might have obtained a great deal more work had we been satisfied to do it at bare profits, or no profits at all. There is one point I omitted to allude to. We have had certain overtures made to us for the purchase of one of our patents—the Rapieff lamp, which was included in the patents we bought, but which we have not worked for some time. There are those who think it might be worked profitably, and we are now in treaty for a good round sum for the disposal of that patent. We are so satisfied that the Weston arc and the Maxim incandescent are the patents we can work most satisfactorily with, and with good remuneration, that we have decided, if a favourable opportunity occurred, to part with our Lontin and our Rapieff patents, but we shall not do so except under proper advice. We think it right, as the Company was formed for working the Lontin patent, to tell you that it is our intention to part with the Lontin as well as the Rapieff patents, which we are entitled by the Articles of Association to do as directors for the benefit of the shareholders. I think this is also the moment when I should say a word or two as to the Electric Light Association. It was originated by the Company because we found so much underhand working—greasing palms—going on. We, therefore, invited the co-operation of other companies to form an association to protect our rights and agree as to certain regulations with regard to each other. I think some ten or twelve regulations were drawn up, on which we are acting in concert with each other. We meet at our offices every month, and there transact a great deal of business for the benefit of electric lighting generally. It has been not only of great utility in the forming and arranging of parliamentary business, but useful in certain other matters in which all the companies are interested alike. I may instance one matter, which is the extraordinary rise that insurance companies have made upon houses that have employed the electric light. That is a matter continually under the consideration of this association's meetings, and I think we shall be able to bring it to a very satisfactory issue. To this Company is due the credit of having formed that association, and I hope you will give us credit for having done so. It has been the means of saving us a great deal of money, as we agreed that the associated companies should work with one set of solicitors, and one set of parliamentary agents, and we have agreed, when the Bill passes, to divide the expenses among those companies who are associated. We only agreed to associate ourselves with first-rate companies—not any mushroom company that might spring up at any moment, but certain companies with good names, and well known in the mercantile world.

Mr. ABBOTT suggested, as he was always jealous of the rights of shareholders, that the directors should not part with any of the Company's patents without first laying the matter before a meeting of the shareholders. Such a meeting would cost nothing, and would be more assuring to the proprietors.

The CHAIRMAN: I am afraid you are rather late with respect to the Rapieff patent, as we have entered into a very good contract for that. We have found it impossible to work the Rapieff. The negotiations may lapse in the course of two months, but other parties have the refusal of it for that time. As to the Lontin, we have as yet taken no steps.

A SHAREHOLDER thought the matter might be very well left in the hands of the directors.

The Chairman then put the motion, and it was carried unanimously; and the retiring directors, Sir E. A. Inglefield and Sir H. B. Sandford, were subsequently re-elected.

The CHAIRMAN having replied on behalf of Sir H. B. Sandford and himself,

A resolution was passed re-electing Mr. Henry Dever the auditor of the Company, at a remuneration of 30 guineas.

The meeting was then made special, and

The SECRETARY having read the notice,

The CHAIRMAN said: I have very few words to say, but our reason for the proposed change in the name of the Company is this: when we were first formed we were the sixth Company, and we took the title of the Electric Light and Power Generator Company, thereby enabling us to take any number of patents, work any kind of light and lamp, and to use electricity as a motive power. Since then fifty-four companies have been formed, twenty-three of whom have in a great measure pirated our patents, and also have called themselves Electric Light and Power Companies. One company, in fact, has called itself an Electric Light and Power Generating (not Generator) Company. We, therefore, in these circumstances think it will be better to call ourselves the Maxim-Weston Electric Company, by which, like the Brush Company, we shall be known at once for having these particular lamps, which it will be our business to introduce generally. I have been asked many times, To what company does the Maxim lamp belong? and then when I have mentioned this Company the remark has been, "Oh, the company of which so-and-so is a director," mentioning one of the other twenty-three companies." I think, therefore, you will agree that it is time that we should change our name,

Digitized by Google

Mr. John Scarlett Campbell: When we started this Company we were very general in our powers. We wanted a good light, and we felt we were not thoroughly qualified in that respect, but now our lamps will show you what an admirable light we have, and I think we cannot do better than give the names of our lamps to the title of our Company. I second the motion.

The Chairman: It is moved and seconded "That the name of the Company be changed to the 'Maxim-Weston Electric Company (Limited).'" Those in favour of that will signify the same in the usual manner. To the contrary. Carried unanimously.

Mr. William Abbott then moved a vote of thanks to the chairman and directors, and expressed a hope that the directors would do even better for the shareholders in the future.

Mr. G. P. Harding seconded the motion, and it was carried unanimously.

The Chairman acknowledged the vote, and intimated that a special meeting would be necessary to confirm the resolution for altering the name of the Company.—The proceedings then terminated.

THE FAURE ELECTRIC ACCUMULATOR COMPANY (LIMITED).

An extraordinary general meeting of the above Company was held at the Terminus Hotel, Cannon-street, on Thursday, the 29th June, "for the purpose of receiving a statement from the board of directors, and considering the future policy and business of the Company under circumstances which will be explained to the meeting, and, if deemed expedient, of passing resolutions in connection therewith." Sir A. J. Otway, Bart., M.P., presided.

The Secretary (Mr. Herbert Canning) having read the notice convening the meeting,

The Chairman said: Gentlemen, you have heard the terms of the notice which the secretary has just read. We felt it our duty to ask you to meet us to-day for the purpose of carrying out the intention indicated in that notice. I say our duty, because although by the Articles of Association of our Company this board had undoubted right and power to conclude any arrangement that it thought beneficial for the Company, still the proposals which will be made known to you are of a character so important that we thought it due to the shareholders and due to the consideration that men of business should always give to their proprietary to take their opinion before coming to any definitive opinion on the matter which will be brought to your notice. Now, gentlemen, I shall ask you in considering the proposals which will be made known to you and on which you will be asked to give an opinion, I shall urge on you the necessity of considering the circumstances under which these proposals are laid before you. I shall before making known these proposals to you relate briefly the circumstances, and you will then see the importance of the suggestion I have now made. I do not know whether there are many or any of the proprietors present to-day who were with us on the occasion of our last meeting—that of our statutory meeting. If so they will remember that I indicated the policy which this board intended to pursue with regard to the affairs of which we are the administrators. That policy met generally with the approbation of those present. It is unnecessary to repeat what took place, but I will remind you that among the observations made there was one somewhat partaking of the nature of a reproach that we had not disposed of our capital; and one gentleman went so far as to say that we had commenced our business with an insufficient capital. Well, gentlemen, I did not admit at the time the justice of the reproach, but whether it was a well-founded reproach or not, scarcely had I left the room when a somewhat remarkable circumstance took place. I found that the whole of the remainder of our capital had been secured. This was very soon followed—I might almost say simultaneously—by another circumstance not less striking, not less interesting, and hardly less surprising. You are aware that when we last met we had an antagonist, a rival maker of accumulators, a powerful company, entering on business in rivalry with ourselves, and professing to have a better article than we, with which to conjure the public. We never, I need scarcely say, doubted, and, what was more, we knew that this rival accumulator could only be brought into public notice (so far as we were concerned) by violating the rights which we possessed by our patents, and in order to protect those rights, as I told you, we had instituted legal proceedings against the company which affected us. I say, then, it was with no little surprise that we learnt that a company in the supposed possession of an accumulator that was entirely to destroy that of Faure had become suddenly so convinced of the extraordinary merits of the Faure accumulator that it had purchased the patents of the Faure accumulator for all the rest of the world. We now found ourselves in this strange position, that they who were our antagonists the day before had now become more interested in the success and establishment of the Faure Company than we ourselves. Because, whereas we only held those patents for the United Kingdom, they held them for all the rest of the world. I was not at all surprised, under such a state of things, that overtures should even be made to us—a step I should think any business man would take—to come to some understanding with a company so situated as that I have now described. I should tell you that the vendor of the Faure patents for all the world, excepting the United Kingdom, being a gentleman of great ability and considerable personal experience, had very wisely made a condition with the Storage Company, to whom he had parted with them, that they should agree to a basis of understanding with the company in which we had now so very large a stake. Well, these conditions were made to us, and although we were well aware that we had an uphill struggle if we commenced one with the master of many legions, still it would have been our duty to contend wherever we thought the rights of the company—of our shareholders—had been infringed, or where we thought their interests had not been duly consulted. At first, therefore, these conditions, as they were at first offered to us, did not seem acceptable to us, but after long, and I must say exceedingly difficult negotiations—among the most difficult I have ever had—negotiations which were carried on in the largest possible spirit, not in a higgling, huckstering spirit, but influenced by the great interests involved in this matter—above all by the vast importance of establishing peace instead of wasting our money in litigation and our time and energy in unnecessary litigation, and of establishing a union of interests, and binding them into a powerful company without that company having any opponent in the world. Influenced by that spirit we were able to obtain for our company some very valuable concessions, to which we thought ourselves fully entitled, and these concessions were wisely made to our just demands, and I am bound here to recognise the large spirit with which Sir D. Cooper and those other gentlemen of the Storage Company met us, and I must also take the opportunity of recognising the very great assistance we obtained during these negotiations from M. Philippart, the vendor of the Faure patents to the Storage Company, and a very large proprietor in the interests of that company. Well, gentlemen, the result has been that an agreement has been come to if it is sanctioned by you, but in that case only. An agreement had been come to I may say substantially between the two companies. Now I shall ask Mr. Wiseman, who is by my side, to make known to you the heads of the agreement. What I may say shortly to you is this—thus asking you again to remember that which I told you just now, the circumstances under which the negotiations were carried on and the position of the large proprietors—I think you will say—my opinion is you will say—the arrangement is one singularly favourable to the interests of the Faure Company. What I do not hesitate to say is that if an arrangement of the kind were to be made between the two companies, I can hardly conceive that any one could be concluded of a character more favourable to ourselves. Well, now, what has been done is this. We have come to an arrangement of peace I may say first of all—perpetual peace, I hope it will be, between the two companies. I may say almost an alliance offensive and defensive, and we have determined in a clear and definite way what the attributes of each Company are to be as to the manufacture and use of the Faure accumulators. That which we have succeeded in preserving to ourselves is in my opinion—so far as I can form an opinion now—the most valuable of the accumulator business. We have preserved everything for instance connected with railways, either as to propelling purposes or as to lighting their stations, their carriages, their tunnels, their cafés, their restaurants—everything in short connected with railways. We have preserved for ourselves everything connected with ships—their lighting, their propulsion if necessary, whether on the sea, canals, or rivers, in short wherever ships are sailing under the British flag. We have preserved for ourselves the motive power of electricity applied to tramways and vehicles of all descriptions, bicycles, tricycles, and, gentlemen, last but by no means least, we have secured to ourselves the use of the accumulators for machinery of all kinds. You will understand that I mean we have secured the exclusive use of the accumulators for those purposes. Well, that being so, the Storage Company have acquired from us the use of the Faure accumulators in the United Kingdom of Great Britain (they possessed it for all the rest of the world already) for the lighting of houses and towns. In case there should be any omission in details which I am making known to you, Mr. Wiseman, I am sure, will correct me, as he has a *précis* here. I am speaking from the knowledge I have carried in my head for a long time. Well, there are other conditions, and one is a very important one, namely, to establish a community of interest between the two companies we have mutually had an interchange of the rates with value upon shares. When it is considered that we share in these patents, which we think so valuable, for the entire world, and that we gave the United Kingdom only to the Storage Company, I think it will be found that the proportion of the shares interchanged is also very favourable to ourselves. There are some subsidiary arrangements that are entirely favourable to ourselves. They must be favourable to ourselves as they are entirely of an optional character, and anything that is optional cannot be considered unfavourable, but we consider them very valuable. We have a right in sharing, up to a certain time, in the proportion of profits to be derived by the Storage Company in the formation of sub-companies, and the Storage Company will also give us a proportion of all the profits they have made since they began up to the present time—a proportion according to the number of our shares—and, as you are aware, that is not slight. I have now given you the heads of the agreement. I never like to detain shareholders long. I always find it the best plan to make a statement, and to ask any gentleman to whom I have not made myself sufficiently clear, to question me, so that I may explain anything he wishes to know, as far as I am able, and I think that is the best way to conduct the business of a public meeting. I shall, therefore, now conclude the statement, asking you merely to remember my opening observations, because these are all important when you come to consider your decision. This, gentlemen, I feel bound to say, and I would not consent for any consideration whatever to throw before the shareholders, as chairman of a company, a set of conditions, or proposals, without giving my own opinion upon them. I think it is the least that everybody of shareholders has a right to expect from their chairman. I say, therefore, that under the circumstances of the case, I am surprised rather that we should have been able to obtain conditions so favourable as these are. Of course a great deal will depend on working them out. Who may work them out is a question still perhaps to be determined, but I have no hesitation in telling you that still we should consider it a duty to carry out the argreement unless there was a very strong opinion on the part of the shareholders that it was an agreement disadvantageous to themselves. If the shareholders were to express a strong opinion of that kind then I think as practical men that we should be bound to consider such an expression of opinion with respect to such a matter. But I can hardly expect you will express any such opinion. You have heard my explanations, and I shall now ask any of you to make inquiries from me on any point on which you require information, and then I hope that someone in the room will be so good as to move some resolution giving an expression on the part of the body of the shareholders to the general scheme laid before you. I should mention merely that at the present moment the agreement is not signed, because it is not definitive till you have given an opinion on it. It is actually not yet drawn out in a proper manner. I have made it known to you correctly, generally speaking, and if I have omitted to state anything that should be made known Mr. Wiseman will now be so good as to mention it.

Mr. Wiseman (from the office of Messrs. Freshfields and Williams) then read a *précis* of the agreement, recapitulating in a more detailed form and slightly amplifying the information given by the chairman.

In reply to questions the Chairman said: We share for our proportion

Digitized by Google

of the Storage Company's capital in the profits of the Faure Company "all over the world" for the whole duration of the patents, and great and powerful as Great Britain is, I don't think these isles can compare in extent with the rest of the world. The gentlemen of the other company were of opinion that they had given much too much value under these circumstances. I have had a good deal of correspondence on this subject, and many shareholders are under the erroneous impression that we have been negotiating as regards the Sellon-Volckmar patents. Not at all. It is the Faure patent that we have been trying to obtain in parts of the world where we cannot use it, although the Sellon-Volckmar is not altogether without value, as I have said. We have exclusive rights as to British vessels, and as they are more numerous than all the other vessels in the world put together we have the most value there.

Mr. E. GREEN: The arrangement you have foreshadowed seems a very satisfactory one, and an advantageous one for our Company. I beg to propose that "The arrangement foreshadowed by the chairman be adopted." I think that the jump that has taken place in our shares already while this arrangement has been in course of progress has shown that it is an undoubted advantage to us.

The motion was duly seconded.

The CHAIRMAN submitted the resolution, and said: I may say that I have not in putting my remarks before you alluded to the point mentioned by a recent speaker, that is, the impression made on the public, at any rate as shown by the increased value of the shares. I always abstain from referring to these matters, and dealing with them on their own merits; but one cannot be indifferent to the value put upon such an arrangement on the part of the public. I have read the resolution. If any one has any observations to make now is the time—if not, I shall put it. The chairman then put the resolution in the usual manner, and declared it carried unanimously.

A vote of thanks to the chairman and directors was then carried unanimously, and in reply

The CHAIRMAN said: I am very much obliged to you. It is our duty to do what we can to carry this affair to a great success. It is one of the most interesting inventions of modern times, and one which I have not the slightest doubt has a very great future before it.

The meeting then separated.

THE METROPOLITAN (BRUSH) ELECTRIC LIGHT and POWER COMPANY (Limited).

Managing Director—ROBERT HAMMOND, Esq.

This Company is now prepared to undertake CONTRACTS for LIGHTING STREETS, Public Buildings, Churches, Theatres, &c., with the Brush Arc Light and the Lane-Fox Incandescent Lamps throughout the whole of the Metropolitan Postal District. Also to supply complete Installations of their system to those who wish to have the Electric Light immediately, instead of waiting for the formation of electric lighting stations, which will shortly be opened, in addition to those at Holborn and Westminster already in operation.

The services of a thoroughly efficient staff will be immediately brought to bear upon any work entrusted to the Company, and they will be happy to arrange for a practical engineer to inspect any premises in order that the exact estimate of the cost of lighting may be given.

The Brush Light has already been erected at Messrs. Peek, Frean, and Co.'s; the Clock Tower, Westminster; Alexandra Palace, the Admiralty, Woolwich Arsenal, South Kensington Museum, the Inns of Court Hotel, the Royal Music Hall, the Combination Stores, and the stations of the South Eastern Railway Company, Great Western Railway, South Western Railway, &c.

All particulars, prices, and estimates may be had from the office of the Company, 110, Cannon-street, E.C.

ROBERT WILSON, Secretary.

WANTED, to place a Youth as PUPIL with a firm of Electrical Engineers, where he will receive thorough practical and theoretical instruction in the modern applications of electricity. Apply to Mr. THOMAS COOTE, North-terrace, Bishops Stortford, Herts.

THE EXCHANGE TELEGRAPH COMPANY, LIMITED.

Head Offices—17 & 18, Cornhill, E.C.; Stock Exchange, E.C.; 27, Regent Street, W.

Incorporated the 28th March, 1872, under the Companies Acts of 1862 and 1867, and by Special License from H.M. Postmaster-General.

This Company will undertake to supply recording instruments, telegraphically connected with the Stock Exchange, by the aid of which Subscribers, at their respective offices, may be kept continuously advised throughout the day of the constantly occurring market fluctuations in stocks and shares.

Instruments are placed in the offices of Subscribers and kept in order by the Company, free of every expense but that of rent, and inspectors visit them daily to supply ink and paper.

Terms: £50 per annum, payable quarterly in advance.

Applications for instruments to be made to the Secretary at the above address.

Not having any springs or clockwork to wind up or to depend on, these instruments are acknowledged by those familiar with the system of telegraphy to be the only instruments yet invented that are capable of doing the work required of them continuously for a lengthened period, as evidenced by the fact that the Gold and Stock Company of New York, having the monopoly of this kind of business in the States, and which owns all the patents of the day of any value, has, after due trial, discarded all others.

The Company is prepared to treat with provincial Companies requiring instruments for the delivery of news for either single or double wire systems under the Company's patents, whereby from central stations identical information can be simultaneously delivered to any number of recipients by automatic, self-adjusting, printing instruments requiring no local batteries, no winding up, and no knowledge of telegraphy on the part of the receiver, the printing being in bold roman type, and the propulsion of the paper being effected by the electricity supplied from the Central Office.

The instruments supplied by the Company can be had to work either on single or double wires, and to print either on a slip or tape of paper, as has hitherto been the custom, or on a broad band of paper in column form.

The system has been in use by the Exchange Telegraph Company (Limited) in the City and West End of London since 1872, and by MacMahon's Telegraphic News Company (Limited), for the delivery of Parliamentary, Sporting, and General Intelligence, since 1879.

The Company will supply householders and others with its

DISTRICT CALL SYSTEM.

By the aid of a small automatic telegraph instrument a Subscriber can at any hour, day or night, call a messenger, cab, or policeman, or give the alarm of fire, and will obtain the required assistance within three minutes of making the signal. Subscribers, when absent from their homes for a season, can leave their houses closed, and have them taken charge of by the Company, and rendered perfectly secure against burglars by a telegraphic communication with the nearest District Call Station of the Company, where a policeman will always be in readiness day and night to respond to calls.

Provincial combinations to work under the Company's Patents will be treated liberally.

The Company is also prepared to supply Municipalities with its system of

STREET FIRE ALARMS

as recommended by H. M. Postal Telegraph Department to the Metropolitan Board of Works for the Metropolitan Fire Brigade, and which has received favourable mention by Captain Shaw in his last annual report.

These Alarms have recently been considerably improved by the Company, and are acknowledged to be the simplest yet constructed.

All communications to be addressed to the Secretary as above.

Digitized by Google

RECENT INVENTIONS.

ABSTRACTS OF SPECIFICATIONS.

2538. ELECTRIC AND MAGNETIC BRAKES, &c., *M. R. Ward, London.—10th June*, 1881. 6*d*.

The inventor does away with brake blocks, and employs a dynamo-electric machine for each carriage, the machine being connected with and put in motion by an endless band or other gearing from the axles of the carriage. These machines are so arranged that when the circuit in which they are included is closed, the action of the electric energy produced will retard the motion of the train. When the circuit is not closed the dynamo machine will revolve freely, and give out a current which may be utilised to produce heat, light, or to charge secondary batteries, which in turn shall feed excentric lamps.

2739. IMPROVEMENTS IN THE MODE OF AND APPARATUS FOR DISTRIBUTING ELECTRICITY, APPLICABLE TO THE PRODUCTION OF THE ELECTRIC LIGHT, &c., *H. E. Newton, London.—22nd June*, 1881.—(*A communication from A. Gravier, Paris.*) 8*d*.

This invention consists in the application of derived circuits so as to distribute the electric currents to any number of apparatus, which shall all be independent of one another, and shall only absorb the exact amount of current required to work each one.

2954. IMPROVEMENTS IN MAGNETO OR DYNAMO-ELECTRIC MACHINES OR ELECTRIC ENGINES, *P. Jenson, London.—(A communication from T. A. Edison, Menlo Park, N.J.)—6th July*, 1881. 6*d*.

The object of this invention is to do away with the iron core of the armature, and the loss of power through the heating thereof, also to generate continuous currents of high electromotive force in the same direction without using pole chargers. This is accomplished by constructing the armature in the shape of a disc, but divided into radial sections. These sections are naked copper bars joined edgwise by a non-conducting material, so that they form a rigid disc, and rigidly attached to the driving shaft by means of an insulating hub.

2981. MIDDLINGS PURIFIERS, *E. G. Brewer, London.—7th July*, 1881.—(*A communication from K. Smith, Minnesota, U.S.*) 6*d*.

An electrified surface is used to attract the particles of bran, which are removed from its surface, the flour not being attracted, and the inertia of the material as it falls is made use of to separate the middlings and bran to a certain extent, allowing the bran to fall near to the electrified surface and the middlings to be more remote. The middlings pass from a hopper and fall through the air on to an incline or cant board that partially arrests the velocity, and the material rebounds against the cant boards, and then slides off and falls, the meal or flour falling further off than the bran. An electrified surface such as a roller or band of vulcanite acted upon by rubbers is placed as close to the line in which the bran falls as is convenient, and the particles of bran are attracted and removed by scrapers.

2995. IMPROVEMENTS IN TELEPHONIC AND TELEGRAPHIC SIGNALLING APPARATUS, *A. C. Brown and H. A. C. Saunders, London.—7th July*, 1881. 6*d*.

The object of this invention is to facilitate intercommunication between several telephone stations on one wire. The apparatus is so arranged that not only can any station call up and place itself in direct communication with any other station on the same wire without having to go through a central office, but also so that none of the other stations can interrupt or hear what is passing. The instruments and mode of arrangement were illustrated and described in our articles on the Crystal Palace Exhibition.

3009. MONEY TILLS, *B. W. Webb, London,—8th July*, 1881. 8*d*.

The object is to prevent fraud, and consists of a series of toothed wheels and indexes operating to indicate on dials any sum paid, and to simultaneously cause the ringing of electric bells, which tell the amount registered by striking as many times as there are pounds, shillings, or pence in the amount received.

3032. IMPROVEMENTS IN REGULATING ELECTRIC CURRENTS AND IN THE APPRATUS OR MEANS EMPLOYED THEREIN, *Sir W. Thomson, Glasgow.—9th July*, 1881. 10*d*.

This invention consists in an automatic appliance for regulating by means of electro-magnetic force the work of an electric accumulator or voltaic battery by increasing or diminishing the number of working cells. One species of this appliance gives a constant strength of current, another a constant electromotive force.

3073. IMPROVEMENTS IN LAMP CASINGS OR HOLDERS FOR CONTAINING AND PROTECTING ELECTRIC LIGHTS, &c., *D. Graham, jun, Glasgow.—14th July*, 1881.—(*Not proceeded with.*) 2*d*.

This relates to an improved kind of lanthorn for holding incandescent and arc lamps, and to a means for fixing the lamps in the lanthorn. Also to an improved contact piece in which water and mercury are contained, the water being designed to prevent the spark occasioned by contact being made from setting fire to any gases, &c., that may be near

3122. IMPROVEMENTS IN THE MANUFACTURE OF ELECTRIC BRIDGES FOR LAMPS, *St. George Lane-Fox, Westminter.—18th July*, 1881. 2*d*.

The inventor uses the Italian grass (Andropogon Ischœmum), known as French whisk, for his electric bridges, or carbons, for incandescent lamps. He boils the grass in a solution of caustic soda (5 per cent.) The outer skin is then scraped off, and the fibre boiled in water. It is then straightened, bound on a block of carbon, burned in a crucible, and carbonised.

3228. IMPROVEMENTS IN APPRATUS FOR CONTROLLING TELEPHONIC COMMICATIONS, *J. Imray, London.—23rd July*, 1881.—(*A communication from L. A. Brasseur and O. Dejaer, Brussels.*) 8*d*.

The improvements consist in the use of a distributing tablet, as it is called by the inventors, which has a number of keyholes, one for each subscriber. When a subscriber A wants to communicate with another B, a key is placed in A's hole in the tablet, and when turned, disconnects the signal. The attendant at the commutator then does the same, and communicates with A, and subsequently informs the attendant at the tablet that he wishes to communicate with B, the latter puts another key into the hole belonging to B, and by turning it puts him into communication with A. The key consists of a shank on which are insulated pieces of metal, which on the key being turned one quarter round bears against lateral springs fixed on an ebonite casing of the key; these springs communicate by insulated wires with the line, return, and battery. The key cannot be withdrawn without turning it back, and this act connects A and B to central office. By means of interrupters, any attempt to listen to the conversation of A and B by connecting up to their line breaks up the connection between them, and by means of a current from the central station informs them of the interruption. Induction is avoided with instuments having two wires by combining with them one inducing and two induced coils.

3327. ELECTRIC APPARATUS FOR AUTOMATICALLY GIVING ALARMS, *J. L. Rastrick, London.—30th July*, 1881.—(*Not proceeded with.*) 2*d*.

The expansion of matter was utilised to cause an electric contact, and hence to give an alarm.

3404. IMPROVEMENTS IN APPARATUS OR APPLIANCES FOR AUTOMATICALLY LIGHTING ELECTRIC CANDLES, *E. G. Brewer, London.—5th August*, 1881.—(*A communication from A. G. Desquiens, Paris.—(Not proceeded with.)* 2*d*.

The invention consists of two supports for each candle, having levers and arms acted on by springs which put the two supports in electric connection when the candle is consumed. The springs are released by the action of heat on a brass pin placed at the bottom of the candle.

3509. IMPROVEMENTS IN ELECTRICAL INTERRUPTERS, *P. Ullathorne, London.—12th August*, 1881. 6*d*.

The instrument consists of three stretched wires nearly parallel but not in the same plane. The contact or anvil wire is platinised at its contact point, and is insulated from the other two which are attached to the ends of a soft iron armature, lying in a plane between the contact wire and the other two external wires; the part of the armature making contact is also platinised. The wires are stretched over bridges, so that the armature bisects the vibrating portion of the wires to which it is attached, and these are equally stretched and equal in other respects. The contact wire is also stretched on bridges, one of which is near the armature. An electro-magnet is placed on that side of the armature furthest from the contact wire. Supposing the current to enter the electro-magnet, it passes to the ends of the armature wire and into the armature; from here it goes to the contact wire, and exits from one or both ends of the vibrating part of the contact wire. Modifications of this mode of construction are also described and the instruments illustrated.

3559. IMPROVEMENTS IN ELECTRIC LIGHTING AND IN THE MEANS OR APPARATUS EMPLOYED THEREIN, *C. W. Harrison, London.—16th August*, 1881. 6*d*.

The inventor makes use of a reflector of solid roestone in slabs, or uses it as a base, and mixes therewith gypsum and oolite, bringing the whole into a fluid state by a solution of potash; the mixture is then dried in blocks at a low heat, and subsequently hydraulicly pressed into a hard mass. The inventor varies the colour of the light given by the arc by adding liquid sulphates of various bodies to this reflecting material, according to the tint required.

3668. IMPROVEMENTS IN ELECTRIC LIGHTING APPARATUS, *W. R. Lake, London.—23rd August*, 1881.—(*A communication from T. A. Connolly, Washington, U.S.*) 6*d*.

This consists in the employment of an automatic switch in connection with the electro-magnet, through which the upper carbon is fed, by means of which, should the arc become defective from any cause, the current will be diverted through the lamp frame, and out at the same terminal as when the arc was established, so that the other lamps in circuit would not be affected. The feeding of the carbons is accomplished by clamps attached to the armatures of electro-magnets.

3754. IMPROVEMENTS IN SHEATHING OR COATING METAL SURFACES, &c., *W. Elmore and J. J. Atkinson, London.—29th August*, 1881. 6*d*.

The inventors employ an electric motor hung upon rods around the work to be coated, and driven by this motor a hand emery wheel for cleaning the spots or metal required to be covered. They also use an electrical depositing tool consisting of a conducting rod, carrying at its end a disc of the metal to be deposited, which forms the anode. This disc is covered with a pad of felt, moistened with a solution of the above metal, it is then brought into contact with the surface to be coated. The cathode wire of the circuit is then connected with the metal to be coated and the wetting pad applied, when a deposit of the metal is effected on the cleaned surface. Thus the coating of the spots that have been cleaned is effected with great rapidity.

3804. IMPROVEMENTS IN COMMUTATORS FOR DYNAMO OR MAGNETO ELECTRIC MACHINES AND ELECTRIC MOTORS, &c., *P. Jensen, London.—1st Septmber*, 1881.—(*A communication from T. A. Edison, Menlo Park, New Jersey, U.S.*) 4*d*.

The inventor makes his commutator bars and brushes of copper, and amalgamates their surfaces directly with mercury; or they are faced with silver and afterwards amalgamated; this reduces sparks.

3812. AN IMPROVED METHOD OF AND APPARATUS FOR TRANSMITTING SECRET MESSAGES BY ELECTRO-MAGNETIC TELEGRAPH, *W. R. Lake, London.—(A communication from A. F. and F. B. Johnson Brooklyn, New York.)—2nd September*, 1881. 10*d*.

This invention relates to a method of transmitting secret messages by electro-magnetic telegraph instruments over ordinary telegraph wires. The inventors use three instruments; one by which the sender of the message himself prepares it for transmission by means of indentations made by the machine on a strip of paper; a second, which the indented paper passes through, and thereby causes the third or receiving instrument, with which it is connected by ordinary telegraph wires, to operate automatically and receive and print the message. The receiver prints the message in ordinary alphabetical letters whilst it is concealed from view and enclosing and addressing it for delivery. The invention is described at great length, and with detail drawings.

Digitized by Google

THE
SCHOOL OF TELEGRAPHY & ELECTRICAL ENGINEERING.

ESTABLISHED IN 1868.

12, PRINCES STREET, CORNER OF HANOVER SQUARE, LONDON, W.

(Removed from 4, George Street, Hanover Square.)

MANAGING DIRECTOR: Mr. T. J. JONES, M.S.T.E.

The course of Practical and Theoretical Instruction in the higher branches of Overland and Submarine Telegraphy embraces, in addition to the manipulation of he various systems of working in general use, the following subjects:—

MATHEMATICS, MECHANICS, and CHEMISTRY, } In relation to Telegraphy.	SIGNALLING and TESTING INSTRUMENTS. ENGINEERING FORMULÆ and their Application in Practice.	ELECTRO-STATICS. ELECTRO-DYNAMICS. MAGNETISM.	METHODS of TESTING the ELECTRICAL CONDITION of a LINE During and After its Construction. TESTING FOR and LOCALISING FAULTS, &c., &c., &c.

The instruction, both in signalling and testing, is of a thoroughly practical character, as the classes work with the actual instruments used on long lines, through cables of various lengths, from 600 to 3,000 knots, so that the signals of the Eastern, Atlantic, and Brazilian Co.'s, &c., are exactly reproduced, and the pupils fitted for any line.

A complete practical and theoretical course of instruction on the TELEPHONE and the ELECTRIC LIGHT, and their commercial utilisation, has now been added to, and embodied in, the ordinary curriculum, as the advantage of being associated with any great commercial application of science at an early period of its development is one which has been so often exemplified that it can scarcely fail to be appreciated by those who have in view professional success.

That **TELEPHONIC** communication and **ELECTRIC LIGHTING** constitute such applications is sufficiently shown by their rapidly increasing progress; and therefore no pains or expense have been spared to place at the disposal of the pupils the technical and scientific instruction requisite to qualify candidates for the most important posts in connection with these new branches of electrical engineering. In order that the instruction in the erection, adjustment, testing, and working of **TELEPHONE** and **ELECTRIC LIGHT** circuits may also be thoroughly practical, complete working telephone exchanges upon the various systems in use in different countries have been fitted up; every kind of telephone, for both exchange systems and private lines, with all apparatus used therewith, is provided (in duplicate when possible, so that students may be able to dissect and reconstruct the same). The necessary tools and materials are available, and every facility is given for conducting experiments by the pupils desirous of so doing, and a similar course is being pursued with the **VARIOUS LAMPS** and **MACHINES**, &c., in the **ELECTRIC LIGHT** Department, so that pupils from the School are in a position to enter either of these new fields.

The complete Practical and Theoretical course extends over a period of Six Months.

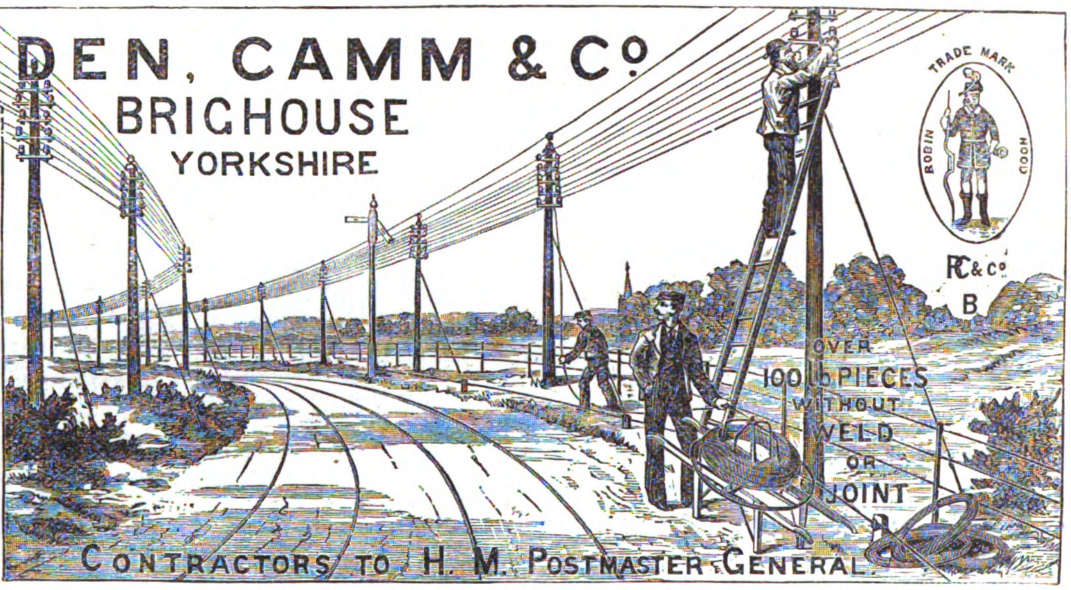
Arrangements have been made so that Inventors, Amateurs, and others can now have every facility, with all necessary apparatus provided in private rooms, to compare, test, or perfect any Inventions, Apparatus, &c., connected with Telegraphy, Telephony, and the Electric Light. Financial and the highest professional assistance can also be had.

Further particulars may be obtained on application to W. N. TIDDY, *Secretary.*

RAMSDEN, CAMM & Co

Manufacturers OF **Patent Telegraph Wire** TO GOVERNMENT SPECIFICATIONS.

Best Refined Telephone Wire,
Fencing Wire,
Submarine Cable Wire,
Strand and Stay Wire,
AND
Galvanised Binding Wire.



London Office: 72, KING WILLIAM STREET, E.C. (GEORGE W. SHARE & CO.)

IMPORTANT TO TELEGRAPH COMPANIES.

THE SANITAS COMPANY (Limited), of Bethnal Green, E., have received the following gratifying letters upon the subject of Sanitas and its uses at Foreign Telegraph Stations:—

"THE MANAGING DIRECTOR, THE SANITAS COMPANY (LIMITED). "February 4th, 1880.

"We have now for more than a year been using your SANITAS soap and disinfectants in our ships, as well as at our stations, and find it greatly appreciated, more especially at tropical places, where the importance of sanitary arrangements is not well understood."

"London, 15th November, 1880.

"I think it right to inform you that our Superintendent at Mozambique says:—'I use the much-prized "SANITAS" freely, and feel perfectly safe wherever I sprinkle it.' "JAMES ANDERSON, Managing Director, Eastern Telegraph Company (Limited), 66, Old Broad-street, E.C."

"SANITAS" DISINFECTING FLUID, No. 1, in 1/- and 2/6 bottles.
"SANITAS" DISINFECTING FLUID, No. 2, in 1/- pints.
"SANITAS" DISINFECTING OIL, @ 30/- per gallon.
"SANITAS" TOILET FLUID, in 1/- and 2/6 bottles.
"SANITAS" DISINFECTING POWDER, in 1/- boxes, and 17/6 per cwt.
"SANITAS" TOILET and NURSERY POWDER, in 1/- boxes.
"SANITAS" TOOTH POWDER, in 1/- boxes.
"SANITAS" DISINFECTING HARD SOAP, No. 1, in 6d. bars.
"SANITAS" DISINFECTING HARD SOAP, No. 2, in 4d. bars.
"SANITAS" SOFT SOAP, in 1/-, 1/9, 3/-, 5/-, 9/-, 12/6, and 24/- sizes.
"SANITAS" TOILET SOAP, in 1/6 boxes of three tablets.
"SANITAS" DISINFECTING FURNITURE CREAM, in 1/- bottles.
"SANITAS" DISINFECTING OINTMENT, in 1/- and 3/6 sizes.
"SANITAS" VETERINARY OINTMENT, in 2/6 tins.

SANITAS is Non-Poisonous and Without Stain, and is used by 400 Public Bodies.

ELECTRICAL.—A Gentleman who has taken high mathematical honours at Cambridge, is a Doctor of Science of the London University in Electricity, a good chemist, and acquainted with the French and German languages, desires an ENGAGEMENT which would occupy the whole or part of his time. Address, Cantab, care of Messrs. E. and F. N. Spon, Scientific Booksellers, Charing Cross.

A GENTLEMAN who thoroughly understands the manufacture, in all its branches, of Incandescent Lamps, is about to start for Australia. He would undertake the SOLE MANAGEMENT of a Company for the manufacture of Incandescent Lamps. Is a good manager and careful buyer. Highest references.
Address, for one week only, "Stone," ELECTRICIAN Office, 396, Strand, W.C.

SLIP

Electric Light in Buda-Pesth.—The post office in this city is lighted by Edison lamps.

New Zealand.—News from this colony reports the splicing of the Cook's Straits cable by the steamer "Agnes."

Dissolution of a Company.—The Société Générale pour l'Utilisation des Forces Electriques, of 9, Rue d'Antin, Paris, has been dissolved.

The Magazines.—Mr. W. H. Preece, F.R.S., continues his contribution to *Time*, this month's article dealing chiefly with the telephone.

Tasmania.—The latest news from this colony reports that about seven miles of telegraph wire had been blown down near Circular Head by a series of heavy gales.

Electric Light In Havana.—The café of "El Louvre," in Havana, Cuba, has been lighted up by Edison lamps. The lights excite considerable curiosity amongst the inhabitants.

Direct Spanish Telegraph Company.—The estimated traffic receipts of this company for the month of June were £1,963, against £1,456 in the corresponding period of last year.

Barbadoes.—The result of the Telegraphic Conference has been submitted to the Legislature, but the report leaves the question pretty much in the *status quo ante.—Colonies and India.*

Electric Light in Shops.—Messrs. Bowron, who are the proprietors of large provision stores in the Edgware-road, W., are going to light up their premises by means of Swan lamps.

Eastern Telegraph Company.—The traffic receipts of this company for the month of June amounted to £46,450, against £40,074 in the corresponding period of 1881, being an increase of £6,376.

Dutch East Indies.—M. A. Brummd has been appointed Chief of Posts and Telegraphs in the Dutch East Indies, vice M. Janssen van Raig, who has been compelled to return to Europe to recruit his health.

Eastern Extension Telegraph Company.—The traffic receipts of this company for the month of June amounted to £31,123, against £29,339 for the corresponding period of 1881, being an increase of £1,783.

Underground Telegraphs in Glasgow.—At the last meeting of the Glasgow Town Council permission was granted to the Post Office authorities to extend the telegraph line underground from Glasgow to Springburn.

West Indies.—The cables between St. Vincent and Grenada, and between Guadeloupe and Dominica, are now repaired; and telegraphic communication is, therefore, restored with all places in the West Indies.

Electric Light in Kendal.—Messrs. G. Gilkes and Co., ironfounders, of Kendal, Westmoreland, recently lit up part of their works with Swan lamps, in order to exhibit its qualities to the Town Council and other residents of the locality.

The Electric Light Bill.—The *Daily News* says: "Though the Electric Light Bill was not mentioned in Mr. Gladstone's category of measures intended to pass this Session, such intention is held, and will probably be carried into effect."

Appointment.—Mr. A. F. A. Hervey, lately in the employ of Messrs. Woodhouse and Ransom, has been appointed engineer to the Australasian Electric Light, Power, and Storage Company (Brush system), and leaves England on the 13th inst.

Electric Light in Antwerp.—Forty-five A, 16 candle, and 40 B, 8 candle, Edison lamps have been established in Messrs. Gits, Segers, and Co.'s sugar refinery at Antwerp. We believe that another of this firm's factories is to be lit by 300 lamps shortly.

The Edison Light in Chicago.—A company has been formed in Chicago under the title of the Western Edison Light Company, and owns Edison's patents for the states of Illinois, Wisconsin, and Iowa. Its head offices are in Wabash-avenue, Chicago.

War Preparations.—A telegraph train is being got ready at Woolwich, in anticipation of hostilities in Egypt. It consists of four telegraph offices, ten wire waggons, carrying thirty miles of wire, four air line waggons, and four Royal Engineer general service waggons.

New Companies.—The Electric "Sun" Lamp and Power Company has a capital of £200,000, and has been formed to work the patent rights of the Lampe-Soleil. Its offices are at 6, Old Jewry, E.C.—The Anglo-Italian Brush Electric Light Company has a capital of £400,000.

Anglo-American Telegraph Company.—The directors of this company have resolved, after placing £37,500 to the renewal fund, to declare an interim dividend for the quarter ending 30th June, 1882, of 15s. per cent. on the Ordinary stock and 30s. per cent. on the Preferred stock.

Lighting for Wimbledon.—The Wimbledon Local Board are asking for tenders for lighting about three hundred of their street lamps with gas *or otherwise* for one year, commencing August 1st. Tenders must be sent to the clerk of the board on or before noon on the 17th inst.

Great Northern Telegraph Company.—The traffic receipts of this company for June amounted to £22,560, against £115,560 for the period from 1st January to 30th June, and £114,966 for the corresponding months of 1881. The receipts for the same period of 1880 were £108,035.

The Sanitas Company.—The directors of this company, after providing for the usual interest at the rate of 5 per cent. per annum on the preference shares, have decided to pay an interim dividend upon the ordinary shares for the half year ending June 30th, 1882, at the rate of 10 per cent. per annum.

New Ship.—On Thursday week Messrs. John Elder and Co., of Glasgow, launched the steel paddle ship "Normandy," which they have built for the London, Brighton, and South Coast and the Western of France Railway Companies. Her gross tonnage is 600 tons. She is handsomely fitted up, and is supplied with electric lights.

Edison's Dynamos.—The dynamos made by the Edison Company are in six sizes, as follow:—E size, for 15 lights; Z, 60 lights; L, 125 lights; K, 250 lights; R, 500 lights; and C, 1,200 lights. The capacities as given above are for A lamps of 16 candle-power, and each machine will generate current for double the number of B lamps of 8 candle-power.

Proposed New Atlantic Cable.—A telegram to the *Daily News*, dated New York, Tuesday, says: "The Senate passed yesterday the Bill granting a charter to the Baltimore and Ohio Railway Company to lay an ocean cable between this country and Europe. It specifies that the Company

Digitized by Google

shall begin to lay the cable within two years of the passage of the Act.

New Company.—The Société l'Eclairage Electrique has been formed in Paris. It has a capital of 6,550,000 francs, and is the result of the merging of the Société Générale d'Electricité, working the Jablochkoff patents, and the Compagnie Générale d'Electricité into one. The new company will work the patents of Gramme, Jablochkoff, and Maxim, the first for his machine, and the two latter for their lamps.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of this company during the month of June was 3,022, estimated to produce £2,900, against 2,757 messages, producing £2,837 in the corresponding month of last year. The traffic receipts for the months of March and April, estimated at £4,000 and £3,800, realised £4,123 and £3,921.

Cuba Submarine Telegraph Company.—The directors of this Company have resolved, after providing for the dividend on the preference shares and placing £3,950 to the reserve fund, to recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax, leaving £2,145 to be carried forward to the current half year's account.

Electric Lighting at Cape Town.—The Edison incandescent lamps, about three hundred in number, which were shipped some months ago to the order of the Cape Town Government, and which have been installed in the House of General Assembly, are reported to have worked admirably without a single hitch, and are giving complete satisfaction. The order was, we believe, executed in England by Mr. W. H. Preece.

An Electric Railway for Turin.—It is intended to hold an Exhibition at Turin in 1884, and in connection therewith an electric railway is to be constructed, running from the Place Carlo Felix to the grounds of the Exhibition. It is proposed to traverse the Course Victor Emmanuel and the Course Massino d'Azeglio del Valentino, and an effort will be made to open it to the public at least four months before the opening of the Exhibition.

Electric Light for Poole (Dorset).—The Town Council of Poole are inviting tenders for lighting the borough by electric lights, or other means, for one or three years, at their option, from the 1st September next. The amount of illuminating power in candles is to be specified in the tender. Specifications giving the conditions as to lighting by gas or mineral oil can be seen and forms of tender obtained at the Town Clerk's Office, Poole. Sealed tenders, marked "Tender for Lighting," are to be sent to the town clerk by the 21st July.

Opposition to the Electric Lighting Bill.—Colonel Makins, M.P., has given notice that on the motion for going into committee on the Electric Lighting (re-committed) Bill he will move—"That the power given to local authorities, under Clauses 5 and 6 and other parts of the Bill, to raise money on the credit of local rates, without the consent of the ratepayers, for the purpose of competing with private capital raised for a like purpose under the sanction of Parliament, is contrary to every principle hitherto recognised by the Legislature, and that no Bill containing such power will be acceptable to this House."

Electric Light for Limerick Harbour.—The Harbour Commissioners of Limerick are inviting tenders for lighting the docks and a portion of the quays by electric light for three years from the 28th August next. A plan and specification can be seen at the office of the harbour engineer between 11 a.m. and 2 p.m. Tenders are to be sent in marked "Tender for Electric Lighting," and addressed to the Secretary, Harbour Commissioners, Chamber of Commerce, Limerick, before noon on the 13th July. Ten and sixpence will be charged for the specification, but this sum will be returned to those tendering.

Church Struck by Lightning.—During a thunderstorm at Liversedge, Yorks., in the latter part of last week, Christchurch, in that town, was struck by lightning whilst the congregation were singing the "Te Deum." A large stone was removed from the tower and the spouting demolished. The building was suddenly filled with flame, and the gas, which during the darkness had been lit, was blown out. A panic ensued, and the congregation (many being children) rushed to the doors to escape. Fortunately no one was hurt, and numbers of the congregation returned and took part in a thanksgiving service, after which the ordinary service was concluded.

The Panama Canal.—According to the report recently presented to the annual meeting of the shareholders of this company in Paris, the telegraph seems to be largely made use of in connection with the works. The report says that stations comprising houses for the engineers, foremen, and workmen have been built on the hills in proximity to the works. Each station is to have its hospital, with forty beds, its telegraph office, its storehouse, and its workshop. A direct line of telegraph has also been established between Colon and Panama, and another line places all the abovementioned stations in communication with each other and the two extremities of the works.

"Induction."—This is the title of a little book by Mr. Willoughby Smith which has just been issued. The title is short and the book small, consisting as it does of but seventeen pages of large print, but the information it contains is most valuable, comprising interesting particulars of the various experiments which led Mr. Smith up to his latest discovery, the inductophone. We merely wish to call attention to this publication now. We shall deal at greater length with Mr. Smith's researches, as recounted by himself, in a future issue, when we shall hope to be able to do the subject the justice which it demands at our hands. The inductophone was illustrated and described in our issue for June 3.

Electric Light for Camberwell.—The Vestry of Camberwell notify that the revised specification for the supply of electric lighting in parts of their parish may be obtained on application to Mr. George W. Marsden, vestry clerk, Vestry Hall, Peckham-road, S.E. The roads proposed to be lighted are Camberwell-road, Church-street, Camberwell; Peckham-road, and High-street, and Queen's-road, Peckham. Tenders are to be for supplying light from sunset to sunrise, for twelve months, from the 2nd of October next. The present gas lamp columns may be used by the contractor, or he may erect special posts of his own, but in carrying out the works no disturbance of the present gas lamps will be allowed. Tenders are to be sent in addressed to the General Purposes Committee, Vestry Hall, Camberwell, before the 17th inst., at four o'clock. Further particulars can be had of Mr. J. C. Reynolds, surveyor to the vestry, at the Vestry Hall, Camberwell.

A Vessel Struck by Lightning.—Particulars have just been received at Liverpool of a remarkable disaster to the

Digitized by Google

vessel "Gertie May." The "Gertie May" was 174 miles from Matinicus on the 18th ult., when she was struck by lightning, which first caught the foretopmast, breaking some three feet off it, then ran to the bow, smashing a portion of the stem; thence to the forecastle, where were ten of the crew in different attitudes, some sitting and some standing. All alike were rendered instantly insensible, but recovered a short time afterwards. The lightning traversed the whole of the vessel, eventually returning to the fore part, where it knocked out two of the vessel's planks in the stem. Fortunately the damage was above the water-line. The vessel had a quantity of salt on board, and this was removed to right her and prevent her sinking. The flag, which was flying on the mainmast, was completely consumed. The "Gertie May" reached Portland on the following day, and lay up for repairs.

Proposed Gas and Electric Light Exhibition.—It has been finally decided by the Crystal Palace authorities to hold this exhibition in the autumn. We have no doubt that representatives of the various electric light systems will be well to the fore in order to show what can be done with their lights, when opposed to gas. If the efforts that will be made by the representatives of the latter method of lighting may be at all gauged by the efforts that are being made by the journals representing their interest, a thoroughly good exhibition of gas lighting should result. Our excellent contemporary, the *Journal of Gas Lighting*, has done its very best to stir up gas people. We shall see what will be the answer to its appeals. The *Journal* thinks that there is some need that gas should be brought before the public in a different garb to that in which it usually appears, so as to give them a chance of seeing what it *can* do. Speaking of the effects of the recent Exhibition, our contemporary thinks that it "did a vast amount of harm among impressionable people; although well-instructed observers of the progress of electrical science failed to see anything new in it. Still, a wide allowance must be made for average human nature, and it is not to be wondered at, by the skilled observer of his kind, that the artful displays of lighting in gorgeously-decorated and furnished rooms appealed more powerfully to the public than any number of learned lectures or published descriptions of Mr. Edison's or Mr. Swan's doings." The *Journal*, therefore, thinks that gas had better go and do likewise. The only question is, when the public have seen what gas *can* do, will they put up with its ordinary performances?

International Electric and Gas Exhibition.—The following notice has been issued by Major Flood Page with reference to this proposed Exhibition:—"The third of the series of International Exhibitions will be opened in the Crystal Palace, Sydenham, in October, 1882, and continued till the end of Easter week, 1883. Applications for space, English and foreign, should be made to the Manager, Crystal Palace, before 1st August, 1882. Their admission and the space assigned to them, together with the regulations, will be notified to exhibitors as soon as is practicable. Printed forms of application for admission can be had from the Manager, Crystal Palace, Sydenham, London. The principal objects to be admitted are comprised in the following: (*a*) Apparatus used for the production and transmission of electricity. (*b*) Magnets, natural and artificial; mariners' compasses. (*c*) Applications of electricity: To telegraphy and the transmission of sound; to the production of heat; to lighting and the production of light; to the service of lighthouses and signals; to apparatus giving warning; to mines, railways, and navigation; to military art; to fine arts; to electro-chemistry, galvano-plastic and chemical arts; to the production and transmission of motive power; to mechanical arts and horology; to medicine and surgery; to astronomy, meteorology, geodesy; to agriculture in its application to industries; to apparatus for registering; to domestic uses; lightning conductors. (*d*) Apparatus connected with the manufacture of gas, and also models. (*e*) Gas apparatus of every kind, and also models. (*f*) Gas engines and also models. (*g*) Cooking by gas. (*h*) Heating by gas. (*i*) Chandeliers, burners, private and public gas lamps."

The St. Gothard Cable.—Our contemporary, the *Journal Télégraphique*, gives some particulars of this cable, from which we extract the following:—"It was manufactured by Messrs. Felten and Guilleaume, at Cologne, and cost 4,750 francs per kilometre, delivered at Basle. The conditions which it was to fulfil were as follow:—There were to be seven conductors, each of which was to be formed of a strand of seven copper wires, each ·7 millimetre in diameter, making the strand itself 1·84 millimetre diameter. The conductivity of these conductors was to be such that the core would offer a maximum resistance per kilometre of seven Siemens units at a temperature of 15° C. The material for insulating each strand was composed of four layers, the first being of Chatterton's compound applied direct to the copper, the second of gutta percha, the third of Chatterton's compound, and the last of gutta percha. This insulation made the diameter of each strand 5·2 millimetres. The resistance which the insulation of each strand was to offer was to be one thousand millions of Siemens units at 15° C, and its minimum electrostatic capacity was to be ·21 of a microfarad. Each strand was wound round with a layer of tarred hemp, which kept the centres of the strands at a distance of seven millimetres from each other. The seven strands thus covered formed a single strand wound in its turn with two layers of tarred hemp, the whole being protected by a covering of ten galvanised iron wires of 4·4 millimetres diameter, and over these was wound a layer of tarred hempen twine three millimetres thick. The cable was to be delivered in sections of 1,000 metres long, so that for the whole length of the tunnel fifteen of these sections were required, and fourteen joints had to be made. The maker was allowed a deviation of 5 per cent. on all these different conditions.

The Telephone at Greenock.—There are at present over seventy subscribers to the Greenock Exchange of the National Telephone Company. The police stations, fire stations, and gas office are also connected, so that in the event of fire, communication with the respective stations can be readily and quickly effected. This exchange has also for some time past been in communication with the same company's exchange at Glasgow by a trunk line which is rented from the post office; the distance between the two exchanges is about twenty-three miles. We believe that a large amount of business is transacted between the two towns by means of this line. Recently, a subscriber to the exchange has had himself put in communication with a church in St. George's-square, as, being an invalid, he is unable to attend service. On the first Sunday on which communication was effected, the Hillhead Exchange, which is two miles from Glasgow, was also switched on to the church, and the service followed by Mr. D. Johnstone Smith, secretary to the Exchange. Mr. Johnstone Smith describes his experiences as follows:—"I distinctly heard the sermon, the text being from the sixth chapter of Hebrews, and the words 'Heirs of promise.' Occasionally I lost a sentence, but, on the whole, it was very perfect; the hymns given out, the organist playing them over, the rustle

Digitized by Google

made by the people rising, the volume of sound by the large congregation singing, every note coming out quite clearly and distinctly, and the whole effect very fine. The benediction (followed by a few moments of quiet) and the rustle made by the people leaving were distinctly heard." The distance between the church and the Hillhead Exchange is about twenty-five miles. The Greenock Exchange has for the last six months been under the able managership of Mr. J. D. Miller.

How Reports are Made.—Professor Silvanus P. Thompson, in a letter written to a Bristol paper, criticises a report by Mr. Kitt, C.E., and Mr. Low, presented by these gentlemen to the Bristol Sanitary Authority, and dealing with the Crystal Palace Electric Exhibition. It appears that these gentlemen stated in their report that "the *arc* lights of the Edison Company were very steady," and that "they appeared to possess an equal amount of illuminating power to those of the Brush Company." Professor Thompson points out that there was not an Edison arc light in the whole Exhibition, and conjectures that the reporters mistook Siemens's or Crompton's lamps for "Edison arc lights." Then these gentlemen seem to have swallowed and recorded the fact communicated to them by an attendant at a stall where eight-candle Edison lamps were burning with sixteen-candle gas burners, that it required a number of the former to compete with the latter. We suppose it did, probably twice the number. They also seem to have thought that in some rooms there were too many electric lights, that Edison machines were "very ugly and unsightly things," and that compared with gas the Jablochkoff system was the cheapest. With reference to the first of these rather novel ideas, Professor Thompson asks, "Does the bad taste of people who overdo the lighting of a room by electricity prove anything more than that the same people would indulge the same bad taste in lighting by gas?" In regard to the second, he asks, "Are there not other things almost as worthy of censure? It will take a great deal to convince most people that a gas retort and a gasometer are more lovely or picturesque," and with regard to the last, he says,—"The system, though a most effective and meritorious system, is perfectly well known to be the least economical of all arc lights. Is it possible that no more recent data, or no data concerning more economical systems, have yet reached official ears?" We have quoted enough from this so-called report to show how extremely little the reporters knew of their subject, and how very unreliable was the information they obtained.

Electric Lighting in the City.—At the meeting of the Commissioners of Sewers on Tuesday last a petition was presented by the Hammond Electric Light and Power Supply Company and the Electric Light and Power Generator Company stating that they had been invited to tender, and had tendered, for the lighting of certain of the thoroughfares of the City. In tendering they had estimated that the lighting would be for one year only, and experimental in its character, and they had therefore been obliged to take into account that part of their plant and materials would be useless at the end of the year, but if the Court gave more permanency of character to the contract, they would be able to make a lower tender. As far as the lighting of shops and warehouses went they could do so by means of running cables into them from the streets. Such lighting was a most remunerative undertaking, and if the Commission thought fit to give to the petitioners and to the ratepayers the right of coming to an agreement with reference to private lighting *en route* they would be in a position to make a tender very much lower than hitherto. The petition was referred to the Streets Committee. A petition was presented at the last Court from merchants and traders asking the Court to grant to the Electric Lighting Companies the right of lighting private houses, shops, and warehouses *en route* and adjacent, and of continuing their contracts for not less than three years, subject to the right of the Commission in the public interest to determine the contracts should they prove detrimental to the public. The Streets Committee had had the matter under consideration, and also the further question whether steps should not be taken to provide that all arrangements in regard to electric lighting within the City, whether of the public ways or private premises, necessitating interference with the pavements, should be undertaken by the Commissioners; and they reported that in their opinion the wishes of the memorialists should be complied with and provided for in any arrangements that might hereafter be considered desirable with respect to the electric lighting of the City, and expressing a strong opinion that that duty should be undertaken by the Commission. The report was referred back for further consideration. Full details of the tenders sent in for lighting the new districts of the City will be given next week.

A Pioneer in Telegraphy.—A correspondent has contributed the following to the daily press:—"Mr. John Watkins Brett and his brother, Mr. Jacob Brett, may unquestionably be designated as the original projectors (if not inventors) of the Submarine Telegraph, for as far back as July, 1845, the Messrs. Brett registered their plan for an oceanic or submarine telegraph, and in the same year took out patents for the construction of subterranean lines. In 1847 they obtained permission from the Government of Louis Philippe to establish a submarine cable between the coasts of France and England, but were unable to obtain any support from the public to carry out the undertaking. In 1849 a concession for the same object was granted to them by Prince Louis Napoleon, then President of the French Republic, and in 1851 the Submarine Telegraph Company was formed, and a substantial cable containing four conducting wires, and protected by a coating of iron wires was laid between Dover and Sangatte, near Calais, and this cable is at the present moment in excellent working condition. Mr. John Watkins Brett became afterwards one of the founders of the Atlantic Telegraph, and also of various telegraph lines in the Mediterranean. He died in 1863, leaving only a moderate fortune to be divided among a numerous family of brothers and sisters. Since that time Mr. Jacob Brett, who is now 74 years of age, has fallen into most serious pecuniary difficulties, and at the present moment is absolutely without a home or any means of supporting himself. A committee, consisting of Sir James Carmichael, chairman of the Submarine Telegraph Company, and other gentlemen interested in telegraphic enterprise, has therefore been constituted to promote the subscription of a fund in aid of Mr. Jacob Brett, to which the Submarine Company have given £200, and an appeal is confidently made on his behalf for further assistance to those companies and individuals, as well as to the public in general, who have derived such great benefits from the establishment of the Submarine Telegraph. It must be remembered that if the earlier experiments of Messrs. Brett had ended in failure the world might have been long deprived of that invention which Lord Granville has so happily termed 'the wonderful instrument of communication of thought.'" Messrs. Ransom, Bouverie, and Co., of 1, Pall-Mall East, have kindly consented to receive any subscriptions that may be sent to them for Mr. Jacob Brett's "Benefit Fund."

HISTORICAL MACHINES.

Soren Hjorth's First Machine.

We have already given some links in the history of magneto and dynamo machines, but hitherto one of the most celebrated of the early machines has not been described in our columns. We have tried to get the specification of this machine, but have always been met with the remark, "out of print." Surely the revenues of the Patent Office are large enough to admit of such specifications being reprinted without loss of time.

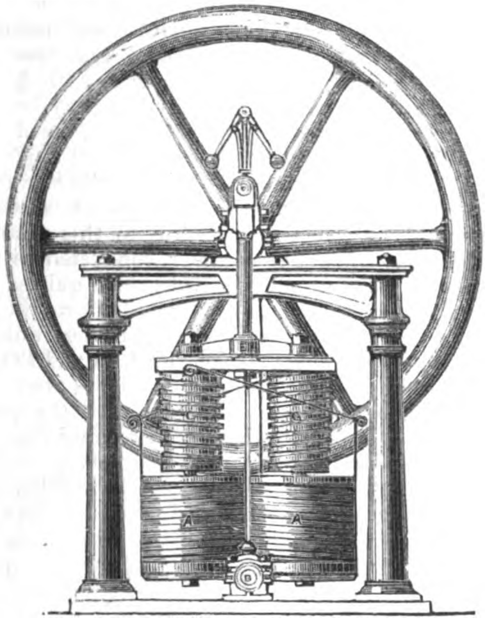

Fig. 1.—Elevation of Hjorth's Engine.

Hjorth described his invention as relating to certain improvements in the use of electro-magnetism, and its application as a motive power for general purposes, also to certain improvements in the application of electro magnetism to

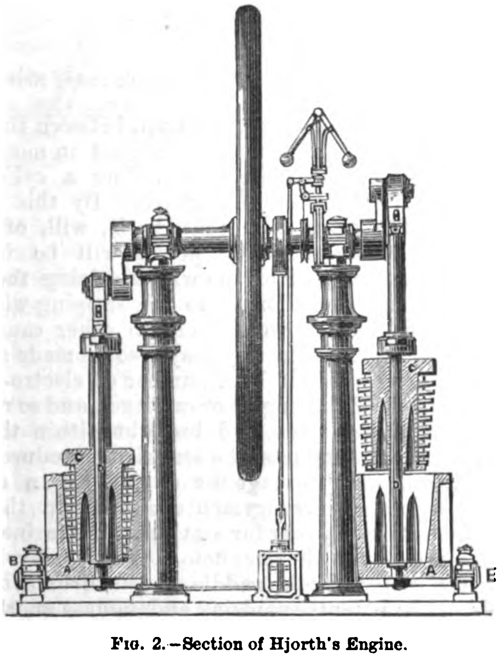

Fig. 2.—Section of Hjorth's Engine.

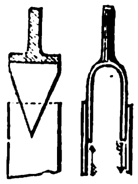
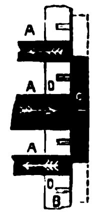
engines, ships, and railways. In the specification the word magnet is used generally to signify either a permanent magnet or an electro magnet. The invention consists in obtaining such power by means of magnets or electro-magnets, both fixed and movable, formed and arranged in such a way that during the motion of the movable magnet, or magnets, separate points or parts of the surface of the movable magnet or magnets, shall be brought successively to act upon, or be acted upon by separate parts of the fixed magnets, so that the attractions and repulsions of one part shall be followed up by the attractions or repulsions of another part, and so a rotatory or reciprocal motion may be obtained over a greater length of stroke or circuit than by the simple action of magnets arranged in the ordinary manner.

Fig. 1 represents an elevation, Fig. 2 a section of one of Hjorth's engines. A A is a horseshoe-shaped hollow magnet, conical on the inside, coiled with copper wire, and suspended so that it oscillates on the centre B, with suitable bearings and plummer blocks as shown. Inside this magnet are fixed a number of conical rods of different lengths. Another horseshoe magnet, C C, is shown, conical outside, with apertures corresponding to the rods in the magnet A A. The magnet C C moves on the guide rods D D connected at the top by the crosshead E, and fastened at the bottom of magnet A A. A connecting rod is attached to C C, driving a fly wheel shaft by cranks in the usual way. A commutator, O, is used similar in its mode of working to the slide valve



Figs. 3 and 4.—Apparatus for Regulating the Current

of a steam engine, and moved in a similar way by an excentric and excentric-rod. The action of the engine may be reversed by the use of a supplemental excentric. The governor serves to regulate the proper supply of current to the commutator as afterwards described. The current from the commutator enters the helix of wires round A A and thence through to the wires of C C, thence through the conducting wires to the battery. As soon as the current passes into the coils they exercise mutual attraction not only in the ordinary way, but in consequence of the magnets being so shaped that the inside part of the outer magnet, as well as the outside part of the inner magnet, form angles with the direction of motion of the moving or the working magnet; and at the same time, rods of different lengths presenting themselves at the poles of the respective magnets, the attractive power is sustained over the whole stroke by successive parts of the surfaces being brought to act upon one another during the whole stroke. When the stroke in this manner has been made by one set of magnets, the current is changed and the other set of magnets are made effec-



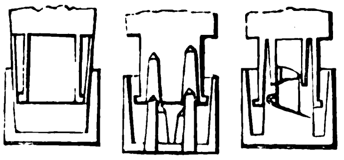


Fig .—The Commutator. Fig . 6, 7, and 8.—Showing various forms of Magnet

tive by the current passing round as previously described. In order to prevent the current being broken, and also to check the momentum of the magnets, the slide in the commutator is made so long that it does not leave the conducting surface, which communicates with one set of magnets, until it has reached the surface communicating with the other set of magnets.

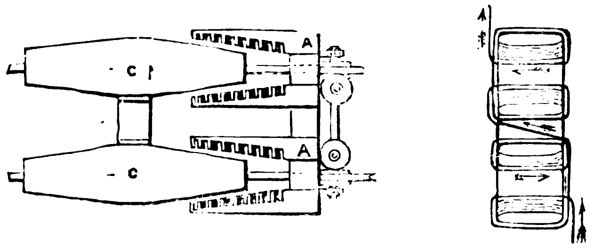
By the arrangement described a reciprocating motion is obtained similar to that of an oscillating steam engine, and the motion can be applied as required by rods, cranks, &c.

Figs. 3 and 4 represent on a larger scale the apparatus for regulating the current. Its action may be understood from the figures. The most convenient form is a forked piece of metal with two wedge-shaped prongs sliding along two parallel surfaces. The current from the battery passes, as indicated by the arrows, from one of the parallel surfaces

Digitized by Google

through the fork to the opposite surface, and hence to the commutator, and the current will pass with greater or less intensity according to the amount of surfaces in contact. The particular form is immaterial, so that taper pieces of metal are used, which, by the ordinary action of the governor, may give greater or less communicating surface.

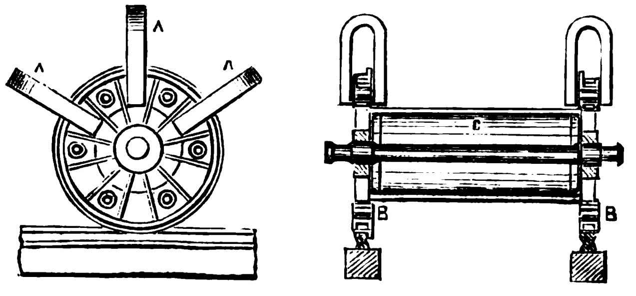
The commutator is shown in Fig. 5 on a larger scale. It consists of three metal surfaces, A, A, A, placed in a non-conducting medium, B. The metal surface, or slide C, is shaped and moved in such a way as to conduct the current according to the motion of the engine alternately from the centre surface, which is connected with the battery to either



FIGS. 9 and 10.—Showing another form of Magnet.

one of the other and outer surfaces, which are connected respectively with the coils of the two sets of magnets. The slide C is made sufficiently long to be always in contact with one or the other surfaces connected with the magnet coils, and by the adjustment of this length and the excentric any required "lead," as it is termed in steam engines, may be obtained. D D is black lead, which may be let into the insulating medium to facilitate conduction, and to act as an anti-friction. The whole apparatus or commutator may be enclosed in an air-tight box, with a glass lid or cover, the slide rod working through a stuffing box. Where large batteries are required for producing sufficient quantity of electricity to work powerful engines, a compound commutator, or several commutators may be employed, each being connected with a certain number of cells, and a certain number of coils. By this means the destruction of the conducting points of the commutator will be avoided, the governor may act so as entirely to detach one or more of the commutators, and so throw off the cells of the battery communicating with such commutators.

Figs. 6, 7, and 8, represent some of the many variations in the form and shape of the magnets, and which may be adopted for the purpose of carrying out my improvements in the use of electro magnetism. In Fig. 6, the coiling of the magnet is surrounded with a sheet-iron casing of a conical



FIGS. 11 and 12.—Showing the method of producing Electricity in an Electro-Magnetic or Common Locomotive.

form, corresponding with the interior of the magnet, in order to obtain a greater attractive surface, and to make the poles of this magnet more effective. Fig. 7 is an enlarged view of the magnets in Fig. 6. In Fig, 8 a long stroke and great attractive surface are obtained by placing a spiral-shaped surface in the interior of the magnet and corresponding grooves or apertures in the magnet. By this arrangement the magnet will act or exercise an attractive power on the successive points of the spiral shaped surface before mentioned, in the same manner as the magnet acts on the rods of different lengths placed in the magnet in Fig. 6. Fig. 9 represents a horse-shoe magnet, each leg of which is divided into two pieces inclined on the inside, and with grooves inside to receive the wires, which are coiled as shown in Fig. 10, the current passing in the direction indicated by the arrows. The magnet is in this case not coiled with wires, being a permanent magnet. The patentee does not confine himself to the use of wrought iron in the magnets or armatures, which may be made of cast iron, or other metals, or substances, which may be made magnetic. It will also be obvious, that the repulsive as well as the attractive powers of metals, or other substances, may be rendered available for the same purposes by means of apparatus constructed and arranged in a manner similar to that herein described. The motive power obtained by the arrangements above described may be employed for all purposes in which power may be required, by the addition of the ordinary apparatus used for such purposes. Thus, the power may be rendered applicable for raising weights, and especially for raising the ram of a pile-engine, or a heavy hammer. In these cases it is intended to apply a magnet, constructed according to this arrangement, immediately over the ram or hammer, connected with it by a web chain or rope, and moving with it in guides. On the side of the frame or guide, adjusting tappets would be fixed, by means of which the connection with the battery would be cut off at any required portion of stroke. Figs. 11 and 12 represent an arrangement by which magneto-electricity is produced in an electro-magnetic or common locomotive, for the purpose of magnetising the wheels, and thereby increasing the adhesion. An are horseshoe-formed permanent magnets, placed so that the inside part of their poles face a certain number of pieces

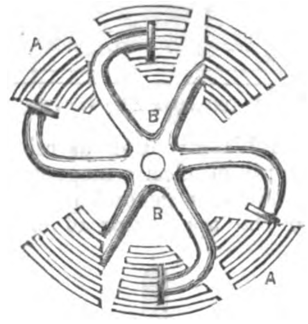


FIG. 13.—Showing an arrangement for obtaining Rotary Motion.

of soft metal, or electro-magnets, B, fixed between the spokes of the wheel. As soon as the wheels are set in motion electricity is induced in the coils surrounding a cylinder, of sheet iron, C, fixed between the wheels. By this arrangement the cylinder, as well as the wheels, will, of course, be magnetic, and the magnetic power will be increased in proportion to the speed of the wheels, giving thereby an increased adhesion proportionate to the slipping which may take place from want of weight or any other cause. The electricity produced in this way may also be made available for moving the engine itself by a number of electro-magnets fixed to the wheels of the engine or carriages, and so revolving by the motion of the train, and brought within the action of fixed permanent magnets, the electricity produced being conducted to the electro-magnetic engine as an auxiliary power. By means of arrangements similar to those just described, an auxiliary power for stationary or marine engines may be obtained from the magneto-electricity developed by the revolution of fly-wheels, paddle-wheels, drums, or working-wheels. The patentee explains and figures another form of commutator, or current changer, as applicable either to the oscillating class of engines or to ordinary reciprocators. To the centre shaft in each set of magnets is attached, at right angles to it, an upright vertical lever, formed with two cross arms, at the end of each of which is placed a syphon cap, similar to those ordinarily used for lubricating purposes. Immediately beneath the discharging tubes of these lubricators, two metallic springs are attached to two pieces of wood, and these springs are adjustable to suit the "lead" required by a set screw, and serve as conductors from the battery to the

Digitized by Google

magnetic coil. The two levers and springs act for the back and forward movements of the engine, and each spring is so set that the end of the lever is brought into contact with it just before the engine crank reaches its top centre. By this means the electric current from the battery is conducted from the spring to the levers, and so to the magnetic coil, and the power of the engine is excited for the down stroke on the side in question. A corresponding action takes place in the springs and levers connected with the opposite set of magnets. During the forward motion of the engine, the first spring is kept completely clear of the motion of the lever, by means of a tappet or cam, or any ordinary mechanical arrangement. A corresponding arrangement is adapted to the other spring, and in working the engine the two tappets or cams may be worked by one handle, so that one spring shall be depressed out of the way, and the other released into action, and thus the motion of the engine be reversed. In order to avoid the spark, and to facilitate the communication of the electric current from the springs to the levers, diluted sulphuric acid is constantly allowed to drop from the syphon cups, through the tubes, by means of a wick, to moisten the surface in contact. A similar arrangement being applied on the other side of the engine, and the springs adjusted so that the touching point or surface of the lever on one side of the engine does not leave the corresponding spring before communication is established on the other side of the

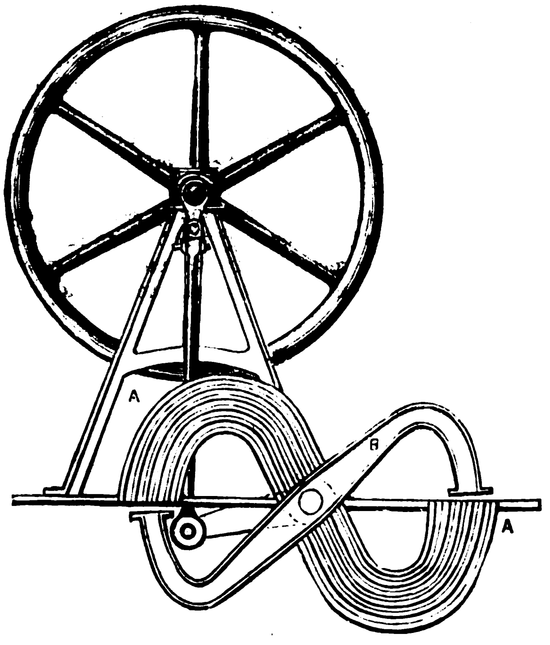

FIG. 14.—Showing method for obtaining Semi-Circular, or Reciprocal, Rotary Motion.

engine, the same result is obtained as has already been described in the other form of commutator. Fig. 13 represents a side elevation of an arrangement by which a rotary motion, with a constant and direct pull, and succession of polarities can be obtained, being one of the modes in which this invention can be applied in and for the construction of a rotary engine. A A are the stationary magnets, here represented as rods of different lengths, put together in such a way that they form a case, with a slit towards the centre for the arms of movable magnets, BB. The said rods are to be fixed in such a way that they do not touch one another, and their ends or surfaces form angles with the direction of motion of the movable magnets. These are to be placed at such a distance from one another, and in such a way that one set of magnets commences to exercise its power before the current passing round or through the other is broken, in order that a constant flow of electricity may be maintained without the current from the battery being broken. The change of the current can be produced by a modification of the common arrangements of a cylinder of metal worked by the shaft, and inlaid with some non-conducting material, from which the conducting wires extend to the coils surrounding the magnets. Fig. 14 shows how a semi-circular motion, or a reciprocal rotary motion, can be obtained, which may be converted into a rotary motion by cranks. A is the stationary, and B the movable magnet. The poles of the stationary magnet form cases, the interior sides of which, or their poles, if built of several bars, form angles with the direction of motion of the movable magnet. In the said cases may be placed rods of different lengths, with corresponding apertures in the movable magnet. The current may be broken in the same way as described in the oscillating engine represented in the engraving. Two sets of magnets will be ordinarily required, working in opposite directions.

Claims.—First: I claim the constructing, arranging, and combining magnets in such a way that they exercise their attractive or repulsive power mutually, by a continuous and direct attraction or repulsion upon points presenting themselves successively during the whole stroke in and for the production of motive power by means of electro-magnetism.

Secondly: I claim the regulating the current of the electric fluid by allowing the same to pass through bodies with surfaces of different dimensions touching or rubbing upon one another in such a way that the areas of the said surfaces are diminished or increased by being moved by a governor, thus allowing a greater or smaller supply of the electric fluid to pass, according to circumstances, in and for the production of motive power by means of electro-magnetism.

Thirdly: I claim the changing the direction of the current by means of a commutator constructed as above described in the use and application of electro-magnetism as a motive power.

Fourthly: I claim the use of electro-magnets adapted to and in combination with engines and carriages on railways, as above described, for the purpose of increasing the adhesion of the wheels, and as an auxiliary power for magnets on railways or stationary and marine engines, as before described.

Fifthly: I claim the arrangements before referred to for producing a rotary motion by a direct pull or thrust, and continual succession of polarities, as above described.

Sixthly: I claim the arranging and combining magnets constructed as described, so that a semi-circular motion or a reciprocal rotary motion of the movable magnet may be obtained, and the power transferred thence, either directly to the work or through cranks and connecting rods, to a revolving shaft.

Lastly: I claim the combining the several arrangements before described and referred to for the application of electricity as a motive power to engines, ships, and railways.

THEORY OF MAGNETO AND DYNAMO MACHINES.

XVII.

It is now time to discuss the rotation of an actual armature in a magnetic field, and we will for this purpose select the Siemens to begin with. It is usual to consider the Gramme as the simplest form of armature, and certainly its construction and mode of action is very easily intelligible; while Von Hefner Alteneck's ingenious method of winding the Siemens armature is understood by comparatively few. Nevertheless, the theory of the Siemens is in one important respect simpler than that of the Gramme, viz., that its core of iron, though helpful, is not necessary; while the iron in the Gramme, as in the old Pixii, Clark, and Saxton machines, is an absolutely indispensable condition of its action.

Now the introduction of iron into the theory, though it must be made at a later stage, is best deferred, because all manner of secondary and complicated actions are with it introduced, unless indeed the iron may be regarded as perfectly non-conducting and infinitely "soft."

A method of classifying the numerous machines of the present day is much needed, but, as is the case with other

Digitized by Google

subjects, the best system of classification depends upon what its object is.

The historian would try to arrange them in order of development, something after the fashion of a family tree, so as to enable their relationships, and the ways in which they shade off into one another, to be traced; and this would be an extremely useful, though somewhat controversial and invidious method.

The common rough and ready system is to divide them into magneto and dynamo; continuous and alternating. But these divisions are too obvious to need further insisting on.

The shareholding public classify them according to the companies who respectively possess them, and according to their market value. The inventors, we suppose, have the simple, satisfactory, and exhaustive classification, into—mine and other people's.

For our present purpose we require a purely scientific arrangement, and we will try how it answers to divide them first into two classes—those which essentially require iron in their armatures, and those which do not. A further bifurcation may be made by arranging them into those which will work in a simple uniform magnetic field, like the earth's, and those which require a more complex and artificial arrangement of magnets. The high E.M.F. and alternating machines mostly come under this latter head.

There is no need to express an opinion as to the *à priori* merits of the four columns so obtained—each has advantages for particular purposes—nevertheless, just as we consider that the great improvement of Siemens's old armature over the Clark and Saxton form was the shaping and arranging it in such a way that its iron core was a useful auxiliary instead of a necessity, so we hold that any machine in which iron is an essential requisite has the burden of proving that it is a better machine than one which is able to do without it. But we do not assert that it could not make out a good case. For instance, the De Meritens is an undoubted improvement on the Holmes-Alliance.

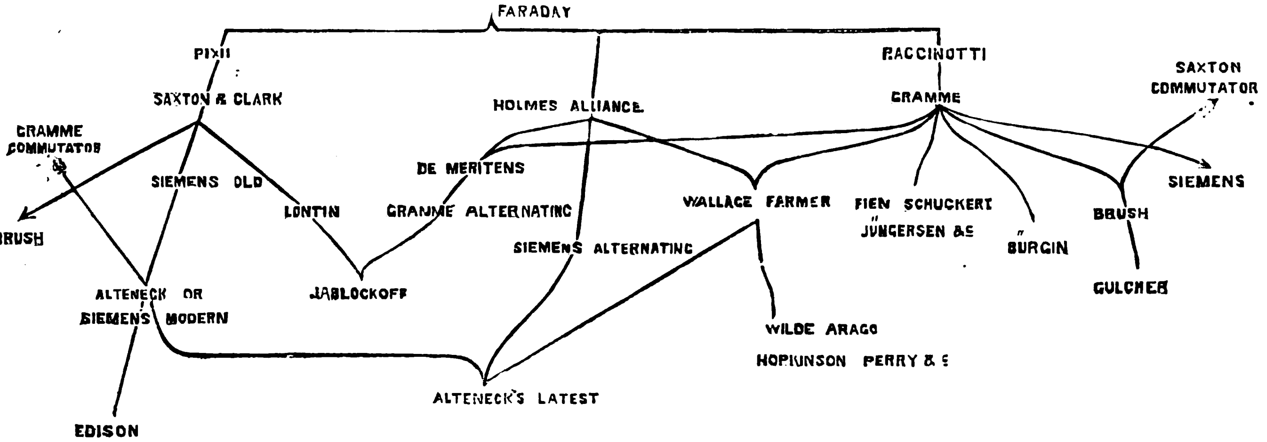
The following table, considered as a list of machines, does not pretend to be complete; it contains most of the better known ones, but it may easily be extended by anybody who will take the trouble to write the names of additional machines in their appropriate columns:—

Classification of Magneto and Dynamo Machines.

Machines which will work in a simple uniform magnetic field.		Machines which require a more complex arrangement of field magnets.	
Machines which can act without an iron core in their armatures.	Machines in whose armatures iron is essential.	Machines which can act without an iron core in their armatures.	Machines in whose armatures iron is essential.
Faraday's original copper disc. Siemens's old form. Siemens's modern. Lontin. Edison.	Pacinotti. Gramme. Brush. Bürgin. Fein. Schuckert. Jürgensen. Gülcher.	Holmes-Alliance. Wallace-Farmer. Wilde. Siemens's alternating. Arago. Hopkinson and Muirhead. Perry. Von Alteneck's newest form.	Pixii. Saxton and Clark. De Meritens. Gramme alternating. Jablochkoff.

Of course the division into "continuous current" and "alternating" remains as a fundamental one, but the division into "magneto" and "dynamo" is scarcely of so much importance, for any continuous current machine may be made self-exciting, and no alternating machine has yet been made so. The division again into shunt dynamos and ordinary dynamos is a mere detail, though undoubtedly it is of great practical importance, and though the theory of the two is considerably different. The alternating machines in the above list are: Holmes, De Meritens, one Siemens, one Gramme, one Lontin, one Hopkinson, and Jablochkoff; and all these are necessarily "magneto," in the sense that they either use permanent magnets or require a separate exciter. The others are continuous current machines, and are usually self-exciting. It is a question whether the Gülcher ought not to go into the fourth column instead of the second, but it seems a pity to separate it from its congeners on account of a mere doubling of the parts.

Table of Affinities of Magneto and Dynamo Machines.



The above table sometimes fails to show the relationships between the different machines, and if we venture to draw up another with this object, it is with a proper sense of the difficulty of the task, and the considerable chances of error and incompleteness. However, here is an attempt. It is supposed to be wrapped round a cylinder, in order to avoid too great crossing of the lines of relationship. These lines, it must be remembered, do not assert parentage; they merely imply a sufficient likeness to justify a presumptive relationship without evidence to the contrary.

(TO BE CONTINUED.)

VAN RYSSELBERGHE'S TELEPHONIC SYSTEM.

We recently alluded to the fact that M. Van Rysselberghe, head of the Meteorological Observatory at Brussels, had succeeded in sending a telephonic message over a long length of ordinary telegraph wire at the same time that a telegraphic message was being sent over the same wire, and that both messages had been distinctly received. Our contemporary, *La Nature*, recently published an account of the way in which M. Van Rysselberghe overcomes the effects of induction, from which we extract the following particulars:—Fig. 1 represents a telegraph and telephone line running parallel to one another, with the ends of the wires to earth, as in ordinary telegraph lines. Each time that the key M is depressed a current is sent to line, which is almost instantaneously charged, all neighbouring wires—and in this particular case the telephone wire—are traversed by a strong induction current of short duration. The same phenomenon

Digitized by Google

occurs, but in an inverse sense, when the circuit is broken. This series of strong induction currents of short duration produces in the telephones a kind of crackling, or frying noise (*friture*), which is the more objectionable the more telegraph wires there are, up to a point when receiving is often impossible.

Supposing that we can, by some method or other, graduate the induction current, so that it shall only attain its full strength bit by bit, the induced currents developed in the telephonic circuit will be prolonged over a longer period, but will be less intense. The action on the receiving diaphragm will also be progressive, and will produce scarcely any sound at all. In fact we shall have replaced violent and instantaneous attraction by a series of weak and successive impulses. To weaken the electric wave of induction, and to suppress the crackling noise produced thereby if not weakened, M. Van Rysselberghe employs various methods. We shall describe two of these which have given good results.

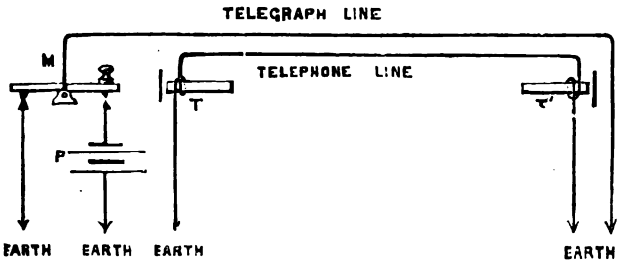


Fig. 1.—Connections of a Telegraph and Telephone Line, showing the cause of induction.

One of them consists in employing keys provided with adjustable rheostats arranged so that when the key lever is depressed there are introduced into the circuit, between the battery and the line, resistances varying progressively from infinity to zero. These rheostats are constructed of mediocre conductors, on which rubs a brush fixed to the key lever. The line is thus charged bit by bit, and comparatively slowly, since the intensity of the current varies with the resistance interposed during the depression of the key lever, and the effects of induction are not sufficiently strong to interfere with telephonic transmission. This transmission on a distinct circuit can be carried on either by means of magneto telephones, battery telephones, or microphonic transmitters.

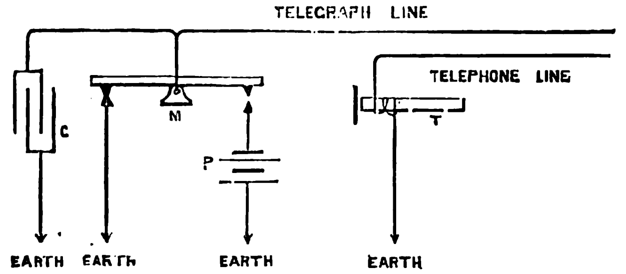

Fig. 2.—Connections of a Telegraph Line, with Condenser, in a shunt circuit, in order to overcome the effects of induction in the Telephone Line.

A second method employed by M. Van Rysselberghe allows of the suppression of induction without in any way altering the arrangement of the key lever. It consists in placing a condenser, C (Fig. 2), in a shunt circuit, as shown. At the moment when the circuit is closed, the electric flow divides between the condenser and the line; this latter, therefore, only takes its charge progressively. The desired result is also obtained in a certain degree by combining the two methods; that is to say, the key with variable resistances and the condensor in a shunt circuit. By this means the effects of induction are quite overcome. It is this combination which gives the best results in practice.

In addition to the above described methods of overcoming induction, M. Van Rysselberghe has introduced several improvements into his telephones which enable him to transmit over long distances. We shall hope to be able to illustrate his apparatus before long.

In the above figures the letter P stands for battery and T for telephone.

ON THE GRADUATION OF GALVANOMETERS FOR THE MEASUREMENT OF ELECTROMOTIVE FORCES AND CURRENTS IN ABSOLUTE MEASURE.

BY THOMAS GRAY, B.SC., F.R.S.E.

Recent developments in the applications of electricity have rendered a class of instruments necessary which were previously seldom required, namely, instruments for the purpose of measuring in absolute units the quantity of electricity flowing through an electric circuit, and the electromotive force producing that current. Having been engaged in determining the constants necessary for the graduation in absolute measure of Sir William Thomson's new galvanometers, it has occurred to me that a discussion of one or two of the methods which may be followed in such a case may be interesting and useful to some of the readers of *The Electrician.*

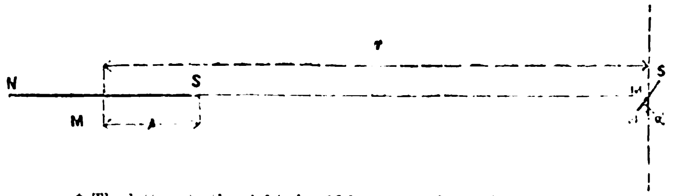
As is well known, the value of the indications of a galvanometer depends on the intensity of the magnetic field in which the needle is placed, on the current flowing through the coil, on the shape, size, and number of windings in the coil, and on some function of the angle through which the needle is deflected. In order, therefore, that the value in absolute units of the indications of a galvanometer may be estimated, we require to determine in the same units the intensity of a magnetic field, and, either separately or as a whole, the value of the different elements depending on the coil. We will employ in the calculations of this article the centimetre as the unit of length, the gramme as the unit of mass, and the second as the unit of time.

With regard to the magnetic field it is generally convenient to use, as our standard at least, the horizontal intensity of the earth's magnetic field at the place of experiment, this being more uniform, and consequently more easily determined than any artificial field we can readily produce. Let us begin, then, by determining in C G S units the intensity of the horizontal component of the earth's magnetic force. The following method will be found sufficiently accurate for almost any purpose, and at the same time easily used. Manufacture three or four small magnets, say ten centimetres long and one millimetre in diameter, out of glass-hard tempered steel wire. Measure accurately the length in centimetres and the weight in grammes of each of these magnets. Suspend one of them within a glass shade by means of a single silk fibre about thirty centimetres long, so that its magnetic axis is nearly horizontal. The easiest way to manage this is to form a double loop on the end of the silk fibre and place the magnet within these two loops in such a manner that the loops and magnet form the three sides of a triangle. When this method is adopted the calculations are not complicated by the inertia of a supporting cradle, the one used being practically massless. Draw a fine line on the sole plate on which the shade stands and set up a fine vertical mark at the end of this line nearest the observer. A fine line scratched on the glass, for instance, serves very well for this purpose. Turn the sole plate and shade round until the magnet hangs exactly in the plane of these two lines, and then deflect the magnet slightly by bringing another magnet forward towards it, taking care to keep its length at right angles to the length of the suspended magnet, and in a line passing through the centre of that magnet. If this precaution is not attended to the suspended magnet gets up a pendulum swing, which interferes with our observations. When the amplitude of vibration reaches about five degrees note the time at which the magnet crosses its position of equilibrium as marked by the vertical and horizontal lines just described. Again note the time at which the magnet crosses the same position, after, say, ten complete vibrations, and again after twenty and thirty, until the amplitude of vibration becomes too small to allow of the exact instant of crossing to be accurately observed. These separate observations will form a check on each other, and the total interval between the first observation and the last divided by the number of complete periods will give the period of one vibration. By a complete vibration is meant a swing from the centre to one side, then back to the other side, and then to the middle again. Repeat this experiment until each suc-

Digitized by Google

cessive experiment gives very nearly the same result. Irregularities are certainly due to errors of observation, and hence irregular results must be discarded. The time may be taken by means of a good watch, and it is better to have a second observer for this purpose. An expert observer will take time to the tenth part of a second, especially if provided with a watch having a centre-seconds hand, and the dial divided to quarter seconds. None of the contrivances for stopping and starting a watch, or for marking on the dial are to satisfactory as single observation, accuracy in which can be readily acquired by a little practice. Repeat this experiment with each of the magnets. The reason why separate magnets are recommended for the different experiments is that errors in the measurement of length and mass are thus to some extent eliminated. Of course no account is here taken of the very small, but in certain circumstances necessary for air friction, change of inertia due to air dragged along with the magnet, want of perfect flexibility in the fibre, and possible changes of magnetic moment, due to slight changes of temperature during the observations. Next place in the position where the needles were vibrated a magnetometer, which had better consist of a very short, light magnetic needle, rigidly fixed to a light mirror, and suspended by a single silk fibre, as in Thomson's reflecting galvanometer. Arrange a scale in front of the mirror, and, if convenient, at a distance of one metre from it. The deflection of the mirror on one side or other of its position of equilibrium may be observed by means of this scale either by a beam of light from the mirror focussed on the scale, as is usual with Thomson's instruments, or by observing the reflection of the scale in the mirror by means of a telescope. Having completed these arrangements, observe the zero position of the mirror, and then place at a measured distance from the magnetometer

FIG. 1.*



* The letters to the right should be *m*, *n*, *s*, instead of M, N, S.

needle one of the magnets which were vibrated, the direction of the axis of the magnet being at right angles to the magnetic meridian, and the centre of the axis either vertical above or below the centre of the needle, or due north, south, east, or west of it. Observe, now, the angle through which the magnetometer needle has been turned, then reverse the positions of the ends of the magnet, and again observe the deflection from zero of the magnetometer needle. Make a similar pair of observations with the magnet on the opposite side, and at the same distance from the magnetometer needle, and take the mean of the four observations, and half the distance between the two positions of the centre of the magnet as the deflection and distance respectively. It must be borne in mind that the angle turned through by the needle is half the angle turned through by the beam of light reflected from the mirror. As to the best relative positions of the magnetometer needle and deflecting magnet it may be remarked that the most symmetrical position is when the centre of magnet and needle are in the same vertical line. The next best, and generally more convenient, position is when the magnet is east or west of the needle, and this is the position adopted in the calculations given below, and illustrated in Fig. 1.

In this figure m represents the magnetometer needle and M the deflecting magnet, placed with its centre at a distance, r, from the centre of the needle m, the length of the magnet being supposed equal to $2a$, and the angle through which it deflects m equal to α. If it is inconvenient to measure the angle α by means of a mirror, and great accuracy is not required, a light index may be attached to the needle and its deflection observed on a graduated scale placed beneath it. The angle α is to be observed for each of the magnets which were vibrated, and then from each set of observations a value of H, the horizontal component of the earth's magnetic force, calculated. If the different values of H thus found are nearly the same, then the mean will probably closely approximate to the true value. The calculation is made in the following manner:—

First from vibration:—

Let H = the horizontal component of the earth's magnetic force.

M = the magnetic moment of one of the magnets experimented on.

T = its period of vibration.

$2a$ = its length in centimetres.

w = its weight in grammes.

μ = its moment of inertia round the suspending fibre.

θ = its inclination at any instant to the magnetic meridian.

We have then the angular acceleration towards its position of equilibrium in the magnetic meridian equal to the moment of the return couple acting on it divided by the moment of inertia μ of the magnet, or in symbols

$$\frac{d^2\theta}{dt^2} = -\frac{\mathrm{M\,H}}{\mu}\sin.\theta.$$

Now, since we have only to do with small values of θ, we may put sin. $\theta = \theta$, and we get the much simpler equation

$$\frac{d^2\theta}{dt^2} + \frac{\mathrm{M\,H}}{\mu}\theta = 0.$$

The integral of this equation is

$$\theta = \mathrm{A}\cos.\left(\sqrt{\frac{\mathrm{M\,H}}{\mu}}\,t - \mathrm{B}\right),$$

which represents an oscillatory motion of amplitute A and period $2\pi\sqrt{\frac{\mu}{\mathrm{M\,H}}}$.

Hence $\mathrm{T}^2 = \frac{4\pi^2\mu}{\mathrm{M\,H}}$, and therefore,

$$\mathrm{M\,H} = \frac{4\pi^2\mu}{\mathrm{T}^2}. \quad \ldots\ldots \quad (1)$$

Second, by deflection, see Fig. 1:—

Let α = the deflection of the magnetometer needle.

f = the strength of one pole of the needle.

l = the length of the needle.

F = the strength of one pole of the magnet M.

$2a$ = its length.

r = the distance of its centre from the centre of the needle.

Then

$$\mathrm{F}f\left\{\frac{1}{(r-a)^2} - \frac{1}{(r+a)^2}\right\} l\cos.\alpha = \mathrm{H}f\sin.\alpha.$$

$$\because \quad \frac{4\,\mathrm{F}\,a\,r}{(r-a)^2\,(r+a)^2} = \mathrm{H}\tan.\alpha.$$

Now $2\,\mathrm{F}a = \mathrm{M}$; hence

$$\frac{2\,\mathrm{M}\,r}{(r+a)^2\,(r-a)^2} = \mathrm{H}\tan.\alpha,$$

or

$$\mathrm{M} = \frac{(r-a)^2\,(r+a)^2\,\mathrm{H}\tan.\alpha}{2\,r}.$$

Substituting this value of M in equation (1), we get

$$\mathrm{H}^2 = \frac{8\pi^2\mu\,r}{\mathrm{T}^2\,(r-a)^2\,(r+a)^2\tan.\alpha}. \quad .\;.\;(2)$$

Since the length of the magnet is supposed great in comparison with its thickness, μ will be nearly enough equal to $\frac{1}{3}wa^2$; hence we obtain finally

$$\mathrm{H} = \frac{\pi\,a\sqrt{8\,w\,r}}{\mathrm{T}\,(r-a)\,(r+a)\sqrt{\tan.\alpha}}.$$

(TO BE CONTINUED.)

FIRE RISKS FROM ELECTRIC LIGHTING.

The following rules and regulations for the prevention of fire risks arising from electric lighting have been recommended by the Council of the Society of Telegraph Engineers and of Electricians, in accordance with the report of the committee appointed by them on May 11, 1882, to consider the subject:—

The members of the committee were—Professor W. G. Adams, F.R.S, vice-president; Sir Charles T. Bright, T. Russell Crampton, R. E. Crompton, W. Crookes, F.R.S.; Warren De la Rue, D.C.L., F.R.S.; Professor G. C. Foster, F.R.S., past president; Edward Graves, J. E. H. Gordon, Dr. J. Hopkinson, F.R.S.; Professor D. E. Hughes, F.R.S., vice-president; W. H. Preece, F.R.S., past president; Alexander Siemens, C. E. Spagnoletti, vice-president; James N. Shoolbred, Augustus Stroh, Sir William Thomson, F.R.S., past president; Lieut.-Colonel C. E. Webber, R.E., president.

These rules and regulations are drawn up not only for the guidance and instruction of those who have electric lighting apparatus installed on their premises, but for the reduction to a minimum of those risks of fire which are inherent to every system of artificial illumination. The chief dangers of every new application of electricity arise mainly from ignorance and inexperience on the part of those who supply and fit up the requisite plant. The difficulties that beset the electrical engineer are chiefly internal and invisible, and they can only be effectually guarded against by "testing" or probing with electric currents. They depend chiefly on leakage, undue resistance in the conductor, and bad joints, which lead to waste of energy and the production of heat. These defects can only be detected by measuring, by means of special apparatus, the currents that are, either ordinarily or for the purpose of testing, passed through the circuit. Bare or exposed conductors should always be within visual inspection, since the accidental falling on to or thoughtless placing of other conducting bodies upon such conductors might lead to "short circuiting" or the sudden generation of heat due to a powerful current of electricity in conductors too small to carry it. It cannot be too strongly urged that among the chief enemies to be guarded against are the presence of moisture and the use of "earth" as part of the circuit. Moisture leads to loss of current and to the destruction of the conductor by electrolytic corrosion, and the injudicious use of "earth" as a part of the circuit tends to magnify every other source of difficulty and danger. The chief element of safety is the employment of skilled and experienced electricians to supervise the work.

I. The Dynamo Machine.

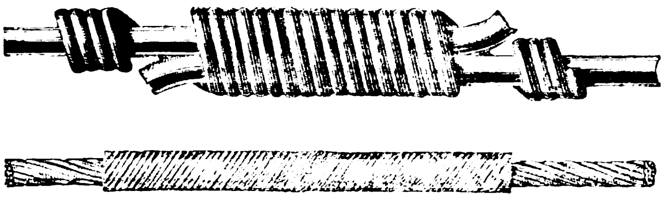
1. The dynamo machine should be fixed in a dry place.
2. It should not be exposed to dust or flyings.
3. It should be kept perfectly clean and its bearings well oiled.
4. The insulation of its coils and conductors should be perfect.
5. It is better, when practicable, to fix it on an insulating bed.
6. All conductors in the dynamo room should be firmly supported, well-insulated, conveniently arranged for inspection, and marked or numbered.

II. The Wires.

7. Every switch or commutator used for turning the current on or off should be constructed so that when it is moved and left to itself it cannot permit of a permanent arc or of heating, and its stand should be made of slate, stoneware, or some other incombustible substance.
8. There should be in connection with the main circuit a safety fuse constructed of easily fusible metal which would be melted if the current attain any undue magnitude, and would thus cause the circuit to be broken.
9. Every part of the circuit should be so determined that the gauge of wire to be used is properly proportioned to the currents it will have to carry, and changes of circuit, from a larger to a smaller conductor, should be sufficiently protected with suitable safety fuses, so that no portion of the conductor should ever be allowed to attain a temperature exceeding 150 deg. F.

N.B.—These fuses are of the very essence of safety. They should always be enclosed in incombustible cases. Even if wires become perceptibly warmed by the ordinary current, it is a proof that they are too small for the work they have to do, and that they ought to be replaced by larger wires.

10. Under ordinary circumstances complete metallic circuits should be used, and the employment of gas or water pipes as conductors for the purpose of completing the circuit should in no case be allowed.
11. Where bare wire out of doors rests on insulating supports it should be coated with insulating material, such as india rubber, tape, or tube, for at least two feet on each side of the support.
12. Bare wires passing over the tops of houses should never be less than seven feet clear of any part of the roof, and they should invariably be high enough, when crossing thoroughfares, to allow fire escapes to pass under them.
13. It is most essential that the joints should be electrically and mechanically perfect. One of the best joints is that shown in the accompanying sketches. The joint is whipped around with small wire and the whole mechanically united by solder.
14. The position of wires when underground should be efficiently indicated, and they should be laid down so as to be easily inspected and repaired.
15. All wires used for indoor purposes should be efficiently insulated.
16. When these wires pass through roofs, floors, walls, or partitions, or where they cross or are liable to touch metallic masses like iron girders or pipes, they should be thoroughly protected from abrasion with each other or with the metallic masses, by suitable additional covering; and where they are liable to abrasion from any cause or to the depredations of rats or mice, they should be efficiently encased in some hard material.
17. Where wires are put out of sight, as beneath flooring, they should be thoroughly protected from mechanical injury, and their position should be indicated.



N.B.—The value of frequently testing the wires cannot be too strongly urged. It is an operation skill in which is easily acquired and applied. The escape of electricity cannot be detected by the sense of smell as can gas, but it can be detected by apparatus far more certain and delicate. Leakage not only means waste, but in the presence of moisture it means destruction of the conductor and its insulating covering by electric action.

III. Lamps.

18. Arc lamps should always be guarded by proper lanterns to prevent danger from falling incandescent pieces of carbon, and from ascending sparks. Their globes should be protected with wire netting.
19. The lanterns and all parts which are to be handled should be insulated from the circuit.

IV. Danger to Person.

20. To secure persons from danger inside buildings, it is essential so to arrange the conductors and fittings that no one can be exposed to the shocks of alternating currents exceeding 60 volts; and that there should never be a difference of potential of more than 200 volts between any two points in the same room.
21. If the difference of potential within any house exceeds 200 volts, whether the source of electricity be external or internal, the house should be provided outside with a "switch," so arranged that the supply of electricity can be at once cut off.

By order of the Council,

F. H. Webb, Secretary.

Offices of the Society, 4, The Sanctuary, Westminster,
June 21, 1881.

Eastern Telegraph Company.—This company announce that, subject to the final audit, the accounts show, after placing the sum of £75,000 to the reserve fund, a balance available for dividend which will enable the directors at the general meeting to pay the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum, on the preference shares, and recommend the payment of a final dividend of 2s. 6d. per share, with a bonus of 1s. per share, on the ordinary shares, both free of income-tax, making with previous payments on account a dividend for the year ending the 31st of March, 1882, of 5½ per cent. on the ordinary shares, and carrying forward a balance of about £1,000. The next meeting of this company will take place at the Cannon-street Hotel on the 13th July, at 2 p.m. The report will be found in another column.

THE ELECTRICIAN.

TO CORRESPONDENTS.

All communications to be addressed to 396, Strand, London, W.C.

All letters intended for insertion in THE ELECTRICIAN, *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

SUBSCRIPTIONS.

THE ELECTRICIAN *can be had, by order, from any newsagent in town or country, at the various railway stations; or it can, if preferred, be supplied direct from the office, on the following terms (paid in advance):—*

Quarterly .... 4s. 10d.
Half-yearly .... 9s. 9d.
Yearly .... 19s. 6d.

P.O. Orders to be made payable to James Gray, at West Strand Post Office.

NOTICE.

VOL. VIII. of THE ELECTRICIAN,
STRONGLY BOUND, WITH COPIOUS INDEX,
NOW READY.

Price 10s. 6d.

CASES FOR BINDING ALSO READY. Price 2s.
Order of any Bookseller or Stationer.

THE INLAND TELEGRAPH SERVICE.

The promulgation of a revised classification for the maintenance, or engineering, branch of the Post Office Telegraph Service, now officially announced, is, we believe, the last word of the Treasury in answer to the demands made upon it some two years ago. The members of the engineering branch did not to any considerable extent join in the agitation for re-classification, and as a reward for their moderation they have been served last. Our present information, however, goes to show that, on the whole, the claims of the technical department, though longest delayed, have been fairly considered, and with results that are generally satisfactory. An exception in respect to linemen, who, we understand, get nothing, is to be regretted; but is perhaps intelligible on the ground of their being unskilled workmen whose places can always be filled on the spot without difficulty. This, at least, is the only explanation we can suggest for their being left out in the cold. Whether the workmen themselves will consider it a sufficient reason for continued abstentation from combination and agitation on their own account is another matter. The rest appear to be satisfied, and, for the present at least, all seems quiet in that quarter.

As much cannot be said apparently for the general body of the working staff. In our last issue we gave an account of a meeting held in London on the previous Sunday, which showed that a twelvemonth's trial of the scheme devised for their benefit has failed to give satisfaction to the telegraph clerks. "The Annual Conference of the Postal Telegraph Clerks' Association"—which was the designation of the meeting to which we refer—is, perhaps, more formidable in sound than in fact; but, taken in connection with a number of meetings of a similar kind, and with letters in the newspapers—which have hardly ceased their importunities since the scheme was first issued—this meeting in the metropolis cannot be lightly passed over. We sincerely hope that a like fate does not await the classification for the engineering staff; for if such were the case, after its operation has been looked into more carefully, there will be little chance of peace for the service as a whole. A combination among the aggrieved of both sections would bring about as threatening a state of things as prevailed in 1880. Undoubtedly the authorities managed adroitly enough to break up the combination of that year by rewarding secession from its ranks, and withholding reward from the refractory. This is a policy which averts serious danger; but, unhappily, it also serves to intensify discontent. It diminishes the area, but increases the bitterness of the conflict. No possible classification could have given satisfaction to all parties; but any classification that leaves a considerable section of the *employés* in the ranks of the disaffected, as that of 1881 appears to have done, must be defective somewhere, either in principle or application.

As nothing has latterly been said about promotions being arbitrarily withheld where they have been officially sanctioned, we may assume that the scheme as framed for the telegraph operators has at length been applied all round, and that the men know exactly what they can claim and what they may look forward to. Classification is what the Telegraph Clerks' Association appear to quarrel with. It is true that the first resolution expresses strong dissatisfaction "at the unjust and partial manner" in which the scheme has been applied; but as the scheme itself must have left an opening for this form of application—supposing it to have been practised—the scheme, and not the administration, bears all the blame. The resolution further protests against "the inadequacy of the scheme of revision," and concludes by expressing its "indignation that while the scheme ostensibly confers benefits, however small, those benefits are to a large extent diminished by the system of classification which is still retained." A sentence, beginning with indignation and ending with classification which is still retained, besides being flat, is bewildering. One would have expected the indignation to be reserved for those local authorities who are implicitly accused of applying the scheme in a partial manner; but, unless we are to take it that the epithets grow stronger as the offences get milder, we are driven to the conclusion that partiality and unfairness are as nothing compared with the system of classification which is still retained. Here again we are at a loss to know whether it is the system or the continuance of it that arouses indignation. If they object to any sort of classification these delegates should say so; nay, they should have said so before the old classification was succeeded by an amended one of the same order. We have on former occasions pointed out the objections to classification as it prevails in the Civil Service—a system which is, moreover, opposed to all the traditions and usages of the old telegraph companies. Those objections are many and sound, but they are not likely to be heeded in a service where classification is the basis of the entire organisation. Nor do we think that the new race of telegraph clerks would be benefited by the abolition of

Digitized by Google

classification in deference to their prejudice. When fixity of location has become the rule, and not, as in former times, the exception, classification of some kind is indispensable in the interests of the clerks themselves, who would otherwise very speedily experience the pinch of fixity of wages. No sensible man, however, quarrels with a classification which classifies him comfortably; and we may, therefore, not uncharitably assume that what the conference are indignant about is that they have fared badly under the classification as it is, not that any kind of classification is "still retained."

The next resolution is of more mysterious import. The conference are of opinion that an inquiry by a Select Committee of the House of Commons into the administration of the Telegraph Department is necessary in the best interests of the service. "In the best interests of the service" is, perhaps, a mere rhetorical flourish, pardonable in the circumstances of a conference claiming to pass resolutions "on behalf and at the desire of the postal telegraph clerks of the United Kingdom;" but, while declining to endorse the declaration that such an inquiry is necessary, we are certainly disposed to think that it might be useful. For one thing we should learn exactly what the Association really desire. Their resolutions are, if we may be pardoned for saying so, exceedingly mixed. If there are specific local wrongs, surely they can be remedied by energetic local action better than by innuendoes at a London tavern; and if the classification works out badly in practice, its radical errors can be pointed out without accusing it of ostensibly conferring benefits which it knows to be illusory. We do occasionally hear of parliamentary committees at work, though we have almost forgotten what parliamentary Acts are like; and an investigation before such a body would probably settle this vexatious agitation once for all. If the Department wants to do justice, as no doubt it does, it has nothing to fear; and if the clerks, or the Association on their behalf, can draw up a substantial case for such a committee, we should be inclined to take them at their word. Facts, however, that will bear rigorous investigation would have to be adduced on an occasion of that sort; and much as we sympathise with the individual cases of hardship which have, no doubt, occurred in dealing with the claims of so numerous a body, we have as yet seen no evidence deserving of the name to warrant the sweeping condemnations which find their way, unsifted and unauthenticated, into newspaper columns, or in the cut-and-dried resolutions passed at conference meetings—none, at least, which would pass the ordeal of a cross-examination at Westminster. The third and concluding resolution had reference to the grievances of pre-transfer clerks, but we must reserve our remarks upon this subject for another occasion.

SUBMARINE CABLES.

The accidents which occurred last summer to various cables radiating from England to the Continent, the knowledge that some of these accidents were caused by wilfulness, and others by gross carlessness, led the Cable Companies to communicate with the Board of Trade on the subject. Previously to this many complaints had been made as to the suitability of lights used by cable ships, these being similar to distress lights, and frequently leading to confusion. The representations made by the companies have resulted in certain improvements, which will, no doubt, be appreciated. The signals have already been revised, and it will be seen from a communication, given elsewhere, from the Board of Trade to Mr. J. Pender, M.P., a definite statement is made that there is a legal remedy for the Cable Companies in case of wilful damage. It is, of course, necessary that other governments as well as the English should concur in assisting to maintain the inviolability of cables from wilful damage, and although the negotiations are not yet concluded, as will be seen from the last clause of the letter previously mentioned, we believe that the governments communicated with are in practical agreement on the question.

CORRESPONDENCE.

WHAT IS ELECTRICITY?

Temperature.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The object of my present paper is to show the mode in which the force of the sun is productive of change of temperature, and effects the expansion of bodies under low as well as high temperatures.

1. It is well known that the heat of the sun does not really reach the earth, for even in the tropics the snow mountains—which are points on the earth's surface most exposed to the sun's influence—are, of course, many degrees lower in temperature than the valleys beneath; and, again, observations made during balloon ascents prove that temperature diminishes as altitude increases.

2. I have stated that the fact is well known that the heat of the sun is not transmitted as heat to the earth; but yet a degree of obscurity on this point appears to exist, which, in one way or another, ought to be removed, for a very able compiler of sun facts—Dr. Young—states that "all waves of solar radiation are carriers of energy, and, when intercepted, do work, producing heat, or vision, or chemical action, according to circumstances." But he immediately adds, "If the amount of solar light is enormous, as compared with terrestrial standards, the same thing is still more true of solar heat, which admits of somewhat more accurate measurement, since we are no longer dependent on a unit so unsatisfactory as the 'candle-power,' and can substitute thermometers and balances for the human eye."

3. The first statement appears to regard rise of temperature on the earth's surface as due to the energy of the sun; the latter, as I interpret the words to mean, conveys that we are able to measure the heat which the sun transmits as heat to the earth. But, whether my construction of the passage be right or wrong, it is evident that no ambiguity should exist upon this very important point.

4. In my letter upon the mode of transmission of the imponderables, and more especially on the propagation of light, I pointed out that the force which is given out as magnetic force over every portion of the earth's surface takes a helical direction in accordance with the laws of magnetism, and that the lines of force which reach the earth from the sun are disposed in like manner. I also showed by the laws of motion that the helices increase in a given space with the resistance or density of the matter.

5. In my letter on universal gravitation I have shown that vortices of force are generated by the motion of the earth, in common with the motion of the celestial bodies, owing to their motion imparting a like motion to the medium in which they rotate.

6. We may in a measure judge of the effects of this motion of the celestial bodies upon the matter surrounding them more immediately, as well as the matter in interplanetary space, by rotating a well weighted orange in a large glass jar of water. The motion of the orange will impart motion to the whole of the water, and this motion will be continued in spite of the friction of the sides of the jar, &c., long after the orange has ceased to move. Now, when we consider the effects of such motion of the orange upon the matter in which it is immersed, and compare it with the motion of the mass of one of the celestial bodies, and bear in mind the high rate

Digitized by Google

of motion of the latter, its incessant character, and the indestructibility of the momenta or waves, and yet further, the little resistance the attenuating medium offers to the transmission of these waves of motion, we can form some slight estimate of the degree and character of the motions which the celestial bodies propagate to the medium in which they move, and to each other.

7. It is a well known fact that the rays of the sun are productive of increase of temperature in proportion as they are more or less direct, and that expansion occurs in bodies under heat, and in some, probably in all, under cold also.

8. The cause of this expansion under heat is attributed to the property heat possesses as a force of repulsion; but why increase of temperature should act in such manner has not that I am aware of been shown; much less has it been determined why bodies expand under the influence of cold.

9. I now hope to prove conclusively why the direct rays of the sun's helical force cause density to be diminished and temperature to be increased; why density is increased and temperature reduced under the oblique rays of the sun as the poles of the earth are approached; and why bodies expand again at a low temperature.

10. First, with regard to the production of increase of temperature, and the expansion of matter under the direct application of the force of the sun.

The mechanical effects of the force of the sun and the force of the earth in the elevation of temperature and the expansion of the matter acted upon may be readily illustrated in the following simple but effective manner.

Take eight or ten pieces of stout cord, such as is used for window blinds, about five inches in length. Lay them side by side, and then tie some fine twine tightly round the ends; they will thus form one cord, the strands of which are loose. A helical character may be imparted by twisting one end to the right and the other to the left. The strands of the cord being expressive of the force or motion imparted by the two hands, and the twisting being in opposite directions, all the strands will be right, or all of them left-handed helices, in accordance with the twist given.

11. Let one half of these strands represent the force of the sun, and the other half the force of reaction absolutely developed by the motion of the earth. By continuing the twisting motion, and at the same time gradually pushing the bands more closely together the cords will project outwards on all sides equally, and exhibit a tendency to be arranged in a spheroidal manner.

12. To make application of this principle to the elevation of temperature and the expansion of bodies exposed on the surface of the earth to the full influence of the sun's force, we have to consider closely the direction in which the sun's force is applied; the direction of the force of reaction as described above; and the law which determines that temperature is raised in inverse proportion to the conducting power of the matter acted upon—a law which has special significance with reference to the heat generated in conductors of electrical currents. Having done this we are bound, as it appears to me, to recognise the fact that molecular motion and lateral extension of the helical lines of force must be in exact proportion, other things being equal, to the resistance matter offers to the passage of the two forces; for, in proportion as the force is impressed with a velocity which exceeds the conducting power of the mass, it is bound to display itself in driving the atoms asunder laterally.

13. We thus ascertain that the force which has been exerted upon matter to bind it together is simply diverted from its course; and that we really have to do with force and matter under three conditions or states, one of which is due to the action of the sun, another to the motion of the earth, and a third appears to be a natural concomitant of the gaseous, etherial, and expanded state of matter; or that condition in which matter is found when not subjected to the compressing influences of mass motion. This view is supported by our knowledge of the molecular condition of gases, which have a tendency to exist in the spheroidal state; and also of the vapourous state of water, as it exists in the form of steam, dew, or fog.

14. It further becomes a question whether this attenuated condition of matter is not also induced as a consequence of the molecules being subjected in a finely divided state to the influence of the two first-named forces in a degree which they—the molecules—have not capacity to retain, and which, consequently, displays its power upon them precisely in the same manner as it does upon the larger masses. And as the elevation of temperature, other things being equal, depends upon the density of the matter, we are naturally led to the conclusion that, in the finely-divided state in which matter exists in interplanetary space, there may be a very low temperature, owing to the same principle prevailing upon these infinitesimal particles as evokes low temperature at the poles of the earth.

15. Unquestionably, the more we investigate this universal principle of action, the more we realise that every condition of matter of which we can take cognisance is resolvable into the conversion of atoms into molecules, and molecules into masses, under the influence of forces acting upon helical lines from without; and, further, that by simply reversing the direction of the force it may be made to disperse masses and molecules, and reconvert them into atoms, the two processes being well illustrated by the iron filings under the influence of magnetic attraction and repulsion.

16. We further perceive in this expansion of one portion of the earth's surface, combined with the condensation of the opposite side and the condition of the poles, a third and not unimportant element in the earth's rotation; for balance of power or equilibrium must be affected thereby.

17. (Secondly). We have next to consider the operation of this force at the poles of the earth, and to realise the full extent of the influence we must bear in mind the fact that the force of the sun is constantly being impressed over the whole of the sunward surface of the earth; and that all this force, which may be expressed by hundreds of quadrillions of tons, has to be projected again as indestructible force at the magnetic poles.

18. We have also to remember that the force of the sun passes directly over the surface of the terrestrial poles, at which points it is gathered into vortices by the immediate influence of that portion of the sun's force which, having exerted power or done work upon the mass of the earth, is then emerging. We have, therefore, force from both these sources acting upon each other in oblique lines.

19. Again, we have to deal with the influence of the force due to the motion of the earth, which, as I have already shown, forms vortices in the opposite direction; the momenta of these vortices being due to the motion of the earth are equal to the force of the sun expended upon the earth, for the motion of the earth is due to the force of the sun.

20. These latter vortices move helically from west to east, owing to the constant change in the axis of the earth's inclination, whilst those due to the sun's action move from east to west, so that here again we have the principle evolved of one helical force moving into another, and thereby causing attraction in proportion to the helices operating, and we thus find in nature a grand demonstration of the mode in which the laws of motion are evolved, and that the principle accords in every particular with the theory I advanced as to the cause of artificial magnetic phenomena, *vide The Electrician*, June 25, 1881.

21. Confining attention at first to the sun's force which acts upon the mass of the earth from the line of the ecliptic to the poles, and to the force of reaction which is due to the motion of the earth, we perceive that each force is tending to press matter towards the centre of the earth, and, further, that the pressure from both these sources must be greatest at the poles of the earth, or at those points where, by the motion of the earth, the force of the sun acting in either direction has been brought to a focus.

22. Extending our observations outside the mass of the earth we find the sun's force displaying itself in lines which pass directly over each geographical pole for six months in the year alternately and persistently, and for twelve hours out of every twenty-four hours over each magnetic pole alternately. These lines of force are, therefore, moving in the same direction as the lines of force, also of solar origin, which, after having done work upon the mass of the earth,

Digitized by Google

are emerging from the magnetic poles. Consequently, the laws governing oblique forces come into operation, and acceleration of motion and relief of pressure must be promoted thereby, and that in proportion to the degree and persistent character of the obliquity.

23. It is, therefore, evident that waves of motion must be communicated to interplanetary matter from these periods of magnetic acceleration, which occur as the opposite magnetic poles are exposed to, or removed from, the direct lines of the sun's force; and I would venture to suggest that the annual and diurnal variations of the magnetic needle, the equinoctial disturbances, and the motion of the mass in the form of an ellipse take their origin in these changes of motion.

24. The primary compressing effect of these influences of the sun is to increase density from the ecliptic in both directions towards the geographical poles, whilst from the flattening at the geographical poles pressure is suddenly relieved at those points. The secondary effect, due to the earth's motion, is to compress the earth from the poles to the centre.

25. This outline of the mode in which the force of the sun manifests its power upon the earth exactly accords with the expansion of bodies under heat as well as under cold, for we find that temperature diminishes as the rays of the sun become more oblique; and, taking the various conditions of water in illustration of the principle, we find that its density and temperature diminish in the same ratio until the temperature has been reduced to 40 degrees Fahrenheit, from which point down to 32 degrees Fahrenheit density appears to remain stationary. Sudden and violent expansion then takes place, and at the same time the liquid is converted into a solid.

26. We are, therefore, confirmed in the opinion already expressed, that the density of the mass of the earth depends upon pressure exerted from without, and that the sudden expansion of the liquid, water, whilst undergoing conversion into a solid, is absolutely due to that particular form of matter having acquired as a liquid its greatest capacity of holding force in its meshes at 32 degrees Fahrenheit, and that the force driven into it after its temperature has been reduced to 40 degrees Fahrenheit begins to operate in the opposite direction; whilst at 32 degrees Fahrenheit, under the influence of a sudden effort of an expulsive nature, the molecules are combined into a solid, the force manifesting the direction it has taken in the expulsive effort by the linear structure of the crystals, and especially giving proof of its continued presence in the solid by the change which is effected in the magnetic condition of the body, which from being a highly diamagnetic liquid has become a solid radiating magnetic force.

27. Professor Tyndall has experimentally shown that water becomes magnetic when it is converted into ice, and that the magnetic properties of ice vary at different temperatures. This is a very important fact, as evidencing the intimate relations which subsist between the material condition of a body and the power that body has of radiating magnetic force. Surely this single fact demonstrates—1st. That the same body, under different molecular conditions, gives out force with greater energy to the surrounding media, and in a direction which accords with the well-known lines of magnetic force, and, secondly, it is equally evident that a body cannot remain in the same physical condition and constantly impress force upon adjacent matter without obtaining its energy or capacity for doing work from some source external to itself. The thing would be a physical impossibility.

28. In the experimental researches of Professor Tyndall, referred to above, we have, indeed, proof given that the condensation of water has been effected by compression of its molecules by force which it has received from the surrounding media, and that when the capacity to retain force has been acquired it yields up the force in the same proportion as it has been received.

29. This principle may be illustrated by the manner in which bodies absorb water. Thus a piece of cloth will absorb and retain water in its meshes until saturation or its capacity for holding the water has taken place; then the stream of outflow will equal that of the influx, the cloth remaining saturated. The illustration may, indeed, be carried further by inclosing the cloth in a thin glass capsule, open at one side only to admit the water. By pressure from a pump we may then drive more water into the cloth, but a point will be attained when the glass envelope will be violently shattered owing to pressure from within. The cloth, however, will remain saturated, according to its capacity of holding the water, if the influx be maintained.

30. I am well aware that objection may be taken to the illustration, owing to the presence of the matter, but it is evident that were it not for the impressed force the matter under any circumstances would be quiescent. For instance, a number of billiard balls, as is well known, may be placed in a row, and a blow struck or force impressed upon one of the terminals will be transmitted through the row, but owing to stress the other terminal will be the only ball to move away, and if this were retained in its place, it would communicate its motion to the matter with which it came in contact. This principle is bound to hold good in every case of impressed force, the motion is always transmitted even if the matter with which it is associated be apparently motionless, or altogether from its tenuity invisible to our unaided senses.

31. From the statements already made, it will be perceived, first, that freedom of motion and molecular attritition are both increased, under the expansion of bodies, by force acting from within; secondly, that increased density, or condensation with reduction of temperature down to a certain point are the concomitants of pressure from without; and, thirdly, that below this temperature there is sudden expansion again owing to the capacity of matter for retaining force under great external pressure having been exceeded.

32. The principle here put forth entirely accords with the evolution of every natural phenomenon, for starting from the inter-tropical regions, we have abundant evidences of the dispersing force of the sun in the activity of molecular motion, which takes place in exact accordance, other things being equal, with the rectilinear direction in which the force of the sun is applied to the earth. This is especially marked in the propagation of light, in the evaporation of water, in the phenomena of animal and vegetable life—the radicle descending in the latter under the influence of the sun's force, or action, the plumule ascending under the force of the earth's motion, or reaction, and both formations frequently exhibiting the helical direction of the force operating. Cyclonic and other storms, the formation of dew, rain, hail, &c., are all of them evidences of the reverse principle, or the combining influence of the sun's power. Perhaps the phenomena of the water spout afford one of the most perfect methods of observing in nature the mode in which such vortices as I have described are formed under the influence of action and reaction, for in the upper inverted cone, in which helical motion is clearly discernible, sometimes of a double character, we have the matter aggregated which has been diffused in the atmosphere, and by its presence and motion imparting a like helical motion to the matter beneath; the two forces then mutually co-operate to unite the masses with which they are associated; and this having been effected, gravitation takes the matter to the earth in the manner I have described in my last letter.

32. Continuing our observations towards the poles we find molecular motion becoming gradually less marked, until at the poles, the vast fields of ice testify to the enormous force which is there operating to compress the liquid into the solid, with reduction of temperature from absence of molecular motion.

In my next letter I hope to define clearly the mode in which electrical phenomena are evolved under certain conditions of the same force.—Yours, &c.,

RICHARD C. SHETTLE, M.D.

Reading, June 23rd, 1882.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish Mr. Johnstone would keep to the point; too much time is lost in animadversions upon the ignorance of his opponents.

The question is, has Mr. J. proved that electricity is *matter?*

Digitized by Google

I have not denied that it is, but what I say is, that he has most certainly proved nothing but the existence or the non-existence of currents under certain specified circumstances. What the interpretation of *current* is, Mr. J. has not demonstrated, so it still remains a "figure of speech," better comprehended by the theory of *energy*, or Faraday's "polarisation of atoms" than that of *matter*.

The parallelism about the voice consists in this, viz., that it no more follows that *matter* has passed through Mr. J.'s jar than that *matter* has passed through the window pane. Notwithstanding the relation of cause to effect, his allusions to vacuum, &c., are quite inappropriate.

Smeaton and Sir Wm. Watson were among the first to investigate the phenomena of the Leyden jar. The latter affixed to his jar knob, by a light jointed arm, a pith ball, which rose as the jar was charged (just as Mr. J.'s flame yielded), and he noted the fact that as the jar became charged the current gradually ceased. Yet Mr. Johnstone says *his* "discovery of the fact is new in the science of electricity." I am afraid he is mistaken.

Mr. J. recognises my admission of the term *current of electricity* as a "figure of speech," but objects to my application of the "figure" when alluding to the "neutralisation of a charge." Rather inconsistent, I imagine. The same conception of a decomposed *force* admits of its recomposition.

Mr. Johnstone forgets that his is the affirmative and mine the negative side of a proposition distinctly laid down by him, and, therefore, I decline to hypothecate to gratify him.

So far we are asked to believe that "because" a current ceases to flow from a fully-charged jar, that, "therefore," "electricity is matter."

"There is no such thing," says Mr. J., again, "as magnetic repulsion." Does he want to insult the intelligence of every schoolboy who points a magnet at his pocket compass?

Does Mr. J. want us to take his dictum for it, that *matter* actually passes hundreds of miles in a second *through matter* when a telegraphic message is sent from London to New York? What, again, are we to think of duplex telegraphy? If the electrical *matter* is infinitely attenuated, each despatch must wholly invest the conductor simultaneously. If not, then the *matter must have weight;* let Mr. Johnstone devote another experiment to ascertain it per volt.

"Induction is a myth," forsooth. What about an intensity coil? If the electrical current through the *primary* is "*matter*," the secondary has received it, according to Mr. J., beyond a shadow of doubt or the least attempt at logical distortion. But, lo! the secondary current is to the primary as Boreas to a Zephyr. Whence this increment? If so much *matter* did the business in the primary, where did the rest come from in the secondary? Echo answers, "Where?"

Dealing with *forces*, we can commend to our reasoning faculties such increments as are due to *gravitation* and the like; but not with *matter*. Mr. Johnstone objects to any parallels. Let me ask him what parallel there is between the distance from his dielectric to its insulator, and the distance from one side to the other of his dielectric itself? Let him join a telegraph wire in circuit with telephones, as I have done, and the induction sounds from its neighbour are audible; but increase their distance considerably, and the sounds are no longer heard.

Is it not incredible, again, that *matter* should prefer a solid body to air as its channel of motion? Yet a current takes a copper wire, rather than the free space around it.

Finally, the phenomena of the extra spark, the return current, are consistent with such ideas as reaction of *force*, but are irreconcilable with the conception of *matter*.

We recognise forces almost everywhere, but the ultimate atom of mere solidity nowhere, except in the imagination.

Let me conclude in the words, I believe, of the great producer of that "myth induction." "We must be careful to distinguish mere assumption from fact, nor yield to the temptation, so strongly fostered by habit, of referring observed phenomena to certain views to which the mind may have been long moulded and shaped" (say since 1839).—

Yours, &c., D. HARBORD.

Redhill, 1st July, 1882.

AMPERE'S MNEMONIC RULE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following suggestion of a mnemonic rule for fixing in memory the relation between the direction of a current and the deflection it produces on a magnetic needle has been sent me by Mr. G. F. Smythe, of Greylock Institute, South Williamstown, Mass., U.S.A. It is as ingenious as novel, and, if not of as universal application as the mannikin of Ampère, is at least worthy of preservation.—Yours, &c.,

SILVANUS P. THOMPSON.

University College, Bristol.

"As a substitute for Ampère's rule, given in your 'Elementary Lessons,' page 152, I have found the following useful, as being more easily retained, though not so scientific, perhaps. If the current flow from South to North Over the needle, the north-seeking pole turns West. S-N-O-W are the initials of the important words. So I say to my classes, 'Remember *Snow*.' Of course, if one is kept in mind, the other three cases are easily recalled."

LITERATURE.

MAGNETISM AND ELECTRICITY.*

This work seems to be the first of a series called the "High School Science Series." We have always had a strong partiality for Dr. Wormell's works, not because they are perfect but because they have been written both with a thorough grasp of the subject and a sound knowledge as to the best way in which the subject should be taught. This book is no exception to the rule, as will be seen from the extracts given further on, which we believe cannot fail to be understood by the average scholar if he gives only ordinary attention.

The book is divided into two parts—the first dealing with magnetism, the second with electricity. At the end of the first part, and interspersed in the second part, are pages devoted to questions on and descriptions of experiments in the laboratory, while at the end of the book, after the index, a number of examination papers are given. The various phenomena are illustrated by experiments described in the text. It is but just that we should call attention to the manner in which some of the diagrams have been cut or printed. Take, for example, Fig. 11, p. 27, which has six letters indicating six different points. Three letters are clearly given, one is broken, and two are unrecognisable. A French publisher would have burned the block in disgust, and justly. It is annoying to have to waste time to distinguish letters or parts of diagrams. On page 102, an *s* is referred to in the text, but it will not be found in the diagram; on page 132 we have *m* in the text, M in the diagram, *n* being correct in both, and so on. This is a minor blemish, but one that, with a very little care, could be avoided.

These mistakes point to careless revision, as also does 1·20 (p. 54) for 120, and no doubt will all be corrected in the next edition.

We have often spoken and written about the symbolic nomenclature adopted by electrical writers, and have urged that some general understanding should be come to in this matter. This is not the place to enter fully into the subject, but it may be worth while suggesting that the example of chemists might with advantage be studied. The most important phenomena may then be symbolised by the first letter, and others by the first as a capital followed by a prominent letter as a small letter, *e.g.*, C = Current, Cp = Capacity, and so on. It must not be supposed that because we do not discuss the paragraphs seriatim that we agree with all that is stated. We might question whether like poles do repel, whether "diamagnetism" is a correct term or

* *Magnetism and Electricity: An Elementary Text Book for Students.* By G. R. WORMELL, D.Sc., M.A. [Thomas Murby, 32, Bouverie-street.]

Digitized by Google

not; but we recognise the necessity in a work of this kind of an author avoiding as much as possible controversial points and giving the student the generally-accepted views. That the reader may judge for himself of the author's method we give one or two extracts:—

MAGNETIZATION IS A MOLECULAR CHANGE.—The force by which the particles of a solid body are bound together is called cohesion. It is found, as might be expected, that the kind of iron which retains its magnetism best is that in which the force of cohesion is greatest. Moreover, whatever affects the cohesion of the particles in iron affects its magnetism. Heat lessens the cohesion and diminishes the magnetism of a steel magnet. Molecular attraction may be overcome, and magnetism destroyed, by sudden concussion. The twisting of a magnetised rod diminishes its magnetism. An iron or steel bar, which is slightly curved by its own weight, becomes straight on being magnetised.

When a bar is magnetised it stretches longitudinally and contracts axially. Hence there is greater density, so to speak, in the latter direction. This is manifested by the change that takes place in the thermal conductivity of the bar. If a thin plate of soft unmagnetised iron be covered with wax, and heated at its centre, the heat is conducted equally in all directions, so that the form of the melted wax is circular. If, however, the plate be placed between the poles of an electro-magnet, then the melted wax is ellipitical in form, being longer in the direction at right angles to the line joining the magnetic poles, so that the conductivity is greatest in this direction.

TANGENT GALVANOMETER AND VOLTAMETER COMPARED.—It follows that if a tangent galvanometer and a voltameter be included in the same circuit, the volume of hydrogen, at a constant pressure and temperature, produced in a given time will be proportional to the tangent of the deviation. For instance, the current produced by E M F of 1 volt through a resistance of 1 Ohm decomposes ·00146 grains of water in a second, and liberates ·0113 cubic inches of mixed gas per second, at temp. 32 deg. F. and under the normal pressure; hence the measure of a current decomposing x. grains of water a second is $x \div \cdot 00146$ volts; a current that liberates x. cubic inches of hydrogen per second is $x \div (\frac{2}{3}$ of $\cdot 0113)$ volts. It has been pointed out that the indications of different tangent galvanometers are not readily compared with one another. With a given current the deflection depends on the diameter of the rings and the force of the earth's magnetism, which varies in different localities. By comparison with the voltameter the indications of all such galvanometers may be reduced to a common standard.

It should be remarked, in connection with the electrolysis of water and other compounds, that the amount of chemical action in the voltameter is always equivalent to that in each cell of the battery; and if a number of voltameters be interposed in the circuit, the action in each will be chemically equivalent to that in the battery.

The chemical action that takes place in a cell containing copper, zinc, and acidulated water is as follows:—The water is decomposed, bubbles of hydrogen forming on the inner surface of the copper plate, and the oxygen combining with the zinc to form oxide of zinc. If we write Cu for copper, Zn for zinc, and H_2O for water, this action may be represented thus:—

$$\begin{array}{ll} \text{I.} & Cu \quad H_2O \; OH_2 \; OH_2 \quad Zn \\ \text{II.} & Cu \quad H_2O \; H_2O \; H_2O \quad Zn \\ \text{III.} & Cu + H_2 \quad OH_2 \; OH_2 \; OZn \\ \text{IV.} & Cu \quad H_2O \quad H_2O \quad Zn \end{array}$$

1. At first the molecules of water are supposed to rest in the vessel with the atoms of hydrogen pointing in different directions.

2. After the *poles* (as the zinc and copper plates are called) have been introduced into the liquid, the molecules of water become *polarized*, that is, they turn so that in each molecule the hydrogen is nearer to the copper plate, and the oxygen nearer to the zinc, as in the second row of the above formulæ.

3. When the circuit is completed, and the current flows, the hydrogen of the molecule of water nearest the copper plate is separated from the oxygen, and appears as bubbles on the plate. The oxygen of this molecule combines with the hydrogen of the next molecule, forming a molecule of water, and setting free another atom of oxygen. This combines with the hydrogen of the next molecule, and so on, until the atom of oxygen nearest the zinc plate is set free, and combines with the zinc to form oxide of zinc. The molecules of water are then left in the position represented by the third row of the figure.

4. As the current continues, the molecules again set themselves in the position described in II. and the process is repeated."

A feature in this little work is that the student is gradually led to see how the principles of the science have been applied in apparatus for electric light purposes, telegraphy, telephony, &c., while on p. 229 is the following paragraph devoted to Unsolved Questions.

UNSOLVED QUESTIONS.—Our knowledge of what electricity *will do* is still daily advancing, and we are justified in predicting that it will be of immense service in the future; but when we ask what electricity *is*, we have to confess that very little is known about it. In the case of sound or light, we know what it is that is transmitted, and also the velocity of the transmission and the direction it takes; but we have no similar knowledge with regard to electricity: we neither know what it is nor the process whereby it is transmitted. We have no certain clue to the actual direction of the transmission. We know how to produce electricity, or electrical action, and how to transmit it by means of wires to a distance; we know, also, that there is a dinymmetry at the two ends, or terminals, of a battery or machine, implying a directional character either in that which is transmitted or in the mode of its transmission, so that we cannot dismiss from our minds the notion of direction, and we have assumed it for convenience of speech and description. We have, however, no experimental facts that will decide whether the motion or "current" of electricity is to be considered as starting from one terminal and arriving at the other, or as starting from the second and arriving at the first; or, indeed, whether the motion may not be in some sense double, in both directions at once.

THE APPLICATION OF GAS TO THE LIGHTING OF OPEN SPACES.*

[Although the title of this paper mentions "Gas" only, it will be found that Electricity is a prominent feature in the body of the paper.—ED. *E.*]

BY WILLIAM T. SUGG.

It has very frequently been asserted by men of high position in the world of commerce, as well as by eminent scientific men, that the electric light is more suitable than gaslight for illuminating large areas. It is to be presumed that this *dictum* has been received as something absolutely true by a large section of the public. Chairmen of gas companies, in their half-yearly speeches, have even said pretty much the same thing, and have seemed almost to believe that really gas has no chance against the electric light, at least for large open spaces. In parenthesis let me say that it is also true that lately Professor Crookes and other learned authorities have told us that gas is neither so cheap nor so good as electricity for small spaces.

The House of Commons were moved by the statements everywhere made actually to order a trial of the most public-favoured specimen of the electric light for the purpose of lighting the Parliament Chamber, instead of gas, which was declared by some to be obsolete, impure, and deletereous to the atmosphere. The electric light, however, did not succeed, notwithstanding the permission given to the Brush Company, even to alter the ceiling by lowering a number of square glass lamps of considerable length down into the interior of the chamber. Gas was found to be superior to the Brush electric light for lighting the House of Commons, which is a large interior space. And here it is

* A Paper read at the late meeting of the Gas Institute.

Digitized by Google

necessary to say that at no time, either before or after the experiment, could the heat or the products of combustion from the gas mix with the air supplied to the House; for two reasons—first, the pure air is supplied from below the floor, rising continually, and the vitiated air is carried off through the ceiling; secondly, because the gas-burners are fixed above the ceiling, which is of glass, and help to carry off heated air from the interior of the roof through their own ventilators, each one being separately ventilated.

Popular prejudice, however, does not reason; and there are still found men in high positions who repeat the same fallacies. Only lately the Commissioners of Sewers of the City of London invited tenders for lighting several of the streets of the City by electricity, and it was declared by one of their number (Mr. Innes) that the contracts they had before them showed that the electric lighting involved an expenditure of more than five or six times the amount then being paid for lighting by gas. The same body refused to pay three times the cost of the old lighting by gas for a new and superior system, which gives nearly six times more light than the old; and yet this new system of lighting streets by gas has often been declared by the public Press and by the general public to be superior to the electric light. Still more recently they have averred, as a reason for not adopting gas for the better lighting of the streets, that the Brush Electric Light Company were supplying their electric lights under contract for the same price as the Commission paid to the Gaslight and Coke Company for the 5ft. per hour lamps previously used. Yet it is a remarkable fact that the Siemens electric arc lights (which are produced certainly at as cheap a rate as any electric light now before the public) could not be supplied at a less cost than five or six times the price of the original gas lighting; and it is a still more remarkable fact that the Brush Electric Light Company did not offer to supply the whole of the City on the same terms as those under which they are now supplying Ludgate Hill and Cheapside, considering that it has been so frequently stated by their advocates that they can supply light for streets and open spaces at the same rate as gas.

It is true that it is now asserted that if they were allowed to light shops off the same wire as those supplying the public lamps they could do the electric lighting more cheaply; but they do not say how much more, neither does it appear that public and private lighting on the same wire could be managed with either safety or profit. But notwithstanding the figures of the tenders received and this positive commercial assurance that no one is willing to supply at a lower rate than five or six times the cost of gas, yet it does not seem to occur to the Commissioners that they might try gas for the purposes they require until electricity is proved to be able to do the work better and more cheaply. The reason why they do not try gas can, I believe, only be because they really think the electric light is superior to gas upon all points for this purpose.

From the first, since I saw the electric light in Paris, I have never had but one opinion on this subject, and that is, that whatever may be the proper use of the electric light—either of the arc form or incandescent form—neither of them is so suitable for lighting large space, either interior or exterior, as gas. I quite feel that, coming from me, this sounds very much like "There is nothing like leather;" but my opinion is founded on careful observations of electric lights in use, joined to a study of the system on which they are worked, and I think I can show a good foundation for my assertion of the superiority of gas.

First, as I stated in my letter to *The Times*, published October 11th, 1878, the electric light is deficient in volume. What I mean by this I will illustrate in the following manner:—It has long been customary—previously to the introduction of gas and even since—to light large spaces where such work as the unloading of barges on rivers, the loading and unloading of heavy goods, and general rough outdoor work is performed, by means of braziers, or, as they are generally called, "devils." These braziers are usually from 12in. to 15in. high, and about 10in. or 12in. broad, and when the coal or coke with which they are filled is in a state of low incandescence—viz., orange red—they diffuse a large volume of light, which covers a surprisingly wide space. The shadows of projecting objects on the ground are very slight, and for this reason this kind of illumination is often thought superior to other systems of lighting, more especially for work done on the water. I believe that one of these braziers, of large dimensions, used as a lighthouse light, is said by mariners to be more useful in very hazy weather than the most improved form of lighthouse lamp. I think, however, that this is not correct, because the volume of light, through extremely great, is of too low intensity to enable it to penetrate through even a slight mist so well as the light from a Wigham gas burner such as is used at the Howth Bailey light, off the coast of Ireland, or the improved lamp now in use by the Trinity Board, and invented by Mr. J. N. Douglass, their engineer. Professor Tyndall has declared the Howth Bailey gas light to be superior to the electric light for foggy weather. But the amount of light developed by an ordinary brazier such as I have described may be taken as generally not less than 600 to 1,000 candles, according to the degree of incandescence.

Now the very opposite to this light of low intensity and great volume is the electric light. The brazier has a radiant illuminating surface of about 500 square inches, one half of which is fully available in any direction. An electric light of 1,000 candle-power has only a total illuminating surface of about 12 square tenths of an inch, only 6 of which are fully available in any direction. The comparison of radiant illuminating surface is therefore as 50,000 : 6; so the brazier possesses more than 8,000 times more radiant illuminating surface than the electric light. This latter, is therefore, a light of high intensity, but of low volume. In the Dover lighthouses the electric lights are of about 7,000 candles measured in the photometer, and when placed in their admirably arranged Fresnel dioptric lanterns, the small but very intense point of light is developed out into a large surface of light of much lower intensity but greater volume, and they have a radiant illuminating surface of about 36 square feet. At 20 miles distance on a clear night the lights appear to be about the size of one's hand, or sometimes even larger than this. Now it is evident that if the lanterns were taken off, and the naked light only shown, at a comparatively short distance from the shore, the apparent size of the light would not be larger than a pin's head, although it would still possess in itself the full measured or nominal light of 7,000 candles. This light would, however, be useless to cover the space required, or to enable it to be distinctly seen by the naked eye at a very few miles from the shore. It is even probable that the light of a candle or at least a small lamp would, at a short distance, be more effective than this powerfully intense electric light. It is, therefore, clear that a light suitable for large spaces, or for lighthouses, must possess not only a certain intensity, but also a certain volume corresponding to its intensity.

To bring this point more closely home, I propose to instance the electric light in the City and on the Thames Embankment. It has been stated in the public journals that the Jablochkoff lights on the Thames Embankment are equal to 300 or more candles, and that the Brush electric lights in the City are equal to 2,000 candles. I am not disposed to say that they would not realise something like these figures if taken out of their lanterns at their best state of burning and placed at a suitable angle in a short photometer. But I have found that when they are tested in their places as they are used in these lanterns or globes on the tops of lamp-columns 11, 13, 15, or 16ft. high, they do not actually realise these illuminating powers.

The following details of experiments made on two very clear nights just lately will give an idea of the amount of effective light which really reaches the ground. The standard of light I have used for comparison is a Keates lamp, burning spermaceti oil, provided with a Methven slit placed across the flame of the burner, instead of vertically as in the Methven standard of light. The slit is of such size as to allow a portion of the whole light of the lamp equal to two candles to pass through it. This standard light, which I find is constant, is enclosed in a dark chamber properly ventilated; the front part of the chamber communicating by means of a

Digitized by Google

square wooden tube with one side of the comparison disc. This disc is shaped like the letter A, and covered on both sides with white paper. On each side of the disc is pasted a cutting from a newspaper, one half the reading being on one side of the disc, and the other half on the other. The two sides are separated by means of a partition, which is carried up some distance above the discs. One side—that nearest the lamp—is covered so that no other light but that of the lamp can fall upon it; the other side is left open to receive the full light from the electric or other light to be examined. A mirror properly placed enables the observer to see both sides of the disc at once, and thus to judge of the relative amount of light falling on each. The standard degree of light I have adopted is, therefore, equal to that which will fall on a white surface from the rays of two candles placed at a distance of 3ft. from that surface. The photometer as thus used is on the Church and Mann principle, as you will perceive, but it is also arranged on the King principle, and may thus be used to measure the amount of light falling in any part of a roadway at a distance of 3ft. from the ground.

On the 5th of the present month, on a very fine, clear evening, I found that at 11:10 p.m. one of the Jablochkoff lamps (No. 4 on the list) on the Thames Embankment gave a light equal to two candles at 3ft. from the disc at a distance of 18ft. 8in. in a horizontal line. The height of the post above the level of the disc being 13ft., the angle of the ray was therefore 35½ degrees. This being so, a gas-lamp of the nominal power of 114·4 candles would, according to calculation, give a like result. As a matter of fact, however, a gas-lamp of the nominal power of 60 candles, consuming 25 cubic feet of gas per hour, which has, with a great many others of the same kind, been burning in the public streets for many months past, gave on the 9th of this month (measured by the same standard) a light equal to 125·3 candles. The distance from the post was 22ft. in a horizontal line, and the light was 9ft. above the disc of the photometer; the angle of the ray was therefore 23 degrees.

It is necessary to mention here, in order that you may understand clearly the bearing of the observation as to angles, that in a published report which I have before me, dated May 24, 1882, Professor Ayrton and Mr. John Perry say that "with all electric lights the intensity of the illumination is different for different angles in the same vertical plane," and as the summary of the results of their observations at different angles of inclination they give the following:—

Horizontal	1129	Candles per horse-power electrically given to the lamp.
17 degrees	2637	
34 degrees	3042	

The electric light, therefore, in this instance appears to have the least angle. I think you will perceive from these facts that, if the cost of the electric light is a slippery subject to get hold of, the estimation of their illuminating power is enough to puzzle the most experienced photometrists.

At the refuge near De Keyser's Hotel at Blackfriars, I found on the same night that the Brush electric light there produced the standard light of 2 candles on the disc at a distance of 47ft. 6in. from the post in a horizontal line. The height of the post was 17ft. above the photometer disc; the angle of ray was, therefore, 20 degrees. Consequently, according to calculation, a gas burner of the nominal candle power of 557 candles would have produced the same result. As a matter of fact, on the 9th of this month, at 10:35 p.m., a gas lamp which has been burning in the public streets for many months gave (measured by the same instrument) a light equal to 501·4 candles, with a consumption of 90 cubic feet of gas per hour, at a distance of 44ft. 11in. from the post in a horizontal line. The height of the lamp above the disc was 15ft. 4in.; the angle of the ray was 19 degrees. In this instance the Brush light had slightly the best angle.

In both cases the gas lamp gave a constant light, and the electric light did not. The gas lamp gave its light the same in all directions round the post. The electric lamp in the latter case did not appear to do so, the results being—Down Bride-lane, 582 candles; on pavement towards bridge, at right angles with Bride-lane, 320·8 candles; across road in direct line with Bride-lane, 267·4 candles—total, 1170·2 candles. Average of the three observations, 390·2 candles.

Nearly in front of *The Times* office, in Queen Victoria-street, is a lamp on the Lontin system, which produced the standard light on the disc, at a distance of 80ft. 6in. from the post on a horizontal line. This is the most powerful light I have yet tested. To produce the same amount of light by gas would require a lamp of 1466 candle-power. Calculating from the results given in respect of the gas lamp before mentioned, a similar lamp of larger dimensions, and consuming about 280 cubic feet of gas per hour, would equal this light.

Those of you who have seen the electric lamps and some of the larger gas-lamps in use in all parts of the country, the nominal illuminating power of which does not exceed 300 or 400 candles, must have remarked that these nominally much more powerful electric lights do not light the ground better than those gas lamps of smaller nominal value. It is a remarkable fact that although at the Electrical Exhibition at the Crystal Palace the electric lights in that part of the Nave where the Kings' and Queens' screen is, numbered many thousands of candles, it was not possible from the Centre Transept to tell the time by the large clock at the south end of the Palace, which is a great deal more than 20ft. in diameter and figures about 6ft. in length. Yet I need not tell you that if that part of the Palace had been lighted by gas to a tithe of the nominal number of candles which the electric light was said to represent, it would have been a very easy matter to have read the time on a much smaller dial.

You will naturally expect that I should be able to give some reason for this curious fact. This reason is another of my arguments why the electric light is not as suitable as gas for lighting large spaces. The electric light is composed largely of highly refrangible rays which move at a very high rate of velocity. To illustrate this, let us refer for a moment to the brazier. There we have a great number of heat-rays which are the least refrangible, and which are generally supposed to be invisible to our organs of vision because of the comparatively low rate of speed at which they move. But this heat-ray, as pointed out by Professor Tyndall, is an enormous mountain amongst the other rays of the solar spectrum; and between this heat-ray and that part of the solar spectrum approaching to yellow there are a number of dark red, red, bright red, and orange rays, of low refrangibility and slow movement, which are useful to us when they are not interfered with by the more rapidly moving and more highly refrangible rays which irritate the optic nerve most violently, and render it as it were insensitive to the rays of low intensity. Captain Abney, of South Kensington, who has done more than, perhaps, any man living to elucidate the theory of photography, has shown us that even this red ray can be photographed, and thus that it probably must have a sensible effect on the human eye, more useful for the purposes of vision than has been before supposed. Now the electric light, in comparison with the brazier, possesses few heat rays, but it has an enormous quantity of rays which belong to the other end of the solar spectrum, notably the other invisible ray which is the antithesis of the heat ray—I mean the actinic or chemical ray. Professor Tyndall tells us that to produce the extreme violet rays the retina of the eye is struck 789 millions of times in a single second, and that at this point the retina ceases to be useful as an organ of vision. This ray is, however, the most useful to photographers, but does not appear at all useful in artificial lighting. On the contrary, nature provides us in summer evenings with a light which is good and strong enough for working indoors as well as out, and which, after the glare of full day, is most acceptable to the sight. This light is pure and very slightly yellow or rosy from the last beams of the setting sun, but is almost devoid of the actinic or violet rays, although it possesses the pale green ray and all the others from that towards the red. Therefore it is grateful to the sight, and is powerful to illuminate us; in fact, it possesses volume and sufficient intensity without the violently refrangible and high-velocity rays which require the strong golden beams of the sun to connect and tone down their effect, and prevent them from being in-

Digitized by Google

jurious to the human eye. This evening light is, in my opinion, what we require to replace the light of day after the sun has set. But this we most decidedly do not get from electricity in the arc form, as it is now used for lighting large interior or exterior spaces. But we can obtain such a light from gas, as I shall be able to show a little further on. Lastly, the highly refrangible rays are scattered and diverted from their course by molecules of water, and do not reach the point to which it is the intention they should be directed, even in the ordinary moist state of the atmosphere on a fine evening.

Here it is necessary to mention another fact for which we are indebted to the scientific research of Professor Tyndall—viz., that a ray of light is absolutely invisible unless it strikes upon something which may reflect it. Now, bearing this fact in mind, and remembering also that the heat and red rays, in passing through a globe of water, go nearly straight through, all the others—the orange, yellow, green, blue, and violet—being more and more bent out of their course in the order in which I have mentioned them, till in this last visible ray, and still more in the actinic ray, they reach their highest degree of refrangibility, it is clear that a light which is largely composed of these rays cannot be so serviceable for artificially illuminating a space, whether interior or exterior, as one which possesses the most rays of a lower refrangibility combined with a sufficient volume of those rays which give intensity to the light. This is the combination which we have readily available in gaslight.

It has been and will be argued that gas can never represent that mellow evening light which I have spoken of. On this point I have to cite a most interesting experiment which has only been tried within the last few days. I have spoken of the lighting of the House of Commons, and mentioned the failure to give equal satisfaction to that experienced with gas lighting which resulted from the trial of the electric light proposed to be employed instead of gas. From what I have stated as to the peculiarities of the arc electric light, you will, I think, be able to see why it could not be so successful as gas.

It has been urged that the colour of the gas light is not like that of day; it is yellow and smoky. In the House of Commons it is not easy to show whether it is or is not like the daylight, because the gaslight does not come from the same point as the daylight, and therefore the change of position tells us when gas is lighting the House. But in the new Reading Town Hall, which was opened on the 31st of May last, the architect has arranged a glass cove round the hall under the ceiling line. The daylight enters the hall first through skylights on the external roof, and then descends through the glass cove. Behind the glass cove, at a short distance from it, are placed the gaslights, each of 100 candle-power, and each provided with a ventilating shaft to carry off the products of combustion. Thus the daylight and the gaslight enter the hall from the same points; the consequence being that the following experiment as to the relative colour of gaslight by daylight could be, and was tried on the opening day:—A grand concert commenced in the hall at half-past seven, or at the time when the area was well lighted by the evening light I have spoken of, so that any small print could easily be read in any part. The last beams of the setting sun fell on the skylights of the roof, producing a fine mellow, soft, white light. The gas was then turned on to its full power, 9,000 candles for the entire hall (62ft. 6in. by 98ft. 0in.). No perceptible difference could be perceived in the light from that time till the concert came to an end at nearly eleven o'clock. The daylight gradually went, and the gaslight imperceptibly took its place; and it was remarked by every one that the change from daylight to gaslight had not been remarked. One of the public journals of Reading mentions this fact. So much did the gaslight resemble daylight that some of the audience found that it was dark when they came out of the hall between the parts, having imagined they had been sitting in daylight all the time. It is remarkable that when the daylight was lighting the hall and the gaslights were turned full on, they did not appear to alter the colour or the illuminating power in any way. But as the daylight disappeared they took up the lighting. Like the House of Commons, this hall cannot be in the least affected by the heat or products of combustion from the burning gas.

This, then, I say fulfils all the conditions of artificial lighting as to colour of light, softness of light, and volume, with perfect steadiness and control, and absence of highly refrangible and chemical rays, and with no products of combustion to vitiate or heat the atmosphere. Is not this, I ask, a suitable light for any of those museums or libraries of which we have heard so much? And does any system of electric light fulfil any of these conditions so well as gas?

As to open spaces, when the products can escape into the air, the conditions of lighting, however difficult to fulfil by electric system, are easily and silently done by gas without the least fuss or uncertainty of any kind, and with an entire absence of supervision at any of the points of illumination. More than this, gas is steady; and I only wish any one who says anything about the steadiness of the electric light to try it in the public streets, *in situ*, as I have done. He will soon find that the difficulty experienced by the Irishman in counting one of his little pigs is one of the things still to be got over by the electricians before gas can be abolished.

I think I need not in this paper, which is sufficiently long already, mention anything with regard to the lighting of large spaces by incandescent lamps. Although the colour of the light is more nearly approaching to the proper conditions of useful artificial light, yet it is abundantly clear from the number of lamps always required to light even a very small space, that they do not possess volume. Independently of this, their extreme delicacy will probably preclude their employment in places where delicate fingers are not constantly available for their careful manipulation. These cannot for open spaces, such as squares, railway stations, docks, &c., pretend to any serious rivalry with gas, either in point of usefulness, steadiness, readiness, or cheapness.

As regards the lighting of large interior spaces, such as workshops, in which there are particular dangers from fire to be guarded against, it has been stated and believed by the public that gas cannot so well be employed as electricity. Let me instance the large new workshops of Messrs. Mowlem, Burt, and Freeman, in Westminster, which, after serious consideration on the part of the principals, and visits to electric lighting exhibitions, was finally lighted by gas, after a clearly demonstrative experiment that gas was cheaper, readier, better, and safer than any electric light.

I am authorised by Messrs. Mowlem, Burt, and Freeman, who are thoroughly satisfied with the lighting, to say this. The gaslights, each of which equals 100 candles, are enclosed in lanterns, which are locked, and are lighted by flash jets left burning inside without opening the lamps. Therefore, although there are small shavings constantly flying about from the machinery, none of them come into contact with the lights. The experience of incandescent electric lamps and others does not show them to be any safer than gas.

It is the case that from time to time gentlemen having a very little acquaintance with gas and less with electricity rush into the columns of *The Times* and other journals and give particulars of the cost of electric lighting in comparison with gas. With that delightful archness which arises from their ignorance, they usually omit from these calculations the not unimportant items of rent, rates, and taxes, and the most important item of all—profit. Perhaps under the circumstances they ought to be pardoned this latter omission, as it is generally believed that it has not yet appeared in electric lighting accounts, excepting in the way of speculation.

But I feel that it is needless to weary you and myself with any attempt to demonstrate the relative cost of electricity and gas till some scientific conclusion is arrived at as to what is an electrical horse-power. How is a horse-power to be electrically given to a lamp? What is an electrical candle? What is the proper angle at which electric lights are to be examined; and, consequently, what is the corresponding angle for the gaslight to be tested in comparison with any electric light? Lastly, is the principle that light decreases as the organs of the distances to rule the construction of electric photometers as it does those used for gas? Sufficient for me in this paper, to feel that I have proved that gas is steadier and readier, and more useful for the purpose

Digitized by Google

of lighting large interior and exterior spaces than electricity. *The Times*, in its issue of the 3rd ult., has a leader on the prospects of electricity, and after mentioning that, according to Professor Crookes, the incandescent electric lights will be cheaper than gas, when certain charges incidental to the mode in which he obtains his power have been disposed of, says:—

"It must be remembered, however, both in regard to this and to street lighting, that any comparison now made, in respect either of cost or of illumination, is made with gas very imperfectly applied. Gas when first introduced presented so many advantages over the lights which had preceded it that it afforded an amount of satisfaction in excess of its actual merits, and it is still being consumed in many places on a plan which in the present day may almost be called barbarous. Within the last few years greatly improved burners have been introduced, and the attention of gas engineers has been keenly directed to the subject by the competition of electricity. There are many streets in London which show how much ordinary gas lighting might be improved, and there can be little doubt that the improvements now to be seen are but the precursors of others. It would, therefore, be premature to suppose that the claims of electricity will have to be weighed only against those of gas as now commonly employed, and not against gas employed under more advantageous conditions."

Professor Crookes is a customer of the Gaslight and Coke Company, to the extent of about 500ft. of gas per night for two rooms, which were never before lighted by gas; so that if many of the rich go and do likewise the sale of gas is likely to be increased very considerably for lighting houses and rooms to which it was before a stranger. Messrs. Samuel Brothers, of Ludgate-hill, the well-known tailors, light their show rooms by the Jablochkoff light, which is the nearest electric light approaching to the conditions of a gas burner or candle. They have 20 lights, and employ a gas engine which costs 2s. per hour for gas, and develops 23 horse-power by indication whilst the lights are on. The illuminating power of each lamp is not known at present. Gas is an incandescent light of very large volume as compared to the almost invisible filaments from which the electric light is radiated. The comparison between the two is almost as great as that between the brazier and the electric lamp.

As *The Times* remarks, improvements are continually going on; and I can assure you, from my personal knowledge, that there is a very sharp competition in gas, independently of the outside competition of the electric light. The result of this must and will be improvements in the use of gas and of all kinds of apparatus employed with it. Those inconveniences which generally attend its use now—such as heat and products of combustion—will disappear rapidly; and in saying this I feel I have a much more solid foundation for the expression of my hope than those enthusiasts who make use of the glib assertion, "Oh, they will get over that," to cover all those defects which have been the faithful and never-absent companions of the electric light ever since it made its present appearance four years ago.

The electric light is a scientific light, and so is gaslight; and with all improvements which are capable of being made in both, electricity will find it very hard, when the novelty has worn off, to take a permanent place by the side of gas. It cannot replace it.

THE TELEPHONE FOR COLLIERIES.—A telephone line has been erected between Lord Lonsdale's colliery office in Duke-street, Whitehaven, and the Henry pit, and it is stated that if it works successfully the other pits will be connected in a similar manner. The line has been put up by Mr. Watson Bell. We scarcely think that Whitehaven is likely to prove an exception to the general rule, and, consequently, we shall expect to see telephones multiply in that locality, since there is no doubt as to their extreme utility. We believe that up to the present the mode of communication between the head office at Whitehaven and the various pits has been by special messengers. The advantage of telephones over special messengers need hardly be pointed out.

SUBMARINE CABLES.

The following letter has been received by Mr. John Pender, M.P., from the Board of Trade, under date 1st July:—

"SIR: With reference to former correspondence, and especially to your letter of the 24th of April last, in which you transmit prints of clauses which the telegraph companies represented by you wish to see made law, with a view of protecting submarine telegraph cables from injury, and of preventing impediments to the operations of cable-repairing ships, I am now to offer the following observations:—The Board of Trade have been informed by several other telegraph companies that the utmost measure of protection which they desire is to be protected from 'wilful and wanton or careless injury.' The wishes of these companies seem to be practically satisfied by English law as it at present stands. It appears to have been determined, both at Common Law and in the Admiralty Court, that a vessel whether English or foreign is bound in dealing with the telegraph cable to exercise ordinary skill and care, and that, if either within British limits or beyond them, a vessel does injury to a telegraph cable, which, by the exercise of ordinary skill and care she might have avoided doing, she is liable in damages to the owners of the cable. These points appear to have been decided in 'The Submarine Telegraph Company *v.* Dixon' (1864), C. B., *Law Times*, Vol. X., page 32; and 'The Clara Killam' (1870), *Law Reports* 3, Admiralty and Ecclesiastical, page 161.

"It appears also that any malicious injury to a telegraph cable committed within British jurisdiction, or committed elsewhere by a British subject or a British vessel, can be punished criminally in the courts of this country, under the Malicious Injuries Act, 24 and 25 Vict., Cap 97, Sections 32, 51, 52 and 72, and under the Merchant Shipping Act, 1854, Section 267. If the law of foreign nations corresponds in these several respects with the law of Great Britain, it would seem that all the remedies which are needed in order to satisfy the more moderate demands of the telegraph companies already exist under British law, and it would, therefore, remain to ascertain what is the state of the law of foreign countries on these points. The civil remedy, it is to be observed, is by the law of England applicable, whatever be the nationality of the ship, and wherever the place where the injury is inflicted. The criminal remedy for an offence committed beyond British limits is not applicable in the courts of this country to a foreign ship, and could not be made so applicable without the consent of foreign nations, and they would not be likely to consent to this being done.

"The wishes of the companies represented by you, as embodied in the clauses which accompanied your letter under reply, appear to comprise the following additional proposals:—(*a*.) 'That the Board of Trade shall publish charts with all the telegraphic cables marked on them, and that vessels shall not anchor within one mile of any cable so marked, except in case of stress of weather or other sufficient cause, and shall as far as possible avoid dragging with anchors or trawls near such cables.' To the proposed publication of such charts and the obligations to respect the positions marked in them, there is more than one objection. In the first place, it may not be desirable to give to all the world official notice of the exact position of telegraph cables, but independently of this it appears to the Board of Trade that it is neither just nor practicable to impose such a limitation as is here suggested upon freedom of navigation. The multiplicity of cables is already so great that spaces a mile wide on both sides of each cable would in the aggregate amount to a large fraction of the ocean bed in some seas, and the reservation of such spaces would, therefore, seriously limit the operations of fishing and navigation, and this is without taking into account the possibility of an indefinite increase of the number of cables as time goes on. It must be remembered that cables have only been laid in recent years, whilst fishermen and other seafaring persons have pursued their calling from time immemorial, and if either side is to give way it is not easy to see why it should be the earlier occupiers of the ground who are to be made to yield.

"Further, the difficulties in the way of enforcing such a rule as that proposed against all merchant ships and fishing vessels would be very great, and would involve the necessity of maintaining a fleet of ocean police vessels, in order to prevent the rule becoming a dead letter, whilst on the other hand the irritation which would be produced among fishermen and others, and the disputes likely to result therefrom must also be taken into account. The clauses you suggest go on to provide—(*b*) 'That it shall not be lawful to approach a ship engaged in laying a cable so as to obstruct her operations.' (*c*) 'That if a cable is fouled by an anchor or trawl the persons so fouling it shall take care to do as little injury as possible.' (*d*) 'That persons navigating or fishing near cables shall use the utmost care not to foul or injure them, and if they foul them to do as little injury as possible.'

Digitized by Google

These three proposals seem to be already provided for by the existing English law, as far as is wise or practicable, and the alteration of the international regulations for preventing collisions at sea in respect to the signals to be displayed by cable laying or cable repairing ships which you are aware is in contemplation, will add force to this law. Your clauses then proceed as follows :—(*e*) 'Wilful or negligent cutting or destruction of a cable or removal of a 'telegraph ship or gear to be a subject for damages.' This also seems only to express the existing English law. The next clause provides that—(*f*) 'Any wilful or negligent contravention of the proposed rules is to be also criminally punishable by a penalty not exceeding £50."

"This would be intolerable if applied to the case of a ship merely approaching a cable or a cable-laying vessel, whilst it has yet to be shown that the punishment of offences against the property of a telegraph company is not sufficiently provided for by the Malicious Injuries Act. Finally, it is proposed that:—'(*g*) Officers of Customs shall have power to prevent the use of dangerous trawls.' This is, to say the least, a provision of an extremely doubtful character, and one which it would be scarcely possible to enforce. It has, furthermore, to be remembered that it is much to the interest both of fishing vessels and other ships not to foul telegraph cables; and that, as has been stated by some of the companies, proper care is secured more effectually by establishing and maintaining friendly relations with the fishermen than by the enactment of penal provisions against them.

"Under these circumstances the Board of Trade, as at present advised, would pause before recommending the adoption of the clauses which you have sent to them. But I am to add that Her Majesty's Government are still in communication with foreign governments on the subject.—Yours, &c.,

(Signed) "T. H. FARRER."

THE EASTERN TELEGRAPH COMPANY (LIMITED).

Report of the directors to be presented to the twentieth half-yearly ordinary general meeting and to the extraordinary general meeting, to be held July 13th. The directors submit the accounts and balance-sheet for the six months ended 31st March, 1882. The Company's revenue for this period amounted to £321,810 13s. 5d., from which are deducted £75,140 19s. 5d. for the ordinary expenses and £40,269 13s. 2d. for expenditure relating to repairs of cables during the half year. After providing £2,585 1s. 4d. for income-tax, there remains a balance of £203,814 19s. 6d., to which is added £29,504 9s. 6d. brought from the preceding half year, making a total of £233,319 9s. From this amount there is deducted £22,726 9s. 2d. for interest on debentures, £20,559 1s. 3d. for dividend to 31st March, 1882, on the Preference shares, and £75,000 placed to the general reserve fund, leaving a balance of £115,033 18s. 7d. The directors have during the half year paid an interim dividend of 1¼ per cent. on the Ordinary shares for the quarter ending December, 1881. They now recommend the declaration of a final dividend for the year ended 31st March, 1882, of 2s. 6d. per share, and a bonus of 1s per share, both payable on the 14th inst., making, with the three previous payments on account, a total distribution for the year of 5½ per cent. on the Ordinary shares. The balance of £1,033 18s. 7d. shown at the foot of the revenue account is proposed to be carried forward to the next half year. The general reserve fund, after adding the interest received during the half year, now amounts to £443,535 1s. 7d.; this, with the special reserves stated on the balance-sheet, makes the total amount of reserves £490,816 14s. 6d. The revenue includes £19,500 received for the half year upon the Company's shares in the Eastern and South African Telegraph Company. The reserve funds of that company now amount to £118,695 0s. 11d., and in additon the sum of £37,537 10s. is held by the trustees of the sinking fund for redemption of debentures. The revenue account also includes £2,600 dividend for the half year on the shares of the Black Sea Telegraph Company, belonging to this Company, by which the line is worked and maintained under agreement. The various sections of the Company's cables are in good working order with the exception of the Direct Lisbon line and the 1870 Aden-Bombay cable. The Lisbon end of the direct cable has been recovered and buoyed, but the operations of the Company's ships on the northern end of the line have been delayed owing to the continuance of very rough weather. The repairs to the Aden-Bombay cable have been deferred during the prevalence of the South West monsoon. Owing to the disturbed state of affairs in Egypt, the directors, acting in accord with H.M. Government, have made arrangements to secure telegraphic communication with the fleet at Alexandria in case the connection with the shore should be interrupted. The ss. "Chiltern" has been brought from her station in the Red Sea to Alexandria, and is now there in readiness for further requirements. A concession has been granted by the Emperor of Austria for the laying of a submarine telegraph cable between Trieste and Corfu. The cable has recently been laid by the Telegraph Construction and Maintenance Company, thus placing Austria, Hungary, and the central part of Europe in direct submarine telegraphic communication with this Company's cables in the Mediterranean and Levant. The concession is exclusive for twenty years, and entitles the holders preferentially to the transmission of all official messages and to all private messages not specially directed to be sent by another route. As stated at the last ordinary general meeting, the board have made arrangements for taking over the line and concession, and a resolution will be submitted to the extraordinary meeting empowering the directors to do so at a price not exceeding £67,000. The directors have concluded an arrangement with the Turkish Government for the re-establishment of the connection by telegraph cable between Malta and the Regency of Tripoli, a distance of 220 miles. The cost will be about £25,000. A resolution will be submitted to the extraordinary meeting approving the arrangement. At the extraordinary meeting special resolutions will be submitted authorising the creation and issue of mortgage debenture stock of the Company. It is proposed to create a 4 per cent. stock charged upon the undertaking and revenue of the Company for a total sum not exceeding one-third of the amount of paid-up share capital of the Company for the time being. This is the proportion usually sanctioned by Parliament for mortgages of other industrial undertakings. The new stock is intended to be issued from time to time for conversion or redemption of all the outstanding debentures of the Company, now amounting to £882,000; to provide for the acquisition of the Trieste-Corfu cable and concession, the laying of the Malta-Tripoli cable, and other important expenditures on capital account as and when required. Power will be taken for the Company out of the reserve funds, or moneys voted by the shareholders, to purchase in the market and hold or to cancel and afterwards re-issue, such portions of debenture stock as may be found expedient. The directors believe that by the conversion of the existing terminable debentures, now bearing interest at 5 and 6 per cent., into an uniform Four per Cent. Stock secured as a first charge upon the revenue of the Company, a very substantial saving will be effected, and the finances of the Company placed in a permanently improved position.

RECENT INVENTIONS.

ABSTRACTS OF SPECIFICATIONS.

2482. ELECTRIC MACHINES, *E. G. Brewer.*—*7th June*, 1881.—(*A communication from T. A. Edison, New Jersey, U.S.*) 8*d*.

This relates to the interposition of resistances in the field magnet coils, or in the main circuit, and otherwise regulating and controlling the generation of the current.

3190. FITTINGS FOR ELECTRIC LAMPS, *R. R. Hughes, London.*—*21st July*, 1881. 6*d*.

This invention relates to a number of minor arrangements in order that ordinary gas-fittings may be utilised for electric lamps.

3211. AN IMPROVED PROCESS FOR OBTAINING ZINC FROM ITS ORE AND FROM OTHER MATERIALS, *H. H. Lake, London.*—*22nd July*, 1881.—(*A communication from L. Létrange, Paris.*) 8*d*.

This consists in the application of dynamo-electric or magneto-electric currents to the decomposition of the zinc ore. In the case of *blende*, the ore is roasted at a moderate temperature so as to decompose the sulphates without allowing the sulphur to escape more than is absolutely necessary; the sulphate of zinc thus produced is then dissolved in water and subjected to the action of the electric current, which precipitates the zinc in a metallic state and renders the acid derived from the decomposed salts available for use. When calamine or oxides of zinc are to be treated a sufficient quantity of *blende* is introduced to furnish the sulphuric acid required to form a permanent bath of sulphate of zinc.

3294. AN ELECTRICAL MUSICAL INSTRUMENT, *W. F. Schmoële and A. Mols, Antwerp, Belgium.*—*27th July*, 1881. 8*d*.

This invention is a combination of pneumatic and electro-magnetic apparatus to be applied to a piano, so that the piano may either be played by the keyboard of the apparatus, or the latter may be played as a reed instrument alone, or the music of the piano may be combined with that of the reed instrument. The pneumatic portion of the apparatus provides the motive power, the electro-magnetic portion times and regulates its application. The passage of the current is regulated by a sheet of perforated paper which constitutes the music, and which is drawn forward by rollers at a regulated speed. A series of metallic fingers underlies a metal cylinder connected with a battery, and the perforated paper is made to pass between them. When a finger coincides with a perforation contact takes place, and the current flows to a series of electro-magnets, which instantly raise the pneumatic levers to operate a series of strikers, whereby the keys of the piano are actuated. Means for effecting a gradation of tone, for accentuating particular notes, &c., are also described. The specification is accompanied by detailed drawings of the apparatus.

3305. IMPROVEMENTS IN APPARATUS FOR DISPLAYING AND REGULATING ELECTRIC LIGHT, *Sir C. T. Bright, London.*—*28th July*, 1881.—(*Not proceeded with.*) 2*d*.

The invention consists in regulating the feed of the carbons by the action of two bar electro-magnets, together with a rack and train of wheels.

3435. AN IMPROVEMENT IN ELECTRIC LAMPS OPERATING BY INCANDESCENCE, *F. Wright, London, 8th August*, 1881.—(*Not proceeded with.*) 2*d*.

This relates to a method of clamping the carbons and conductors by means of a block of carbon, without the use of cement.

3437. INCANDESCENT ELECTRIC LAMPS, *F. Wright, London.*—*8th August*, 1881.—(*Not proceeded with.*) 2*d*.

The fibre selected for the incandescent material was that used in making "bass" brooms. The fibre was carbonised and treated in hydrocarbon vapour.

3441. IMPROVEMENTS IN AND APPERTAINING TO APPARATUS FOR GENERATING ELECTRICITY AND MEANS FOR UTILISING THE SAME IN PRODUCING THE ELECTRIC LIGHT, *R. R. Moffatt and S. Chichester, Brooklyn, New York.*—*9th August*, 1881. 8*d*.

This invention relates to an improved dynamo machine and arc lamp. The improvements in the machine consist in an armature having its greatest length of cross section parallel with its axis, and being mounted on a central carrier, with the poles of the exciting magnet so arranged that they will envelop a larger portion of both inner and outer surfaces of the armature cylinder than is usual, thus reducing the amount of resistance to a minimum. Also to the application of iron lugs upon both inner and outer surfaces of the core, so as to cause the latter to be more highly charged owing to its closer metallic proximity. The improvements in the construction of an elecric lamp consist of electro-magnets located in the main circuit, and in a shunt circuit, these magnets acting on armatures mounted on a rocking frame in connection with a brake, so as to regulate the feed of the carbons. The patent specification is illustrated with drawings of the machine and lamp.

3771. AN IMPROVEMENT OR IMPROVEMENTS IN THE PRODUCTION OF VOLTAIC ELECTRICITY, *A. Banks, Birmingham.*—*30th August*, 1881. 6*d*.

This consists in the utilisation of the pickling vats in which iron and steel are cleaned, preparatory to being electro-plated, as generators of electricity. The iron sheets placed in the vat to be cleaned are connected by a metal hook to a rod supported on the top of the vat. In the latter are placed one or more upright porous vessels, the tops of which are above the dilute acid in the vat; in these are placed strong nitric acid and carbon plates. These carbon plates are connected by metal wires. Thus the iron acted on by the dilute acid is the analogue of the zinc in an ordinary battery, and the carbon in the nitric acid is the analogue of the carbon in a Bunsen cell.

3799. IMPROVEMENTS IN THE CONSTRUCTION AND MANUFACTURE OF ELECTRIC LAMPS, *W. Crookes, F.R.S., London.*—*31st August*, 1881. 6*d*.

This relates to incandescent lamps. Having blown his glass globe, the inventor, while the neck is still hot, presses the end inwards with a two-pointed metal tool like a fork, so as to make a hollow projection into the neck, terminating in two hollow points of glass. A small glass tube is attached to one of these, by which the lamp can be exhausted. The neck is then cut in two, and the two points are opened so as to admit of the conducting wires being passed through and sealed in each of the projections by means of white enamel or arsenic glass. Each wire has a small cylinder of glass sealed to it, before it is passed through, so that glass is sealed to glass. The carbon is now attached to the wires, and the two portions of the neck are sealed together again. The lamp is then exhausted by the small tube mentioned above. To overcome the difficulty of joining glass and metal, other than platinum, or the cracking of the glass produced by using thin platinum wires, the inventor uses a compound wire, having a core of copper and a platinum sheathing. The inventor tests his carbons in an exhausted receiver, into which, should one or more be below the standard, a hydrocarbon of some kind can be introduced, by means of which the carbon will be thickened.

3821. IMPROVEMENTS IN ELECTRIC LAMPS OR REGULATORS, *A. L. Fyfe, London, and J. Main, Brixton.*—*2nd September*, 1881. 6*d*.

In this lamp the upper carbon is automatically fed forward by a train of wheels, which train is controlled by the current. The carbon holder and train are capable of receiving from an electro-magnet in the main circuit a slight longitudinal movement bodily in the lamp frame, whereby they are raised for the purpose of separating the carbons and establishing the arc, the brake on the train being actuated by another electro-magnet so as to permit the descent of the carbon holder independently of the train for feeding the carbon as it is consumed.

3871. IMPROVEMENTS IN DYNAMO-ELECTRIC MACHINES, *H. A. Harborow, London.*—*6th September*, 1881.—(*Not proceeded with.*) 2*d*.

This consists of a dynamo-machine with two armatures revolving in opposite directions, and independently if required.

4017. IMPROVEMENTS IN ELECTRIC LAMPS, &c. *S. Hallett, London.*—*17th September*, 1881. 4*d*.

This relates to incandescent lamps. The inventor supports his filaments in a foundation of lime, mounted between two platinised carbon discs, and covers the incandescent portion by a shell of silicon, thereby providing an impervious coating against the action of atmospheric gases, or he places the silicon inside a cylinder of lime. The glass globes surrounding the whole are of the usual shape, and exhausted in the ordinary manner.

4019. IMPROVEMENTS IN GENERATING DYNAMIC ELECTRICITY, *G. E. Dering, Lockleys, near Welwyn, Herts.*—*17th September*, 1881. 6*d*.

This invention consists in improvements in the Grove Gas Battery, whereby the inventor converts it into a cheap and powerful generator of electricity. He substitutes atmospheric air for the oxygen gas usually employed as the negative element, and for the positive certain inexpensive oxidisable gases, such as common coal gas, &c. The inventor stores his gases in large reservoirs, from which pipes lead to the various cells of the battery. Instead of using platinised carbon or platinum for the conductor in contact with the negative gas, the inventor employs ordinary coke, and for the positive conductor he uses an alloy of lead, tin, and a small percentage of other metals, coated with platinum or silver. The inventor obtains better results with spiral or coiled conductors than with flat. The liquid used is acidulated water, as in the usual form of battery.

4024. IMPROVEMENTS IN ELECTRIC LAMPS, *W. Morgan Brown, London.*—*19th September*, 1881.—(*A communication from E. M. Fox, New York.*)—(*Not proceeded with.*) 2*d*.

The object of this invention is to facilitate the construction of incandescent lamps by means of an apertured stop plug, through which the air can be drawn off, so as to obtain a vacuum, and the globe subsequently rendered air-tight by simply turning the plug round. This plug is also used as a support for the conducting wires and carbons.

4058. IMPROVEMENTS IN AND RELATING TO ELECTRICAL CABLES OR LINES FOR TELEGRAPHIC, TELEPHONIC, AND OTHER PURPOSES, *H. H. Lake, London.*—*20th September*, 1881.)—(*A communication from B. J. Henck, jun., Boston, U.S.*) 6*d*.

The object of this invention is to overcome the retardation of electrical signals in long cables or lines. This the inventor accomplishes by causing the various sections of his cable or line to overlap one another in such a manner that a charge of electricity entering upon one section immediately begins to produce its inductive effect upon the next section, and so on.

4059. IMPROVEMENTS IN ELECTRICAL BATH APPARATUS TO BE USED FOR THE APPLICATION OF ELECTRICITY TO HORSES AND OTHER ANIMALS, *H. H. Lake, London.*—*20th September*, 1881.—(*A communication from Dr. B. Barda, Vienna.*—(*Not proceeded with.*) 4*d*.

This is an improvement on the electro-magnetic bath appratus described in patent No. 1107, dated 14th March, 1881, so as to render the same applicable for animals, and especially horses.

4093. IMPROVEMENTS IN OR CONNECTED WITH ELECTRIC CABLES, *E. G. Brewer, London.*—*22nd September*, 1881.—(*A communication from P. B. Delany and E. H. Johnson, New York.*—(*Not proceeded with.*) 2*d*.

This invention is intended to avoid the pressure on the wires of a cable enclosed in a lead pipe, whereby their insulation is endangered, which is effected by forming the intervening lead walls, which separate the various wires, of material which is wholly or partly added to the body of the pipe.

4128. IMPROVEMENTS IN THE METHODS AND APPARATUS FOR DISTRIBUTING AND REGULATING THE TRANSMISSION OF ELECTRICAL POWER, *J. Imray, London.*—*24th September*, 1881.—(*A communication from M. Duprez and J. Carpentier, Paris.*) 6*d*.

This invention consists in the regulation of the transmission of power by electricity. Where a number of machines or lights are worked from the main circuit, the use or disuse of one or more affects all the others. To provide against this, the inventors, instead of connecting each of the lights or machines directly to the circuit, connect each of them to one of two secondary batteries which have been charged from the main circuit, the other of the two in the meantime receiving its charge from the circuit so as to be ready for use when the former is exhausted. The patent is illustrated by diagrams of the connections necessary to carry out the invention, the kind of commutator employed, &c. Other means of regulating the current from dynamos are described, consisting principally in the combination of two machines so that the one regulates the other.

THE EXCHANGE TELEGRAPH COMPANY, LIMITED.

Head Offices--17 & 18, Cornhill, E.C.; Stock Exchange, E.C.; 27, Regent Street, W.

Incorporated the 28th March, 1872, under the Companies Acts of 1862 and 1867, and by Special License from H.M. Postmaster-General.

This Company will undertake to supply recording instruments, telegraphically connected with the Stock Exchange, by the aid of which Subscribers, at their respective offices, may be kept continuously advised throughout the day of the constantly occurring market fluctuations in stocks and shares.

Instruments are placed in the offices of Subscribers and kept in order by the Company, free of every expense but that of rent, and inspectors visit them daily to supply ink and paper.

Terms: £50 per annum, payable quarterly in advance.

Applications for instruments to be made to the Secretary at the above address.

The instruments supplied by the Company can be had to work either on single or double wires, and to print either on a slip or tape of paper, as has hitherto been the custom, or on a broad band of paper in column form.

The Company will supply householders and others with its

DISTRICT CALL SYSTEM.

By the aid of a small automatic telegraph instrument a Subscriber can at any hour, day or night, call a messenger, cab, or policeman, or give the alarm of fire, and will obtain the required assistance within three minutes of making the signal. Subscribers, when absent from their homes for a season, can leave their houses closed, and have them taken charge of by the Company, and rendered perfectly secure against burglars by a telegraphic communication with the nearest District Call Station of the Company, where a policeman will always be in readiness day and night to respond to calls.

Provincial combinations to work under the Company's Patents will be treated liberally.

The Company is also prepared to supply Municipalities with its system of

STREET FIRE ALARMS

as recommended by H. M. Postal Telegraph Department to the Metropolitan Board of Works for the Metropolitan Fire Brigade, and which has received favourable mention by Captain Shaw in his last annual report.

These Alarms have recently been considerably improved by the Company, and are acknowledged to be the simplest yet constructed.

All communications to be addressed to the Secretary as above.

MARSHALL, SONS, & CO., LIMITED,

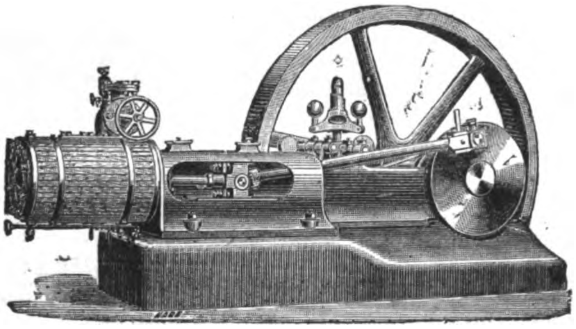
Britannia Iron Works, GAINSBOROUGH, & 3, King Street, Cheapside, LONDON, E.C.

MANUFACTURERS OF

STEAM ENGINES,

Fitted with Patent Automatic Expansion Valve Gear, and

SPECIALLY DESIGNED FOR DRIVING ELECTRIC LIGHT MACHINERY.



OF THE FOLLOWING TYPES:—

HORIZONTAL FIXED ENGINES, with separate Boilers,

HIGH PRESSURE PORTABLE and SEMI-PORTABLE ENGINES,

COMPOUND HIGH and LOW PRESSURE PORTABLE and STATIONARY ENGINES,

As used for driving a large number of the most important Installations in London and the Provinces.

MELBOURNE EXHIBITION, 1881.---Highest Award for all Exhibits. FIVE GOLD MEDALS.
SYDNEY EXHIBITION, 1880.---Two Special First and Four First Prizes.
PARIS EXHIBITION, 1878.---TWO GOLD MEDALS, and other Prizes.

Catalogues in English, French, German, Spanish, or Russian, free on application.

EASTERN TELEGRAPH COMPANY (Limited).—NOTICE IS HEREBY GIVEN, that the TWENTIETH HALF-YEARLY ORDINARY GENERAL MEETING of the EASTERN TELEGRAPH COMPANY (Limited), will be held on THURSDAY, the 13th JULY, 1882, at 2 o'clock in the afternoon, at the Terminus Hotel, Cannon-street, London, when the Report and Accounts of the Directors for the Half-year ending 31st March, 1882, will be presented, a Dividend declared, and the ordinary business of the Company transacted.

At the close of the business of the Ordinary Meeting an EXTRAORDINARY GENERAL MEETING will be held at the same place to consider, and if thought fit, pass Resolutions sactioning the acquisition by the Company of the Trieste Corfu Telegraph Cable and Concession and the laying of a Cable between Malta and Tripoli, and Special Resolutions will be submitted authorising the creation and issue of Mortgage Debenture Stock of the Company to an amount not exceeding one-third of the paid up Share Capital for the time being for redemption of Debentures and other purposes, and regulating the transfer thereof and the powers of the Company in relation to purchasing and dealing with the same.

NOTICE is also given, that the Register of Transfers will be closed from the 6th to the 13th July, both days inclusive.

By order of the Board,

66, Old Broad-street, London, GEORGE DRAPER, Secretary.
5th July, 1882.

TO ELECTRICIANS.—WANTED, by the Birmingham and Warwickshire Electric Light and Power Company (Limited), a thoroughly competent, practical ELECTRICIAN. Application to be made by letter to the MANAGER, 110, Cannon-street, E.C.

WIMBLEDON LOCAL BOARD.

LIGHTING STREET LAMPS.

The Wimbledon Local Board are prepared to receive TENDERS for LIGHTING about 300 STREET LAMPS with gas or otherwise, and lighting and cleaning same at per lamp from the 1st August next to the 31st July, 1883. Lamps to be alight from sunset to 1 a.m. A proportionate deduction to be made from price in respect of each lamp in case of the same not being alight on any night or nights from whatever cause. Penalty of 2s. 6d. per night for each lamp not alight through default of contractor. Formal contract with two sureties required. Payment half-yearly.

Tenders, addressed to me, and endorsed "Tender for Lighting the Street Lamps," to be sent in on or before noon on Tuesday, the 17th July instant.

By order,
W. H. WHITFIELD, Clerk to the Board.

Offices of the Local Board, Wimbledon, 6th July, 1882.

WATER POWER.—To be DISPOSED OF a very large WATER POWER, available for the purpose of Electric Lighting or otherwise. For particulars apply to B. CORCORAN, Jun., 31, Mark-lane, London, E.C. (A. 253.)

INSULATED ELECTRICAL WIRE, Silk, Cotton, or India-rubber covered. Conductivity guaranteed. German Silver Wires for Resistance. Braided Handle Cord, Silk Cord for Electric Bells, &c.—WILLIAM RICKARD, Derby. London Agent (stock kept), EDWIN HOLLOWAY, 2, Gutter-lane, E.C.

Digitized by Google

SLIP

CORRESPONDENCE.—A number of letters are this week unavoidably postponed for want of space.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—This company announce an *ad interim* dividend of 12s. per share.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 30th June amounted to £2,438.

CONSOLIDATED TELEPHONE CONSTRUCTION COMPANY.—This company have declared an interim dividend at the rate of 10 per cent. per annum for the three months ended the 30th ult.

CANADIAN TELEGRAPHS.—The title under which the entire telegraphic system of the Dominion of Canada has been amalgamated is that of the Great North Western Telegraph Company.

PERSONAL.—It is notified that Mr. S. G. H. Barfield has passed the recent examination for D.Sc. at University College, London. His subject was electricity treated experimentally.

ELECTRIC LIGHTING DIFFICULTIES.—It is reported that certain people in Newport, Rhode Island, U.S.A., have been taking advantage of the night to saw down the poles erected for electric light wires in that town.

NEW TELEGRAPH LINE IN AMERICA.—It is stated that the Baltimore and Ohio Telegraph Company is making rapid progress with its new line between New York and Baltimore, which it is expected will be completed by September 1.

TELEPHONY.—We understand that the reports that have appeared in the daily press stating that the bombardment at Alexandria on Tuesday was heard at Malta by means of a telephone connected with the Malta-Alexandria cable, are inaccurate.

THE ELECTRIC LIGHTING BILL.—The House of Commons is to rise for a short autumn recess somewhere about the 8th of August, and it is stated an effort will be made to carry the Electric Lighting Bill through Parliament before the adjournment.

ELECTRIC LIGHT IN NEW YORK.—We learn that the City Hall Park, in New York, is to be lighted regularly every evening by twelve electric lamps supplied by the United States Electric Light Company, at a cost of 70 cents per lamp per night.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 30th June, 1882, were £1,477, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

CUBA SUBMARINE TELEGRAPH COMPANY.—An ordinary general meeting of this company will be held at 61, Old Broad-street, E.C., on the 19th inst., at 1 p.m., to receive the directors' report for the last half year. A copy of this report will be found in another column.

ELECTRIC LIGHT FOR BRIGHTON AQUARIUM.—The Directors of the Brighton Aquarium Company are inviting proposals for lighting up the tanks, corridors, and terraces of the Brighton Aquarium. Further particulars can be had from Mr. J. Wilkinson, manager and secretary.

INSTITUTION OF CIVIL ENGINEERS.—The council of this Institution have awarded to Mr. Alan Brebner, jun., B.Sc., University of Edinburgh, the Miller Scholarship, value £40 a year, for three years, for his paper on "New Forms of Dioptric Apparatus for Electric and Other Flashing Lights."

ELECTRIC LIGHT IN PARIS.—Recently the Municipal Council of Paris decided to light the Monceau Park by means of twelve groups of lights on the Jablochkoff system. An opinion was at the same time expressed in favour of lighting all the important public gardens of Paris by electric light.

ELECTRIC LIGHT IN INDIA.—Sixteen Brush lamps, supplied by the Eastern Electric Light and Power Company have been lighting the Prince's Dock, Bombay, recently. They are to be tried for two months, and if the port trustees are satisfied with the light given, this system is to be adopted permanently.

A POST OFFICE CLERK IN AMERICA.—An American contemporary says:—"Mr. William H. Glover, an operator, formerly employed in the Belfast, Ireland, Postal Telegraph Office, who recently came to this country, has been sent to Chicago to assist in teaching the Wheatstone system to the Western Union operators of that city."

IMPROMPTU ELECTRIC LIGHTING.—During the festivities at Henley-on-Thames consequent on the recent regatta, amongst other things there was to be seen a "roundabout" lighted up, not by the ordinary naphtha lamps, but by two electric arc lamps. This is speculating in electric light with some prospect of a speedy and remunerative return.

GREAT NORTHERN TELEGRAPH COMPANY.—Our Note of last week referring to this company's traffic receipts is somewhat misleading. It should have read as follows:—The traffic receipts of this company for June amounted to £22,560. The total receipts for the months January to June this year were £115,560, as against £114,966 for the corresponding months in 1881, and £108,035 in 1880.

ELECTRIC LIGHT IN THE SEVERN TUNNEL.—We understand that the Great Western Electric Light and Power Company has received an order from the contractor for the Severn Tunnel for dynamo and lamps for lighting up the tunnel during the progress of the works, and that a dynamo to drive forty lights has been sent down, together with its complement of lamps. The Brush system has been in operation for some time at these tunnel works.

TELEGRAPHING FROM LONDON TO INDIA.—Up to about 7 a.m., Egyptian time, or 9 a.m., London time, on Tuesday, the Eastern Telegraph Company's office in Old Broad-street was in direct communication with Bombay, *viâ* the Egyptian land lines, and messages were sent right through from London to Bombay as usual. At this hour, or about then, however, the first shot of the bombardment was fired, and the Egyptians at once cut their land lines and stopped communication.

TELEPHONE COMPANIES.—In the House of Commons, on Thursday week, Mr. Boord asked the Postmaster-General whether he would consider the expediency of granting licenses to more than one telephone company, in order that the public might benefit by competition, as well as by recent and future advances in science. Mr. Fawcett replied that he had already stated the subject was under his consideration, and he could only repeat that there should be no unnecessary delay in arriving at a decision.

ELECTRIC TRANSMISSION OF POWER.—In a recent communication to the Société des Ecoles d'Arts et Metiers, M. J. Chrétien states that the first attempt to transmit motive

Digitized by Google

power by electricity was made at the Vienna Exhibition in 1873 by M. H. Fontaine. M. Chrétien thinks that it is safe to calculate upon the transmission of 50 per cent. of the whole power. Solar heat, he thinks, when transformed into electricity, seems to offer a more desirable solution of the problem than its direct application to the production of steam.

Electric Light at Reading.—During the past week the exterior of the premises of Messrs. Sutton and Sons, the well-known seed merchants, in the Market-place, Reading, have been lighted up by a couple of Brush lamps. An exhibition of Maxim incandescent and other electric lamps is, we believe, opened now in the premises of Messrs. Heelas, Sons, and Co., in Broad-street, Reading. The lamps will be supplied, and the machinery, &c., erected by the Electric Light and Power Generator Company, under the superintendence of their manager, Mr. Massey.

Electric Lighting at Godalming. — A somewhat amusing account of electric lighting in Godalming is given by a contemporary, with a note of interrogation after the word lighting. The paper referred to says:—"A fortnight ago all the lights went out, owing to the wires coming in contact with the telegraph wires and destroying them, as well as, it is stated, the instruments at the post office. On Thursday night one of the arc lights was continually failing, but it was promptly roused into action by the police on duty administering a few kicks to the lamp-post."

The Electric Light at Alexandria.—The *Standard* correspondent on Board H.M.S. "Invincible," which was stated to be lying about seven miles from the Eastern Telegraph Company's cable ship "Chiltern," telegraphs as follows, at 9 p.m., on Wednesday night (Egyptian time):—"The 'Chiltern' is endeavouring to obtain replies to the Queen's message about the wounded, by signalling with the electric light to the various vessels of the fleet. The signals can be read with perfect ease, and could be so were the 'Chiltern' lying at several times her present distance."

Overhead Electric Light Wires.—An accident of a peculiar character is reported as having occurred on the night of Friday week at Brighton. While the members of the local volunteer fire brigade were proceeding to a fire with their escape, it came in contact with the electric light wire overhead, and the current descending the wirework of the escape caused those volunteers who had control to loose their hold. Another member, thinking the machine was falling, grasped the steering rod, and received the full force of the shock, which was so powerful as to bend him double, and disable him for upwards of an hour.

Electric Lighting.—In summing up the evidence given before the Select Committee on the Electric Lighting Bill, Mr. J. Fletcher Moulton said:—"We have had witnesses in the box who have told us that so dexterous is the way in which electricity applies heat to illumination, that you have the incandescent electric lamp, the light of which solely comes from heat, giving a light equal to ten times the light that would be given by gas generating the same amount of heat; in other words, the progress of science has enabled us to get ten times as much light out of the same heat by means of this application of electricity."

Electric Light in London.—We believe that the electric light will shortly be introduced into the houses in the neighbourhood of the Adelphi. Messrs. Coutts and Co., the Society of Arts, and other occupiers of houses in the neighbourhood, have already entered into negotiations with the Electric Light and Power Generator Company for the lighting up of their premises by Maxim incandescent lamps, and there is every prospect of the work being carried out. The underground streets and subways already existing in the Adelphi afford an excellent means of laying the cables into the various houses without incurring much expense.

The Mull Telegraph Cable.—A great deal of inconvenience having been experienced in the island of Mull owing to the telegraphic cable between the island and the mainland being broken, strong representations have been made by various parties to the Postmaster-General and also to the county member, Lord Colin Campbell. In answer to these representations a reply has been received from the Postmaster-General stating that "the Department has secured the services of a ship to effect repairs to the Mull cable, and that the vessel will be despatched in a few days." The ship chartered is, we believe, the "Morna," which has already done good service for the Post Office.

Electricity and Coal.—At a recent meeting of the South Staffordshire and East Worcestershire Institute of Mining Engineers, Mr. H. Johnson, jun., vice-president, read a paper "On Electricity and the Utilisation of Small Coal." He said it had been stated over and over again by electricians that they could carry stored electricity without any appreciable loss. If that were so, he saw great advantages to be derived by electricians and coalmasters alike from bringing the motors to the coal instead of taking the coal to the motors. One of the chief advantages to the company supplying the electricity would be the reduced price of fuel at the pit's mouth, and the non-necessity for expensive sites, as in boroughs. The advantage to the coalowners would be a constant demand for the smallest coal or slack, which could not now be sold at a profit.

The Telephone in America.—The reports for the month of May show that the National Bell Telephone Company of Maine gained 78 subscribers during the month, as follows: Lowell, 22; Worcester, 13; Fitchburg, 8; Portland, 15; Lewiston, 10; Bangor, 8; Calais, 1; Bath, 1; making a total of 3,392 subscribers. The Boston and Northern Company added in May a net gain of 99, as follows: Exeter, Portsmouth, and Dover divisions, 31; Salem and Lynn, 45; Lawrence and Haverhill, 17; Newburyport, 2; Nashua, 4; making the total now connected 1,706. The number of communications over the Boston and Northern Company's extra territorial lines during the month was 8,883. The net earnings of the National Bell of Maine for May were 6,300dols., and of the Boston and Northern Company for the same period 3,863dols.—*Operator*.

Electric Light in Amsterdam.—The Grand Café of Krasnapolsky in Amsterdam has been fitted up with sixty "A" lamps on the Edison system as an experiment. Preparations are, we believe, being made for the establishment of a large central station of 5,000 lights, and we are informed that the building for the station has been purchased, and that the work of laying the foundation for six large dynamos will be begun immediately. These machines will be of the same kind as those at Holborn-viaduct. This work is being carried on by a company in Amsterdam, which has been formed for the working of Holland and her provinces. At Krasnapolsky's a fine comparison between gas, arc, and incandescent lighting can be made, as three adjacent rooms are lighted by each separately. As in other cities, the starting of the plant and its first exhibit produced no little excitement amongst the inhabitants. The work is under the charge of Mr. E. G. Acheson, electrician to the Edison Company in Holland and Belgium.

Deservedly Punished.—At Hammersmith Police Court a few days ago Philip Hillier, a boy living at Kensal New Town, appeared to answer a summons charging him with maliciously damaging some insulators attached to telegraph poles, which were the property of the Postmaster-General. It was proved by a constable that the defendant discharged a stone from a catapult at and broke an insulator attached to the telegraph wires by the side of the canal. The catapult and a number of stones were found upon the defendant. It also appeared that two insulators on the pole were broken. Mr. George Robert Judkin, an inspector of post office telegraphs, informed the magistrates that during the last three years above 3,000 insulators had been broken, at an expense of £172, two-thirds of the damage having been committed between the gasworks at Kensal Green and the Mitre Bridge. Mr. Paget committed the boy for 21 days, refusing an application of his mother to impose a fine. We hope that this will be a lesson to the boy in question and his fellows which will bear fruit. Boys who throw stones at trains or at telegraph posts must be taught, by strong means if milder ones will not avail, what great mischief may result from such amusements.

Electric Lighting of Trains.—Interesting experiments in lighting trains by electricity were recently carried out by the Paris-Lyons and Mediterranean Railway under the direction of Messrs. Jousselin and Mors. The train experimented with was composed of two first-class carriages with break van in front and rear. The front break van and the two carriages alone were lighted by electric light; the van by two Swan incandescent lamps, the carriages, which had four compartments each, by one such lamp in each compartment. Altogether ten Swan lamps were used of twenty candle-power each. The current was supplied by an A Gramme machine, placed in the front van, and which was set in motion by a belt and pulley fixed on one of the axles of the van. The current was not only utilised to feed the lamps, but also to charge Faure accumulators, constructed by M. Reynier. There were thirty of these weighing twelve kilogrammes each. The current from the machine was shunted through the lamps and the accumulators, the latter being charged whilst the train was in motion; at the moment of stoppage an automatic commutator broke the circuit between the dynamo machine and the accumulators, and the latter continued the supply of current to the lamps alone.

A Temperature Regulator.—In a recent number of *La Nature* Dr. Regnard describes the following apparatus for regulating temperature:—"In a bath of water an electrical thermometer is immersed, the upper end of which is open, and in the tube of which a platinum wire dips, which can be raised or lowered, or fixed opposite any particular degree of temperature. The mercury in the bulb of the thermometer is in connection by means of a wire soldered into the glass, with one pole of a Daniel cell, the platinum wire above mentioned being connected by another wire to the other pole of the cell, the circuit being complete when the mercury in the thermometer and the platinum wire are in contact. In the circuit is inserted an electro magnet, the armature of which is furnished with a long lever, which in turn carries a small petroleum lamp. When no current passes this lamp is in position under the bath of water. When a current passes the armature of the magnet is attracted and the lever withdraws the lamp to a distance, and the bath, consequently, is no longer heated by it. Almost immediately the thermometer falls and the mercury breaks contact with the platinum wire the current is at once broken, the electro-magnet becomes inactive, and a spring, acting in opposition to the armature lever, brings back the lamp to its old place under the water bath."

Why the Electric Light Goes Out.—The following reasons are given by Messrs. Siemens Brothers for the failure of certain of thier lamps at different times during the period for which they lighted their district of the City, that is from 1st April, 1881, to 31st March, 1882. We extract the particulars from a report presented to the Commissioners of Sewers by Mr. W. Haywood, their engineer. Accidental falling off of one of the machine belts accounted for the extinguishing of several lights, damage to cable caused by barges passing under London Bridge for others. Then come such items as:—"Soft places in carbons," "strap of exciter broke," "belt of machine slipped off pulley," "burnt dimly on account of soft places in carbons," "spring holding commutator brush gave way," "engine driver letting down steam," "accident to machinery," "breaking of a lace in leathern belt," "short circuited," "strap of machine broke," "an accident occurred at the engine house," "lamps required cleaning," "owing to irregular consumption of lower carbon," "lamps required cleaning, owing to fog and 38½ hours consecutive run," &c. The number of lamps reported as defective during the year in Messrs. Siemens's district was 320, and the total number of hours for which they were defective was 831 hours 54 minutes. 126 lamps are reported to have gone out owing to defective machinery during the year, 34 owing to defective cables, 124 owing to defective carbons, and 36 defects are classed as miscellaneous.

Egyptian Telegraphs.—The following letter from Mr. Frederick George, Deputy Inspector-General of Egyptian Government Telegraphs, appeared in *The Times* for July 13:—"Sir: Referring to a letter signed 'E. A. Floyer,' which appeared in *The Times* of the 19th ult., and the very proper reply given thereto by Sir James Anderson, the managing director of the Eastern Telegraph Company, the following day, I feel it my duty, as the responsible manager of the Egyptain Government Telegraph Service, to explain that no interruption whatever has occurred in the telegraphic communication between Europe and the capital of Egypt in consequence of the temporary closing of the Eastern Company's office at Cairo, as would appear to be implied by the letter above referred to, seeing that messages are daily interchanged between our own and the Company's central station at Alexandria for Cairo. As regards the last paragraph of the letter, I have only to state, from very long experience in the Egyptian Government Telegraph Service, that we have always received every courteous and practical facility from the said company by being allowed free use of their wires when our own communications have been interrupted, and occasionally (as I know personally) to the detriment of their own traffic, so far as slight delays are concerned. Since the temporary closing of the Company's office at Cairo their wires were kindly placed at our disposal, which offer I have gladly availed myself of for the Government service during the unusual and excessive pressure of business, occasioned by the critical state of affairs at present existing in the country." This letter is dated Alexandria, July 3. Both the above letters were reprinted in *The Electrician*.

Thunderstorms.—Severe thunderstorms are reported as having taken place in various parts of the country on Friday last and subsequent days. On Friday evening, between five and six o'clock, a storm burst over the district of Morton, Ringland, and Cossey, in Norfolk. A flash of lightning struck a thatched double cottage at Ringland, occupied by two families, named Fiddy and Bales, and set it on fire. The

Digitized by Google

building was burnt down, and two of the occupants severely injured by the flames. On the previous Thursday heavy storms were experienced in Scotland.—On a farm at Balnamoon, near Brechin, two horses that were grazing in a field were struck by lightning, and killed.—During Saturday afternoon a violent storm of thunder and lightning passed over Manchester. About five o'clock, immediately after a vivid flash of lightning, a crash was heard by the occupants of the Wheatsheaf Hotel, situated in High-street, one of the busiest thoroughfares in Manchester, as if timber was falling. The house was full of customers, who had sought shelter from the rain, and a rush was immediately made for all the means of exit, which were, fortunately, numerous. The people had scarcely reached the street when the building fell in bodily. When those present had recovered from the fright into which they had been thrown an examination was made, and it was found that the lightning had struck the roof, which in falling carried all before it, until the house was razed to the ground, leaving only the front wall and the back part of the premises standing, and these were so much damaged that they might fall at any moment. Several persons had very narrow escapes, but, fortunately, no one was hurt. The manager of the house hearing the crash, and coming to an immediate conclusion that the house had been struck by lighting, rushed into the cellar and turned off the gas, fearing that the lightning might fire the house, which contained a large supply of spirits.—At Mapperley, near Nottingham, on the same day, a man and his son were sheltering from the rain in a plantation, when the former was knocked down by a flash of lightning, and rendered insensible. He recovered shortly afterwards, however, and was taken home.

A Submarine Detector.—The importance of being able readily to discover the locality of a submerged torpedo or a metallic obstruction in time of war, or of lost anchors, chains, or electric cables in time of peace can hardly be over-estimated, says *The Times*, and hence the value of a submarine detector the working of which we have recently seen demonstrated. This instrument is the invention of Captain M'Evoy, who is well known in connection with submarine engineering and torpedoes, in which he has from time to time introduced some very marked improvements. The apparatus consists of a small mahogany box, in which there is a pair of coils or bobbins, a vibrator similar to that employed in electric bells for making and breaking contact, and a telephone. To this box is attached a given length of flexible cable, with four conducting wires in it. To the other end of this cable is attached a flat wooden case, in which there are two coils. This case is weighted, so that it will readily sink when placed in the water. There are also terminals on the box for attaching battery wires, and an arrangement for putting on and cutting off the current is provided. There are two complete circuits through the box, cable, and wooden case, the one primary and the other secondary. The battery, the vibrator, one coil in the box and one coil in the wooden case are in the primary circuit, while the telephone, one coil in the box, and one coil in the wooden case are in the secondary circuit. When the battery is on, the coils in the box are adjusted so that little or no noise from the make-and-break action of the vibrator is heard in the telephone. When thus adjusted the instrument is ready for work, and if the wooden case is then brought near a metallic body a loud noise is heard in the telephone, thus indicating the proximity and locality of such a body. The principle upon which this invention is based is that of the induction balance of Professor Hughes. In Captain M'Evoy's apparatus the application of the principle to the detection of the presence of metallic bodies through the sense of hearing has been worked out in a very ingenious and equally practical manner. The instrument cannot fail to prove invaluable in discovering and locating the position of the objects we have mentioned, as well as in indicating the whereabouts of sunken ships, helping to recover treasures, and in assisting generally the operations of divers.

Telegraph Clerks' Grievances.—A meeting of the Leicester Branch of the Postal Telegraph Clerks' Association was held on Saturday evening last, to consider the action of the authorities in calling upon Mr. Crighton, of Liverpool, one of the delegates at the Annual Conference, held at Anderton's Hotel on June 25, to verify statements made at that Conference to the effect that the revision was not a good one, official favouritism having too much to do with its administration, and "that the great majority of the telegraphists were totally ignored, 90 per cent. of them having no immediate benefit."—A Senior Clerk moved the following resolution :—"That this meeting expresses its regret that the Department should have deemed it necessary to attempt to curtail our freedom of speech by calling upon Mr. Crighton to explain his remarks at the Annual Conference, that gentleman having only expressed the opinion of the majority of telegraph clerks, as has been clearly manifested by the reports that have appeared in the public press of numerous meetings held in many different towns, condemning the unjust and partial application of the scheme, and also by the large number of petitions that have been forwarded to the Postmaster-General praying that it might be reconsidered; this meeting, therefore, trusts that the Postmaster-General will grant to telegraph clerks the same freedom to ventilate their grievances that he has hitherto permitted." The mover cited cases which happened at Leicester and Peterborough to support the allegation of official favouritism in the matter of the superior appointments, and said the other statements of Mr. Crighton required but little corroboration. The percentage of the third-class clerks in Leicester who received no immediate benefit from the revision scheme was 83·4, and the fact that the provincial clerks still had to perform an average of two hours per Sunday without remuneration was sufficient to bear out another statement which had been challenged.—The resolution was seconded by another Senior Clerk, and carried unanimously.—Another meeting of telegraph clerks was held on the same day at Birmingham, the object of which was to receive a report on the recent Conference from their delegate, Mr. Haslam, who was thanked for his services. The following resolutions were unanimously adopted:—"That this meeting endorses the resolutions of the Conference, and as there appears to be no means of a satisfactory settlement of the grievances of the postal telegraph clerks except by means of a Select Committee, earnestly appeals to the telegraph staff at all offices to endeavour to secure the support of their Parliamentary representatives to Mr. Macliver's motion." "That this meeting supports the statements of the Liverpool delegate at the Annual Conference in the following clauses as regards this district:—'(1) That the late scheme of revision was applied in an unjust and partial manner, and that official favouritism had to do with its administration. (2) That in the lower classes 10 per cent. only of the staff received substantial benefit. (3) That the scheme of revision is unsatisfactory, because promotions in the future as well as in the past depend principally upon official selection, and not upon any standard of efficiency.'" "That this meeting pledges itself to render all support possible to Mr. Crighton, the Liverpool delegate, should circumstances render it necessary."

THE CRYSTAL PALACE EXHIBITION.

Post Office Exhibits.

(CONTINUED FROM PAGE 138.)

The *Single-current Duplex Direct Ink-writer* is rather a big title, nevertheless we will try to dissect it. "Single-current" means a mode of sending currents of electricity always in the same direction; "duplex," a method by which the operator at *each* end of a wire can send a message simultaneously; and "direct ink-writer" because the current sent acts upon the receiving recorder directly without any supplementary aid, and writes its characters on a paper ribbon in ink. This apparatus consists of a lever, or *key* for signalling purposes; a galvanometer which indicates the presence or absence of currents, as well as faulty conditions of the circuit; clockwork for drawing the paper tape between two rollers at an uniform speed; an electro-magnet which actuates a lever so as to raise an inking disc into contact with the paper band; a switch for converting the system into *simplex* or *duplex*; and a rheostat, or box containing different lengths of fine wire for interposing various resistances in the path of the current when working duplex so as to represent an artificial line. We learn, then, that Fig. 8 can, by means of a switch, be made to work simplex or duplex, that is, single or double. In the following diagram (Fig. 9) B represents the electro-magnet just below a cylinder of soft iron secured to lever C. The signalling key is at A. The receiving and sending stations are both shown.

Now, if we imagine the current traversing the wire as pointed out by the arrows, it will be seen that all an operator has to do in order to form an electrical circuit is to fill up the small gap at the key marked a and a^1. Short or long depressions of the key make short or long ink signs on the paper; and note further, that the sending clerk does not want his own signals to appear on his own receiving tape. Hence, the fulcrum of the key permits of the receiving instrument being isolated when the key is depressed and the current being sent out to line and the distant instrument. The play of the key is about 1-24 or 1-32 of an inch.

If the ink-writing portion were detached from the magnet and armature lever at *d*, then the simple, comparatively inexpensive, "sounder" instrument would be sufficiently represented. As the free end of the lever plays against the two metallic stops two distinct sounds are heard every time the electro-magnet attracts the armature. Short, or slightly-prolonged intervals between these two sounds indicate the *dots* and *dashes* of the Morse code. Practical experience proves that the ear is as true as the eye; in fact, fewer errors occur from sound reading than from sight, though the signs be actually written. More work can be done when an acoustical *receiver* is employed. It is far easier and quicker to write from dictation when the words emanate from a clear, steady, voice, than it is to write from a copy; and for similar

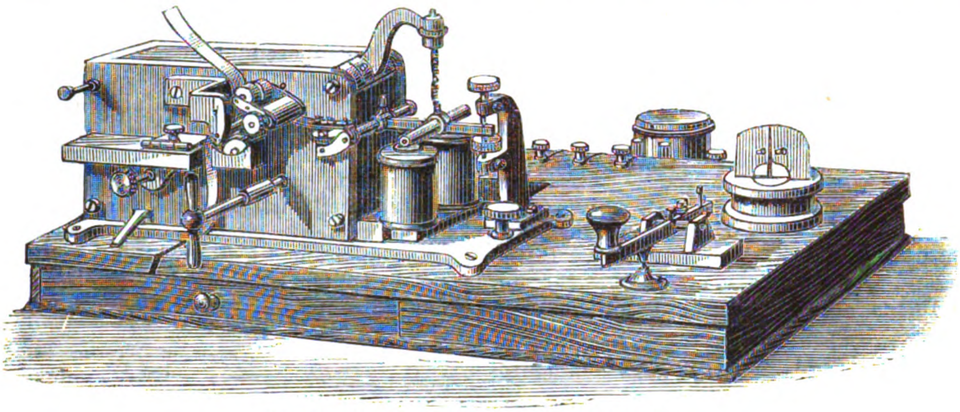

FIG. 8.—Single, or Duplex, Direct Ink-writer.

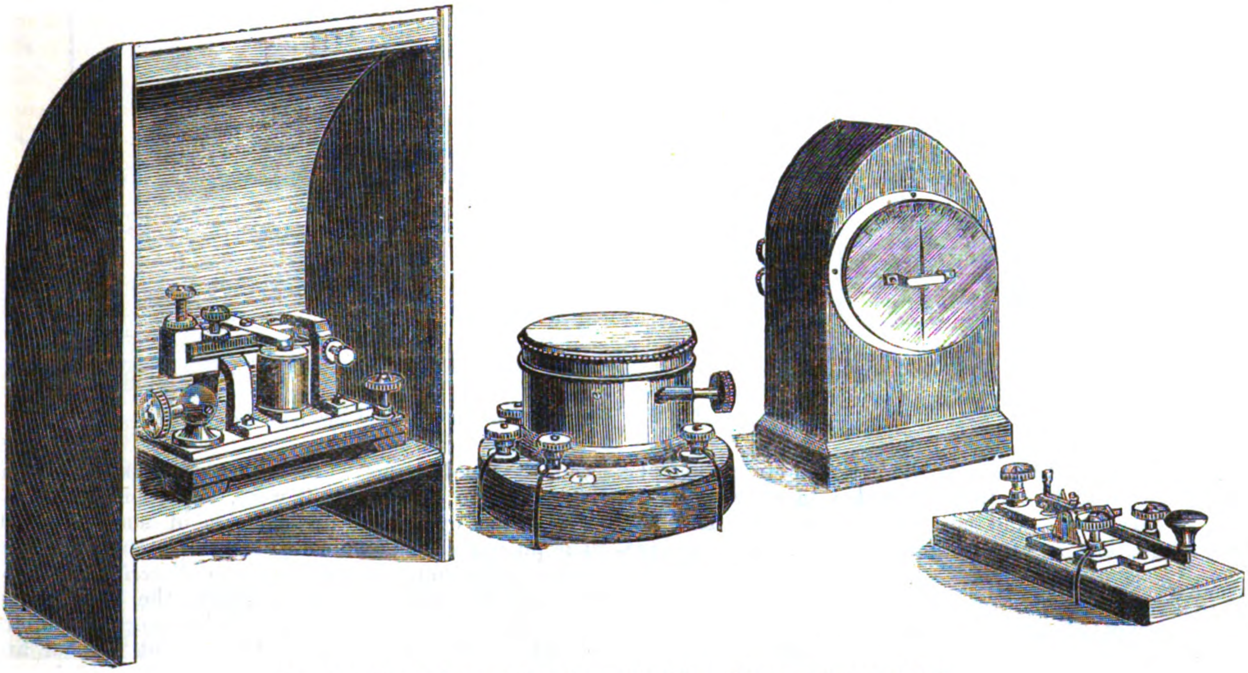

FIG. 10.—Single Current Sounder, with Relay, Galvanometer, and Key.

Digitized by Google

reasons an expert clerk can read and write at a speed of thirty-five words a minute from the "sounder."

If the signals of an ink-writer or sounder vary in strength from any cause whatever, or the arriving current be feeble, then a *relay* is added. A relay is a delicate electrical device

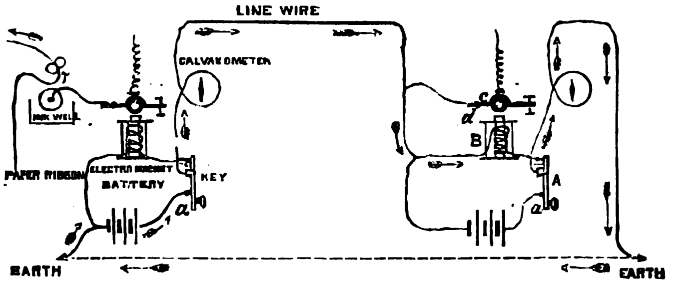

Fig. 9.—Electrical Connections of a Direct Ink-writer, or Sounder Circuit.

which, when operated by a distant station's current, joins up a local battery through the receiving instrument. It thus *repeats* the signals, and the ink-writer, or sounder, therefore responds with the full vigour of the local battery, however can in this way be obtained than if a spring performed the office of the permanent magnet. Fig. 11 is a graphic representation of a working circuit comprising single current sounders, relays, &c., as depicted in Fig. 10.

If we substituted a *double current key* in place of the single current key above, our readers would have before them the *double current sounder circuit.* This key reverses the current after each signal without disconnecting the battery from the line wire, and is put on circuits either defectively insulated (that is, where a considerable proportion of the electricity sent into the wire leaks out to the earth, and is wasted), or on long lines—especially such as consist of both ærial and submarine, or subterranean lengths, or those composed of nearly all gutta percha-covered conductors lying in close proximity to the ground. The key has about 3-16 of an inch play, and is so constructed that during the operation of signalling the current is prolonged so as to produce the necessary charge and a condition of the line suitable for actuating the receiving instruments. Still, the speed of working is slower than on single current circuits, not solely on account of the before-mentioned loss of current, and the longer duration of battery contact for charging the line, but owing to the fact that matter surrounding the wire is influenced by the current,

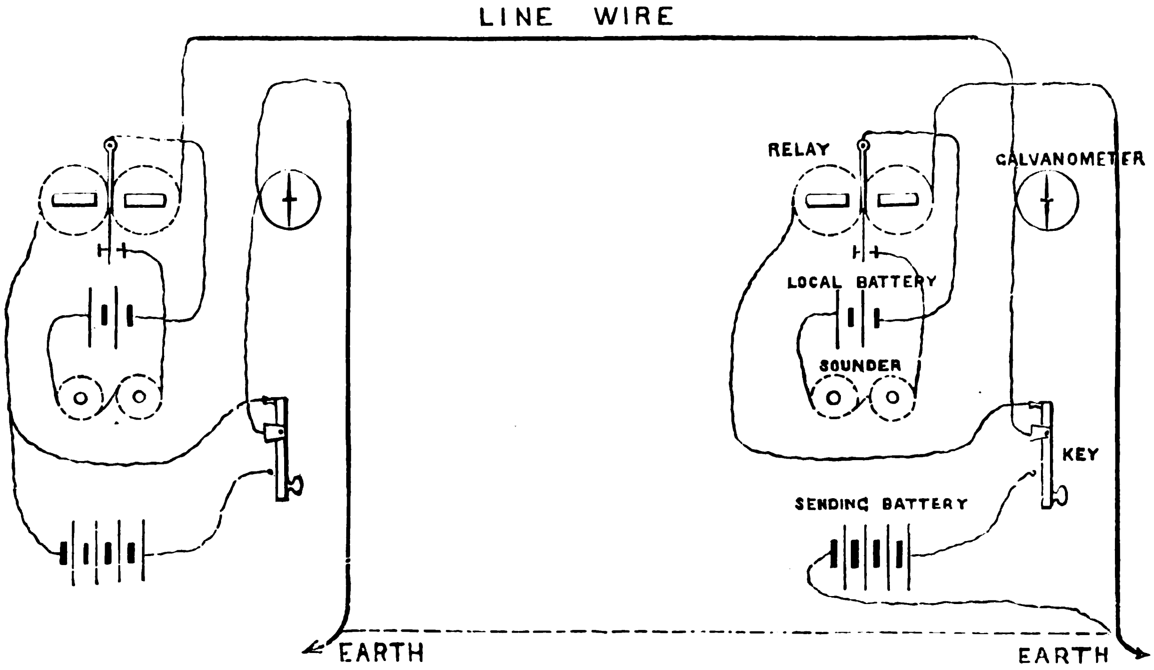

Fig. 11.—Showing Arrangements for a Single Current Sounder and Relay Circuit.

different the electrical effects of the external circuit may be. *Polarised* relays, such as those included in above diagram, contain a permanent and an electro-magnet. The permanent magnetism is an antagonistic force to the electro-

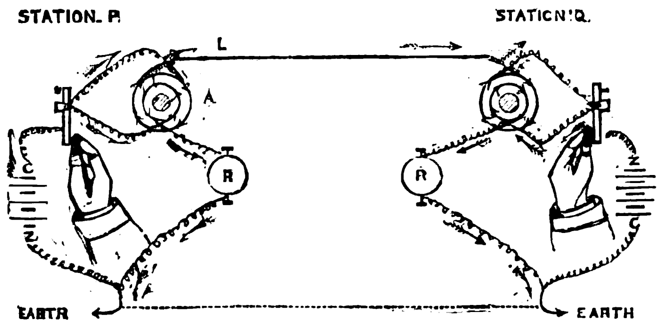

Fig. 12.

magnetic energy, and serves to break the local battery circuit by replacing a light, movable, magnetic bar, after it has been attracted by the electro-magnetism to its position of rest when no current circulates. A much finer adjustment and the dual attractive forces set up cause a portion of the electricity to become, as it were, superficially *bound* on the wire, thus opposing the progress of succeeding currents. The phenomenon is known to telegraph engineers as electrostatic induction. By altering the *direction* of the current through the wire after each signal, the retarding effect is reduced, and, moreover, the electro-magnets in circuit respond quicker; hence a double current key, or any other similar reversing current method, accelerates the transmission of signals over certain lines upon which signalling would otherwise be very slow indeed.

The Duplex, or two-way system of simultaneous transmission in opposite directions on one wire, is not new in principle. Its development was gradual from 1853 to 1872, when, through the exertions of Mr. J. B. Stearns, the system became practicable. He found that the chief impediment was due to electrostatic induction, and surmounted the difficulty by employing in an artificial line an apparatus for accumulating the same electrostatic charge as that on the surface of the line, or, in other words, used a condenser of varying capacities. Fig. 8 represents the class of instrument usually employed for short distances; that used on duplex lines of considerable length will be represented on another occasion.

Digitized by Google

The principle of a duplex direct ink-writer (Fig. 12) may be illustrated thus:—

Here we suppose A to be an electro-magnet wound with two lengths of wire instead of one, and joined up in the way shown. Each wire has the same resistance. At R is placed a rheostat (a set of resistance coils, *i.e.*, bobbins of insulated fine wire of known value, or for our present purpose we will say an artificial line). Now, just as water flowing through a main pipe can be caused to supply branch pipes with like or unlike quantities, so with electricity and conducting wires. If station P were sending to Q the current would divide at the fulcrum of his own key between the arms of the circuit R and L, and would move round the distinct coils of wire enclosing the soft iron cores in opposite directions, producing thereby equal and contrary electro-magnetic effects, resulting in the soft iron cores remaining neutral. We have a balance of power, obtained by making the resistance of R, say, equal to L. This so-called balance is indispensable, because while it is essential that the outgoing current shall circulate through the *receiving* instrument at the *sending* end, no self-made signals shall appear upon the home receiving machine, yet the instrument must be ready at any moment to be influenced by the distant operator. Let us, however, proceed:—The current, bifurcated at the fulcrum, half goes through the artificial line R, and half through the real line L on to Q. At Q we find the current traversing the helices in the *same* direction, rendering the cores magnetic and creating a signal. The effect would

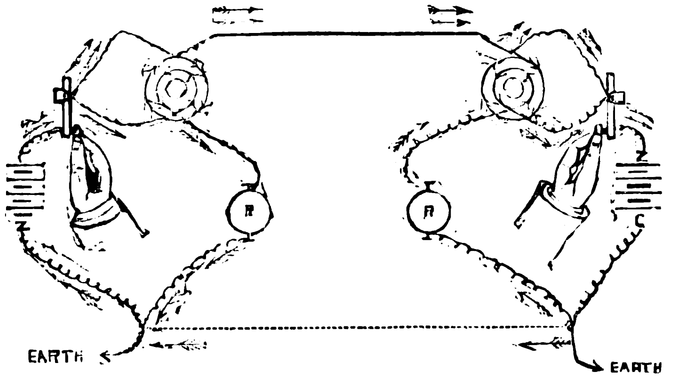

FIG. 13.

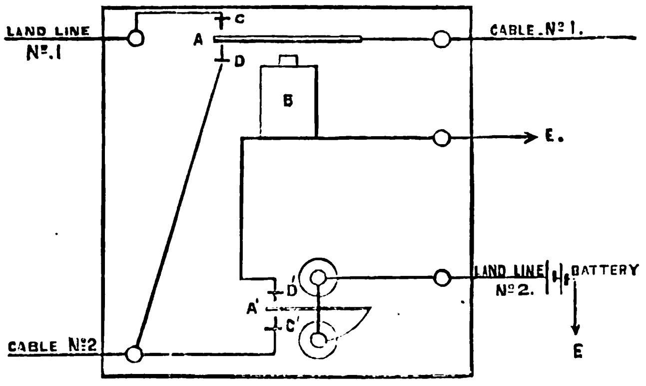
be similar if Q signalled to P, but if both operators depressed their key simultaneously then the one battery would help the other, causing the principal current to flow through the coils of wire communicating with the real line; consequently, the balance would be destroyed, the cores would be magnetised, and a signal received at each end of the wire. Fig. 13 indicates the path of the current when two stations send at the same time.

(TO BE CONTINUED.)

Saunders and Kennelly's Cable-house Switch.

The object of this arrangement is to enable an intermediate station (some distance from the landing point of the cable, connected by aerial lines to the cable-house) to either put the aerial lines in connection with the cable for working direct to the terminal stations, or to join the stations through so that the terminal stations could work direct with each other, and thus avoid the inconvenience of badly-insulated aerial wires being in circuit with the cables when the terminal stations were working direct. The action is as follows:—When the land-lines are connected to the cables the armature A of the electro-magnet B rests upon the contact C, putting cable No. 1 direct to land-line No. 1. The tongue A' of the relay rests upon the contact C', and connects cable No. 2 through the coils of the relay to land-line No. 2, the relay tongue being kept over by a spring sufficiently strong not to be affected by the working current. When it is required to join the cables through for direct working between the terminal stations a battery is connected, one pole to land-line No. 2 and the other to earth. This has the effect of throwing the tongue A' of the relay over to contact D', by which the current passes through the electro-magnet B to earth, causing the armature A to make contact with D,



Saunders and Kennelly's Cable House Switch.

thus joining cables 1 and 2 together so long as the battery is kept on. When the battery is taken off the tongue of the relay, A' is drawn by the spring back to contact C', and the armature A on to contact C, thus again connecting the cables to their respective land-lines.

DESCRIPTION OF THE EDISON STEAM DYNAMO.

BY T. A. EDISON, PH.D., AND CHARLES T. PORTER.*

The central Edison station of the first district in New York City will, when fully equipped, be supplied with twelve dynamos, each of which is nominally rated as a 1,200 light machine, at 16 candle-power incandescence, but is capable of supplying 1,400 lights of this power, continuously, and with high economy, without heating the armature, or burning or injuring the commutator or brushes. This increased capacity is due to improvements in the lamp itself.

The armature of each dynamo is driven by a Porter-Allen engine, of $11\frac{3}{16}''$ diameter of cylinder by 16″ stroke, directly connected, and making 350 revolutions per minute, giving a piston travel of 933 feet per minute.

The steam is supplied by eight Babcock and Wilcox boilers, of 2,000 aggregate horse-power, and which will work under a pressure of about 120 pounds. These occupy the basement of the building. Over them, the first and second floors being removed, an iron superstructure is erected entirely separated from the walls of the building, and on this the combined dynamos and engines are placed.

One-half of this equipment is now nearly ready for service, and the remainder is expected to be completed during the coming season.

The armature of the dynamo is of the form commonly known as the Siemens armature, but in its construction and "connecting up" it differs radically from all others.

The foundation of the armature, or the iron core which is built upon the shaft, is made up of sheet iron discs, separated from each other by sheets of tissue paper, and bolted together. This has all the advantages of a solid iron core in strengthening the magnetic field, while it completely prevents the great loss of power by local currents, which would circulate in the iron if it were solid. In the place of insulated wires, the cylindrical face of the armature is made up of heavy copper bars, trapezoidal in section, each bar being insulated and also separated from its neighbours and from the iron core underneath by an air space.

The connection between the bars on opposite sides of the armature, to form the electrical circuit, is made by copper

* A Paper read before the Philadelphia Meeting of the American Society of Mechanical Engineers, April, 1882, and published in the *Journal of the Franklin Institute* for July.

Digitized by Google

discs, of the same diameter as the core. At each end of the core are one-half as many of these copper discs as there are bars, each disc being insulated from its neighbours, and the whole being bolted together in such a manner as to form, with the discs of sheet-iron constituting the core, one solid mass. Each disc is formed with projecting lugs on its opposite sides, to which the two bars are connected.

The connections between the opposite surfaces of an armature are of no benefit in generating an electric current, but are a necessary evil, introducing useless resistance into the circuit. By using for this connection copper discs in the manner described a great weight of copper is disposed in a limited space, and so this useless resistance, and consequent loss of energy, is reduced to a minimum.

This method, moreover, reduces the work to a simple machine construction, in which all the parts are duplicates, and the operations can be much cheapened and facilitated by the use of special tools.

The spaces between the armature bars admit of a free circulation of air, thereby preventing the accumulation of heat, and increasing to an enormous degree the capacity of the machine. The armature is at intervals wound with piano wire over the bars to resist the centrifugal force developed by their revolution.

The commutator and brushes of an electrical machine are the parts subject to the greatest depreciation. In this machine all parts of the end of the armature are so constructed as to be easy of access, and they can be quickly and cheaply repaired, or removed and replaced by new parts when necessary. Any accident would require but a short stoppage for repairs.

Provision is made for keeping a continuous and rapid circulation of air over the entire face of the armature.

This armature is 27·8″ in diameter by 61″ long. The commutator adds 18″ to this length, and is itself 12¾″ in diameter. The armature shaft is of steel, 7¾″ in diameter, having a total length of 10′3″. The journals are 6½″ in diameter by 15″ long, and run in Babbit metal bearings in pillow blocks of the box form, giving the greatest stiffness with minimum of weight.

Provision is made for continuous water circulation underneath the boxes, and for continuous lubrication, with traps to prevent the creeping of the oil along the shaft and reaching the commutator, and drains to receive it as it runs through the bearings and convey it to a drip pan.

The magnet is made up of two immense cast-iron "pole pieces," between the semi-cylindrical faces of which the armature revolves, twelve cylindrical soft iron cores attached to these pole pieces, and made magnetic by an electrical current circulated in the wire wound around them, and four soft iron keepers connecting the back ends of the cores. Eight of the cores are attached to the upper pole piece, and four to the lower one.

The width of these "poles" is 49″, and their height 61½″. The length of the twelve soft iron cores is 57″, the diameter of the eight upper ones is 8″, and of the four lower ones 9″.

The four soft iron keepers are each 11″ wide by 9″ in thickness, and the total length of the magnet is 94″.

The magnet is insulated by cast zinc bases 3″ in thickness.

The weight of the dynamo is as follows:—

Armature and shaft	9,800 lbs.
Two pillow blocks	1,340 ,,
Magnet, complete	33,000 ,,
Zinc bases	680 ,,
Total	44,820 lbs.

The copper is distributed as follows:—

In the armature bars	590 lbs.
In the armature discs	1,350 ,,
In the magnet wire	1,500 ,,
Total	3,440 lbs.

Mr. Edison was early impressed with the conviction that to give steady and reliable motion to these armatures it would be necessary to connect an engine to each one of them directly. This combination has been termed by him the steam dynamo.

In adapting the Porter-Allen engine to this service, a special construction in some respects was found to be called for. These special features will be briefly described.

It seemed important to avoid a rigid connection between the engine and the armature shafts, which would require the entire series of bearings to be maintained absolutely in line. In place of this, therefore, a self-adjusting coupling has been introduced, of the form shown in Fig. 1, which will permit of considerable errors of alignment without any abnormal friction being produced in the bearings.

The point of difficulty was the backlash, the engine having no fly-wheel except the heavy armature itself, which was to be driven through the coupling. Provision was made for taking this up by steel keys of a somewhat peculiar form, between which the tongues of the couplings move freely, while they themselves are immovable. These keys are held between set screws threaded in wrought iron rings covering the flanges on the ends of the shaft. All the faces liable to move upon each other are oiled from a central reservoir. This coupling is a very compact affair, without a projection anywhere above its surface, and gives every promise of completely answering its purpose. The engine is made with a forked bed and two shaft bearings and double crank, and so is completely self-contained.

The shaft having no support beyond these bearings on either side, unusual stiffness was required in the crank pin to prevent deflection under the great strains to which it is

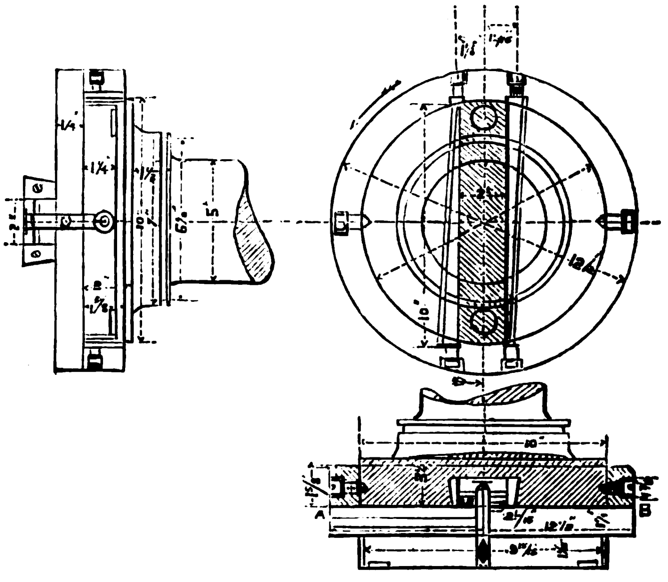


FIG. 1.

subjected. A novel form of pin was proposed by Mr. Richards, which is found to possess all the rigidity required. It is provided with flanges which are let into each crank, and held each by four screws, while the shanks of the pin are also forced firmly into the cranks. Special appliances enabled the work of putting the cranks together in this manner to be done with extreme and uniform accuracy.

The engine is so arranged as to have the valve gear on the side furthest from the dynamo, when running, for any purpose. The connecting rod is of steel, and the crank pin boxes are formed directly in the end of it. This end is finished from a solid forging, and chambered out for Babbit metal. The bolts are then fitted, after which it is parted, and holes are drilled for holding the Babbit securely.

In the connecting rods for single crank engines of this type, permanent length of rod is secured by forming the crank pin end solid, and taking up the wear by a wedge closing up the inside box. In these double crank engines this construction is impracticable, but the same object is attained by forming the crosshead end in such a manner that the strap is made permanent, the inside box being closed up by a key bearing against a steel plate.

Digitized by Google

The weight of the reciprocating parts of this engine is as follows:—

Piston, with rod	83 lbs.
Crosshead	42 „
Connecting-rod	109 „
Total	234 lbs.

The initial acceleration of this mass, or the force required, on the dead centres, to give it the motion necessary to relieve the crank from strain, is as follows:—

$$350^2 \times \cdot 66 \times \cdot 000341 = 27\cdot 57,$$

or 27·57 times the weight of the mass, which gives

$$234 \times 27\cdot 57 = 6451 \text{ lbs.}$$

The formula is $R^2\ l\ c$, when

R = the revolutions per minute;
l = the length of the crank in decimals of a foot; and
c = the coefficient of centrifugal force.

The connecting rod is 48in., or 6 cranks, in length. This affects the initial acceleration, making this to be on the dead centre farthest from the crank 7,526 lbs., and on the dead centre nearest to the crank 5,376lb., a difference of 40 per cent.

The area of the cyclinder is 98·2 square inches.

The area of the piston rod, $1\frac{3}{4}$ inches diameter, is 2·4 square inches, leaving area of cylinder at crank end 95·8 square inches.

The initial accelerating forces are therefore as follows, viz.: at the end of the cylinder farthest from the crank 77 lbs., and at the end of the cylinder nearest to the crank 56 lbs., on the square inch of piston area.

The counterweight was after some trials fixed at 135 lbs. This leaves 99 lbs. of the reciprocating parts running unbalanced. It is found that this is not sufficient to disturb the stability of the engine, while on the other hand the counterweight is not so great as to exert an objectionable strain in the vertical direction.

The total weight of the engine is 6,445lbs. The engine and dynamo are mounted on a cast iron base plate, made, for convenience, in two parts, and bolted together.

The dimensions of this base plate are as follows:—Length 14ft., width 8ft. 9in., and its weight is 10,300lbs. The entire weight is is, therefore, as follows:—

Base plate	10,300lbs.
Dynamo	44,800 „
Engine	6,450 „
Total	61,550lbs.

Fig. 2 is a view of the dynamo and engine combined. [Our illustration of the dynamo and engine is taken from one of the combined machines as fixed in the Holborn Viaduct Station of the Edison Company in London, and represents the machine from a somewhat different point of view to that illustrated in the *Journal* of the Franklin Institute. A view of the machine will be found in *The Electrician*, Vol. VIII., p. 202, where also the details of the armature are illustrated and described.—Ed. *E.*]

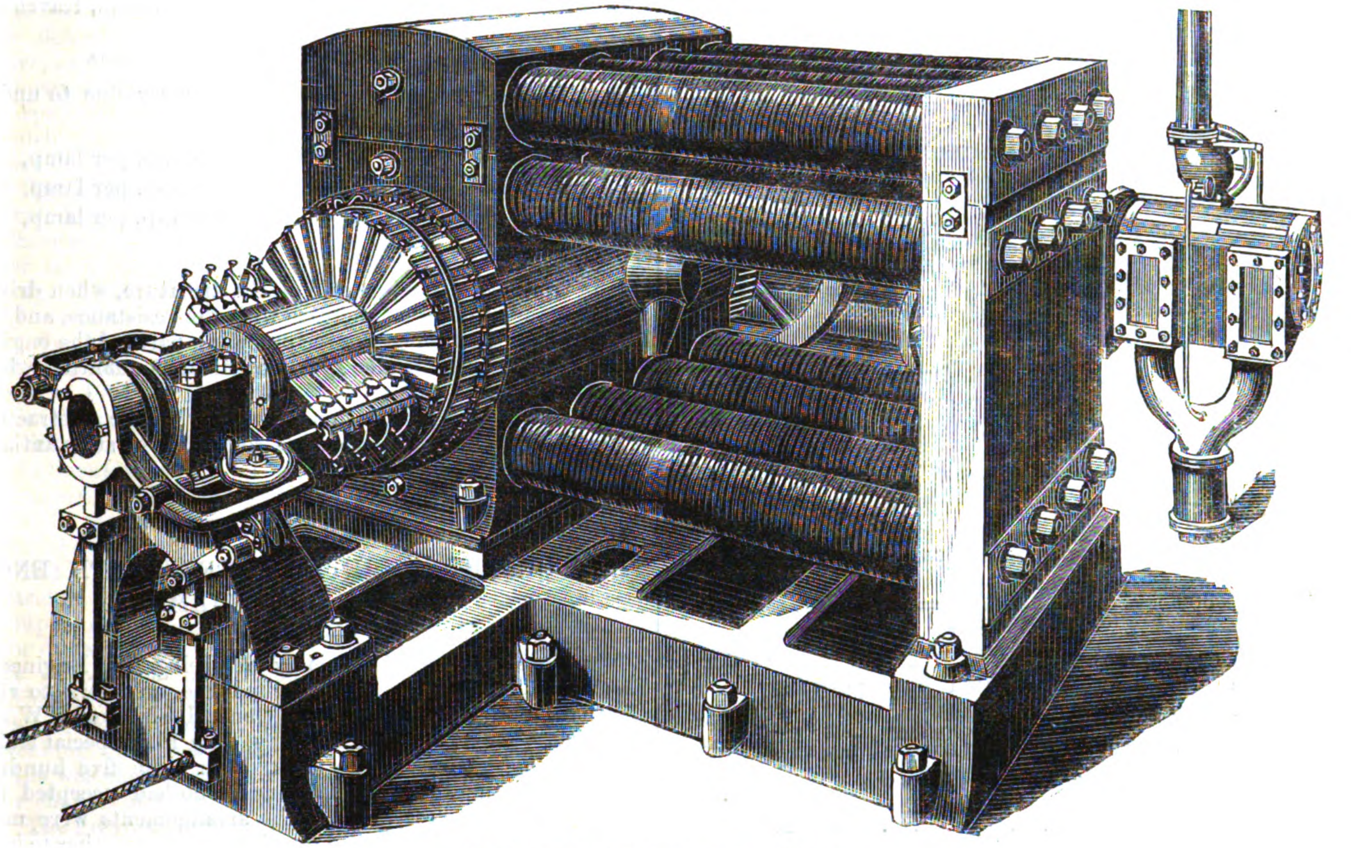

Fig. 2.—Edison's New Dynamo at Holborn.

The last and most careful test of one of these dynamos gives the following results, as shown by the indicator diagrams, which are here reproduced half size; scale 80lb. to the inch. [A note is here appended by the editor of the *Journal* to the following effect:—"As many persons might doubt about these diagrams having been really taken from any engine and by any indicator at this speed, we have examined the originals taken by a Tabor indicator, and can vouch for their accuracy." We may add that the diagrams were given full size in the *Journal*.—Ed. *E.*]

The lamps used in all the trials were of the older construction, of which $8\frac{1}{2}$ lamps, at 16 candle-power incandescence, require 1 horse-power of electrical energy. Since these were placed for experimental uses improvements in the lamp have increased their economy, so that 1 horse-power is sufficient to maintain fully 10 of the present lamps at 16 candle-power incandescence.

Digitized by Google

Diagram No. 1 shows the friction of engine and dynamo at 350 revolutions per minute, requiring 13·63 h.-p.

Diagram No. 2 shows the resistance with the magnet circuit on = ... 19·17 h.-p.

Field 5·78 ohms, 103 volts.

The increased resistance due to the magnets was 5·54 h.-p.

Of this, the calculated energy developed in the

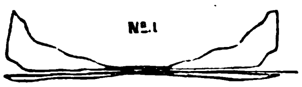
magnets was $\frac{103^2 \times 44{\cdot}3}{5{\cdot}78 \times 33{,}000}$ = ... 2·46 h.-p.

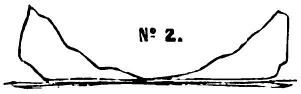
Leaving energy to be accounted for by local currents in iron core of armature, and in armature bars .... 3·08 h.-p.

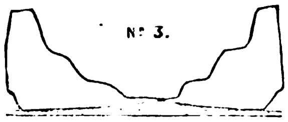
Diagram No. 3 shows the work done in maintaining 300 lamps.

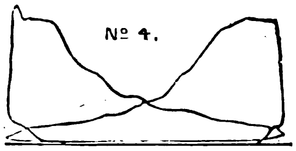
These, in the ratio of $8\frac{1}{2}$ to 10, were equal to 353 lamps of the present construction. The pressure was maintained also at 102 volts, representing 25 candle-power in place of 98 volts, representing 16 candle-power incandescence, which requires the number of lamps to be increased in the ratio of 102^2 to 98^2, or to 382 lamps.

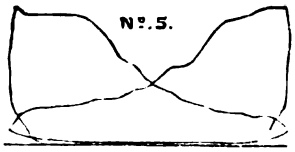
The pressure at the armature was 104 volts, showing a loss in the conductor of 2 volts, which would increase the number of lamps as 104:102.*











The total correction is, therefore, as follows:—

$$300 \times \frac{10}{8{\cdot}5} \times \frac{102^2}{98^2} \times \frac{104}{102} = 389 \text{ lamps.}$$

The power exerted was .... 60·6 h.-p. which gives to the indicated horse-power $389 \div 60{\cdot}6 = 6{\cdot}42$ lamps.

The magnet circuit had now a resistance of 5·28 ohms, with 104 volts pressure, representing

$$\frac{104^2 \times 44{\cdot}3}{5{\cdot}28 \times 33{,}000} = \; . \; . \; . \; . \; . \; . \; 2{\cdot}75 \text{ h.-p.}$$

Substituting this in place of 2·46 h.-p. in the first trial, we have 19·46 h.-p., which, deducted from 60·6 h.-p., leaves net 41·14 h.-p. This gives $389 \div 41{\cdot}14 = 9{\cdot}45$ lamps per h.-p.

Diagram No. 4 shows the work done in maintaining 700 lamps. The pressure at the lamps was maintained, as in the preceding trial, at 102 volts, which required at the armature a pressure of 105 volts. The total correction in this case is, therefore,

$$700 \times \frac{10}{8{\cdot}5} \times \frac{102^2}{98^2} \times \frac{105}{102} = 919 \text{ lamps.}$$

The power exerted was . . . . . 115·83 h.-p.

giving to the indicated horse-power,

$$919 \div 115{\cdot}83 = 7{\cdot}93 \text{ lamps.}$$

The resistance of the magnet circuit was now 4·78 ohms., with 105 volts pressure, representing $\frac{105^2 \times 44{\cdot}3}{4{\cdot}78 \times 33{,}000} = 3{\cdot}1$ h.-p.

Substituting this in place of 2·46 h.-p. in the first trial, we have 19·81, which, deducted from 115·83 h.-p., leaves net 96·02 h.-p. This gives $919 \div 96{\cdot}02 = 9{\cdot}57$ lamps per h.-p.

Diagram No. 5 shows the work done in maintaining 1050 lamps. The pressure at the lamps was maintained in this trial at only 99 volts, but this required at the armature a pressure of 108 volts, showing a loss of 9 volts in conduction. The total correction in this case is thus

$$1050 \times \frac{10}{8{\cdot}5} \times \frac{99^2}{98^2} \times \frac{108}{99} = 1375 \text{ lamps.}$$

The power was .... 168·4 h.-p., giving to the indicated horse-power

$$1375 \div 168{\cdot}4 = 8{\cdot}16 \text{ lamps.}$$

The resistance of the magnet circuit was now 3·28 ohms, with 108 volts pressure, representing

$$\frac{108^2 \times 44{\cdot}3}{3{\cdot}28 \times 23{,}000} = 4{\cdot}77 \text{ h.-p.}$$

Substituting this in place of 2·45 h.-p. in the first trial, we have 21·48 h.-p., which, deducted from 168·4 h.-p., leaves net 146·92 h.-p.

This gives 1375 + 146·92 = 9·36 lamps per h.-p.

It will be seen that the losses of efficiency due to undiscovered resistances are only

In the first case......... $10 - 9{\cdot}45 = {\cdot}55$ h.-p. per lamp,
In the second case ... $10 - 9{\cdot}57 = {\cdot}43$ h.-p. per lamp, and
In the third place...... $10 - 9{\cdot}36 = {\cdot}64$ h.-p. per lamp,

Averaging 5·4 per cent.

The friction in the journals of the armature, when driven in this manner, does not increase with the resistance, and, on account of the action of the reciprocating parts of the engine, that in its bearings is also nearly a constant quantity, whatever the load may be.

The above figures show this very clearly, the subtraction of the friction diagram in each case exhibiting substantially the same net power per lamp.

* The conductors were insufficient, occasioning a loss, that increased with the increase in the number of lamps.

VISIT OF THE SOCIETY OF TELEGRAPH ENGINEERS TO CHATHAM.

The President of the Society of Telegraph Engineers, Lieut.-Colonel Webber, R.E., invited the members to visit Chatham, under permission from General Sir Evelyn Wood. The visit was arranged for Tuesday, July 11. Special trains from Holborn and Victoria took down some five hundred members of the society and friends, who had accepted the invitation to the reception. The arrangements were most admirable, and had it pleased the clerk of the weather to have been a little more propitious, a pleasanter visit could hardly have been made. Even with the disadvantage of a few showers the enjoyment seemed complete.

It may interest those who were unable to be present to have a brief description of what took place. Ample provision of carriages had been made, so that the visitors could drive from the station to the Brompton Barracks, where the reception was held. The rain held off during the drive. On reaching the barracks the guests were divided into parties, each party having an officer as guide. Luncheon was provided, and while one half the party did justice to the viands, the other half was entertained by a lecture on Submarine Mining, delivered by Major Armstrong, R.E., in the lecture theatre. The lecturer briefly described the work of the School, and referred to adverse criticism regarding lack of novelty in the exhibits at the late Exhibition at the Crystal Palace, pointing out that it would be injudicious to make known the novelties designed by their own officers. He admitted that they endeavoured to make themselves conver-

Digitized by Google

sant with progress in electrical science so far as information could be obtained, but it was hardly thought wise to publish abroad all the improvements adopted.

A short and graphic history of submarine mines and torpedo work was given, illustrating the recent development of this mode of attack and defence. It was used a little in the Crimean war, but it was not till the American Civil War that any great attention was paid to the system. From then till now it has been constantly and carefully studied. Not only England, but other nations, have erected factories and carried out experiments, and this at considerable risk, for the dangers are great, and accidents frequent. Thus the whole of the Argentine works were destroyed, and not a man within left alive to tell the tale. So again at the nucleous works of the Indian Government, and so on. Thanks, however, to Professor Abel, a past president of the society, the use of gun cotton has become comparatively free from danger, while its manufacture has been carried to a state of great perfection.

A certain number of men (469), aided by some militia officers, are told off for the defence of our military harbours.

The submarine mines used are either permanent or temporary. The former are very expensive, because of the substantial manner in which they must be made if they are not to deteriorate as time passes; the latter are less expensive, and are practically used. Of course, the object of the apparatus is to destroy hostile vessels. The system includes torpedoes, or active apparatus and mines, or passive, inasmuch as the latter are fixed, while the former are caused to move.

The mines are of two kinds, according to the manner of exploding them, which may be mechanical or electrical. Those exploded by mechanical means were described as bad for friend and foe, while the others were dangerous to foes only. Those exploded by electric methods might be exploded by contact, or by (observation) a man completing contact at the right moment. The contact mines contain 100lb. of gun cotton, the observation mines 500lb, the latter being laid in 40 to 50 fathoms of water, and guarding a space of 100ft. diameter.

Several experiments were shown. Thus, 1oz. of gun cotton was burnt to show its harmlessness when not fired by an explosive. An ordinary fuse was exploded, to give some idea of the sound arising. The mechanism of a contact mine was shown, &c.

After the lecture the visitors were taken through the various departments—such as the laboratory, the photographic and the lithographic rooms, the experimental rooms for dynamos, electric light, &c. The workshops were visited, as well as the model shed. The way of making temporary bridges for men, and for men and light artillery, was shown, as was the making of gabions and fascines. Close by the working detachment, the use of gun cotton for destroying rails was shown—a double-headed steel rail being broken up by charges of 11oz. of gun cotton.

The greatest interest was shown in the illustration of the use of larger quantities of explosives. For this purpose a submarine mine, containing 100lb. of gun cotton, was exploded by the contact method. The visitors could plainly see the buoy with which the little steam launch was to make contact, and when the contact was made saw the water rise geyser-like the height of 150ft. or 200ft. Of course the mine was placed at a safe distance from the point of contact. Then a strong stockade of baulks of timber was destroyed by an explosion of gun cotton, the charge being fixed and fired by a firing party, detailed for the work as in active warfare. The last experiment of this kind was the explosion of a mine of 1,000lb of powder, and words cannot describe the grand spectacle of the mass of earth rising gently cloudwards, like a huge fountain, and gradually sinking down again. A procession of steam sappers, then tea and music, concluded the entertainments of the day. We heartily congratulate Col. Webber and his colleagues on the success which attended all their experiments, and we think the members who visited Chatham will look back upon the day as one of the most interesting and enjoyable of the year.

ELECTRIC LIGHTING FOR CAMBERWELL.

Revised Specification.

The roads proposed to be lighted are as follow:—Camberwell-road, from parish boundary, Boundary-lane to Camberwell-green; Church-street, Camberwell; Peckham-road, High-street, Peckham, and Queen's-road, Peckham, to parish boundary at Pomeroy-street.

The conditions are as follow:—The tenderers are to state the situations proposed for the electric lamps, the situations of the conducting wires, and the gas lamps which will not be required whilst the electric light is in operation. The tenderers are especially directed to consider in placing the proposed electric lights, to keep in view the lighting afforded by the present lamps at the corners of the collateral streets, so that such collateral streets in the reduction of the number of the present gas lamps may suffer as little as possible. Should tenders be accepted, the places named are to be lighted nightly, from sunset to sunrise, for 12 months, commencing on the 2nd October next, and terminating on the 1st October, 1883, with power to determine the same as hereinafter provided. The contractor shall also, on the requisition of the surveyor, light the said lamps on occasions of dense fogs during the day. The vestry, in the event of not being satisfied with the performance of the contract and the operations thereunder, reserves the power of determining the contract at any time after the expiration of three months, on giving the contractor four weeks' notice in writing.

The contractor must supply the motive power, electrical machinery, conductors, lamps, carbons, attendance, and everything requisite for lighting the roads during the contract period. This plant will be the property of the contractor, and at the expiration of the contract will have to be removed by him, at his cost. All paving and other property of the vestry disturbed by the contractor are also to be reinstated by him at his cost. The work of fixing conductors, fitting up machinery, lamps, &c., may be commenced within a fortnight after the tender has been accepted and the contract duly signed; and the whole system must be complete and ready for lighting on or before the 2nd October next, on the evening of which day the lighting must commence. The existing lamp columns may be made use of for erecting the electric lamps, or the contractor may erect special columns or posts for that purpose, as may appear to him best. In executing these works, the lamps, apparatus, and means of public lighting by gas are in no way to be disturbed.

Suitable sites for placing the engines and electrical machines must be obtained by the contractor, but it is clearly to be understood that no consent will be given for the appropriation of any part of the public way which is likely in the least to interfere with public or local convenience; the contractor therefore must provide in his estimate for the cost of acquiring such suitable sites for the stations. The contractor must enclose by a suitable shed or building the engines and machinery, provide the requisite foundations for the engines, and all that is requisite for the protection of the machines and motive power. Where pavements are disturbed the contractors will be charged with the re-instatement at the schedule of prices, as follow:—Granite pitching (including concrete), 2s. per yard super.; macadam roadway, 1s. 6d. per yard super.; footway paving, 2d. per foot super.; kerbing, 2d. per foot run. The contractor must be responsible for, and hold the vestry harmless on account of any accident or damage that may arise from imperfect lighting of the public ways, or from laying or fixing conductors and engines, or from any cause whatever which may arise from the carrying out of his contract for electrical lighting. Payments will be made quarterly, in equal instalments upon the total contract price, upon the surveyor's certificate that the contract has been duly fulfilled, but the final payment will not be made until he has certified that the machines, structures, and everything else have been removed, and the pavement made good. The tenders are to be accompanied by an accurate description of the whole system to be employed for the electric lighting. Tenders are to be addressed to the General Purposes Committee, Vestry Hall, Camberwell, before the 17th July, at 4 o'clock, and no tender will be received after that time.

A note is attached to the specification stating that subject to the terms specified therein as between the vestry and the contractor, the contractor shall be at liberty to make such agreements as he may see fit at his own risk for the supply of electric lights to the traders and residents upon the lines of route. Mr. J. C. Reynolds, is surveyor to the vestry, and further information can be obtained from him at the Vestry Hall, Peckham-road, S.E.

New Company.—The Brush Electric Light Company of Ireland has been registered with a capital of £250,000.

NOMENCLATURE AND NOTATION.

We have from time to time called attention to the diversity which exists in the names and formulæ generally used in electrical science. Not long ago it was suggested that the Society of Telegraph Engineers should appoint a committee to deal with the matter, but the suggestion was not well received. New books are being continually written and published in which agreement in notation and nomenclature would be of service to the student, but such agreement is looked for in vain. We still believe that the Society of Telegraph Engineers is the proper body to move in this question; and we may point the Council to the precedent of the Institute of Actuaries, a small society comparatively, but one that has, we believe, done more for the profession it represents than any other society existing. A few years ago the notation employed by writers on insurance subjects was as diverse as that used now by writers on electrical subjects. A committee of the Institute considered the question, and a system of notation was drawn up and printed. The system will be found in the Institute Life Tables. The readers of papers before the Institute, and the writers in its *Journal* have to conform to the notation adopted, and it is difficult to find in this country or abroad any work of importance which does not use the system. The Institute "Text Book" just published will assist still further in perpetuating the system adopted. Could not the Society of Telegraph Engineers go and do likewise? The authority of a committee of the society deciding on a notation to be adopted would soon bear fruit. What we have said of notation applies quite as strongly to the question of nomenclature. Middle-aged electricians have had to change the nomenclature half a dozen times probably during the period of active life, and it seems likely, unless a decided stand is made, that the younger generation will also be continually changing. The article of Mr. Phillips, which we print in another column, has some bearing on this subject. It shows the delightful confusion of notation and nomenclature, as will also be known to the reader of recently published works. French and English measurements are given in books and papers indiscriminately. Letters are used in two consecutive pages to mean two different things, different letters are used in different books to mean the same thing. Thus, in the simple formula to illustrate Ohm's law, we get in the translation of M. Hospitalier's book $I = \frac{E}{R}$, while in Clerk Maxwell's the formula reads $C = \frac{E}{R}$, in the one case I having the signification of C in the other. In a book used by students preparing for the London University examination, we find C on one page used to signify "current," on the next to signify "capacity."

We have always been in favour of a notation and a nomenclature that to a certain extent explains itself. Thus, we prefer foot-pound-seconds, to centimetre-gramme-seconds, or metre-gramme seconds. The foot is a length known to every boy from continued observation, as is also the pound in weight, while the length centimetre or metre is known merely in the abstract, never being seen in the lower grade schools, home, or shop. The workmen in our factories, or the workmen who install the electric light, are not collegians; their education has not brought them into contact with the refined scientific methods adopted in these centres of learning. Ask a workman in any factory such a question as, What is a dyne?, and you will obtain a satisfactory reply in, perhaps, one out of a million cases. Yet the "dyne" is not so very new a term, and might have been expected to have been extensively adopted if we consider that it is a term used in Glasgow University. We think the term foot-pound is used so extensively because every one can understand it; whilst the terms which have been suggested or are used as substitutes have not this advantage.

We would urge the Council of the Society of Telegraph Engineers to reconsider whether this is not a subject that can be dealt with satisfactorily and advantageously by a committee appointed for such a purpose. If the society still feels disinclined to undertake the work it will be necessary for some other society to do it. The society should, however, look upon itself as *the* representative body, and not permit any other society to trespass more than has already been done upon its prerogative.

THE TELEGRAPH AND THE BOMBARDMENT OF ALEXANDRIA.

Electric lights of great power were successfully employed on board the "Alexandra," and other war ships before Alexandria, for the purpose of searching the harbour and descrying the operations carried on in the forts during the night-time. The wisdom of the preparations made by the Eastern Telegraph Company for the eventualities of war have been fully demonstrated. For some time past the

Digitized by Google

cable has been buoyed a few miles distant from the harbour ready to be picked up and worked at any moment. On Sunday the clerks who had been stationed on one of the war vessels near shore were transferred to the safer position on the "Chiltern," from which post communication with Europe was speedily established. Between her and the Fleet intercourse was then kept up by despatch boats. All commercial messages for Alexandria, however, were temporarily stopped. On Monday the "Chiltern" picked up the Cyprus cable, leaving the Malta cable on board H.M.S. "Helicon." The work of grappling was carried out in a most efficient manner, according to *The Times* correspondent, who says: "The 'Chiltern' signalled at seven o'clock that she had grappled the Cyprus cable. She will next splice it on to the cable which is now attached to the 'Helicon.' The 'Chiltern' is lying about three miles to the westward of the 'Helicon,' and will, perhaps, join the cable before daylight. The 'Helicon' will then proceed to the squadron lying off the forts, to take orders and repeat signals. The fact that the cable was picked up so promptly has given much satisfaction. From the time the 'Chiltern' left her anchorage in the harbour to the time the cable was grappled barely two hours elapsed. Communication was resumed immediately on the cable being got on board." On Tuesday the Company officially notified that their offices at Alexandria and Suez were temporarily closed, and that messages could only be accepted at the sender's risk, as their delivery may not be possible at present. Delay was also to be expected on telegrams for Aden, India, and the South African Stations. During the bombardment of the forts on Tuesday, the "Chiltern" continued moored about four miles distant, having on board the cables communicating with Malta and Cyprus. From this ship the Admiral's secretary continued to transmit intelligence to the Government in London throughout the day and evening. This was kept up with such frequency and speed that, practically, the Ministers may be said to have been spectators of the fray. The daily Press speak in high terms of the arrangements made by the Eastern Telegraph Company to meet these contingencies of war, and especially of the admirable manner in which, under circumstances of the greatest difficulty, the telegraphic service between Alexandria and London has been maintained. "It deserves to be mentioned," says the *Standard* of Wednesday, "that the telegram which we published in our second edition yesterday morning, announcing the commencement of the bombardment, was despatched from Her Majesty's ship 'Invincible' at forty minutes past seven a.m., and was received in London at five minutes past six a.m. (the difference in the time between Alexandria and London being as nearly as may be two hours), so that the message reached this office within about thirty-five minutes from the time it was despatched from Alexandria. The verbal accuracy, too, with which the messages are transmitted deserves the highest praise." *The Times* correspondent also speaks in the highest terms of the company's staff. He says:—"Nothing can exceed the extreme courtesy and attention which have been bestowed upon the public by this hard-working staff, both here (Alexandria) and in Cairo, under very trying circumstances." Wednesday morning's London papers published accounts of the engagement as witnessed from the "Chiltern," and telegraphed almost hourly to the directors of the Eastern Telegraph Company by their agents on board ship. Due precautions, we are glad to notice, are being taken for the protection of the "Chiltern" and her valuable charge. Admiral Seymour has ordered a war ship to cruise round her during the night-time. Up to Thursday morning communication was kept up by way of the "Chiltern," intercourse between it and the Fleet being maintained by means of maritime signalling, the electric light serving this purpose by night. At the time of our going to press news reaches us that the telegraph ship has been ordered inshore, the town of Alexandra having been evacuated by the Egyptian troops, in order to be closer to the Admiral. The Malta and Cyprus cables were, therefore, being spliced, and interruption of communication was to be expected for several hours. Sad news also reaches us that a young Frenchman, named Ternant, one of the *employés* of the Eastern Telegraph Company, who had preferred to remain on shore with his friends, instead of coming off with the rest of the staff, is among the victims of Wednesday night's massacre.

A PRACTICAL STUDY OF ELECTRICAL UNITS.

BY SAMUEL E. PHILLIPS.

This subject, like most others, admits of a double aspect of study, one of simple concreteness, where definite values are easily understood; the other of vast abstractions, where very indefinite values are the subjects of profound disputation.

One is strictly comparable to the simple problem by which a tradesman has to understand his weights and measures, as the other is to a difficult research into the deep origins of history and philosophy.

Any student desirous of ascertaining the simple or concrete facts of chemical, optical, or acoustic science would find that there is no book in existence to supply the desideratum, and precisely thus it is with electricity.

Confining ourselves to one aspect, we offer the following definitions:—

(1.) The unit of E.M.F., or potential, is a *volt*, which in concrete terms is approximatively equal to the force of one Daniell cell (a perfect Daniell cell being 1·079 of the theoretical volt); *potential* in electricity is in every way comparable to *pressure* in water.

(2). The unit of current quantity is a *veber*, or *ampere*. We speak of a current of so many pints or gallons of water *per second*, so in electricity a *veber* or *ampere* is that quantity which liberates ·000,158 grain of hydrogen per second, or does other equivalent chemical work. This is equal to one grain in 6,338 seconds. It is well to bear in mind this additional *time* unit, because it leads us to the truth and simplicity of Nature's units. Thus a veber or ampere current in unit time liberates a *grain-equivalent* of any element—that is, hydrogen 1, zinc 32·5, copper 31·7, silver 108, &c., &c. For practical purposes it may be worth remembering that this means 18·5 grains of zinc per hour.

(3.) The unit of static quantity is a *farad*, or that quantity which, if discharged through one ohm in one second, would give a veber current. Some prefer to regard it as an unit of *capacity*, referring to the vessel rather than to its contents, where one volt of force may charge a given condenser with one farad of quantity. As the veber current necessarily implies time, so the static farad equally implies potential, because two volts would charge the same condensor with a double quantity.

(4) The unit of resistance is an *ohm*, which is concretely represented by 129 yards of pure copper $\frac{1}{16}$in. diameter ($=62\frac{1}{2}$ mils., or ·0625 in.), offering a resistance of 1 ohm. These different quantities are so related that 1 volt, through 1 ohm, gives a *veber* current during 1 second, $\frac{E}{R}=C$.

Such are the principal units, and by their aid the most useful equations can be formed. It is necessary, however, to combine their use with some of the principal physical units, and, writing from the point of view of a butcher or grocer electrician, I would lament the scholastic confusion involved in so many different units.

Representing E.M.F. or potential by E, current by C, re-

Digitized by Google

sistance by R, heat by H, and work by W, &c., where each writer uses different symbols, and where the term "intensity" is used to express relations of *pure* quantity, we may note the following useful equations, $\frac{\text{E in volts}}{\text{R in ohms}} = \text{C in vebers}$, which simply means that the amount of current is *directly* as the potential, and *inversely* as the resistance offered in the circuit.

The total energy of a circuit expressed in heat or work units is (*a*) 1 volt × 1 veber = ·000955 "pound Fahrenheit" units of heat per second, or (*b*) 1^2 vebers × 1 ohm = ·737335 "foot pounds" of work per second; or multiplying these unit values by 6338 seconds, we have 6·053 units of heat, or 4673 foot pounds of work for the time of one grain equivalent, or in still further generality we may state the same thing thus :—

Volts × vebers × ·000955 = units of heat per second, or, the square of vebers × ohms × ·737335 = units of work per second; so that, in English terms, 6·053 heat units when converted into work = 4,673 foot-pounds; or, to heat 1lb. of water 1° F. requires an expenditure of energy equal to 772 foot-pounds. Or, to still further elucidate these relations, we may say,

	Vebers. Ohm.		
If in (*b*) case	$1^2 \times 1$	= ·737335 foot-pounds, then	
	$8^2 \times 8{\cdot}6$	= 550 foot-pounds per sec.	= 1 H.-P.
or (*a*),	8 × 93·25 volts ÷ 746		= 1 H.-P.

As the same principles apply equally to the whole circuit or to any part thereof, we give another illustration of (*a*) from a recent research of Mr. Jamieson upon a No. 6 Swan lamp under varied conditions. Measuring the quantity of current passing (the force or intensity of a current in no way affects a galvanometer, which measures quantity only), and otherwise, the force or potential at the two lamp terminals, we have (*a*) = the heat expended in the lamp, or (*a*) ÷ 746 = the H.-P. of energy involved in that part of the circuit.

We cite four cases from an extended table :—

	Volts.		Amperes.		Amperes of 1 Volt.		Heat Units per Ampere.		Total Heat Units.		
A	14	×	·23	=	3·92		—		—		Dull red heat.
B	27·5	×	·66	=	18·15		—		—		Bright red heat.
C	41·7	×	1·13	=	47·12	×	·000955	=	·45	=	4 candles, &c.
{ D	63·3	×	1·9	=	120·27	×	,,	=	1·148	=	50 candles, &c.
{ or	33·33	×	$1{\cdot}9^2$	=	120·27	÷	746	=	·161 h.p.		

In this endeavour towards an uniform consistency we have violated a fashionable empiricism, where English and French units are mixed up in perplexing confusion.

Now, before entering upon other than English units, I would express indebtedness to Mr. Sprague, whose clear intellect and original intrepidity are exceedingly refreshing. It may be from inferior powers that I cannot follow him in all particulars, but speaking again of the fashionable "intensity," he says, p. 148, referring to "*current*-quantity symbolised by C, this is commonly called 'intensity of current,' and is symbolised by I.

"This mongrel term, derived from the translators of the French phrase '*intensité de courant*' (strength or amount of current), leads to great confusion of ideas, because 'intensity' has in the earlier English books a distinct meaning, which corresponds to '*tension*,' and has no connection with *current* or *quantity*."

Of the French metric system, he observes, "It is none the less arbitrary, the only advantage lies in the decimal system simplifying calculations."

One word as to the heat or work being as the square of the current. This should be clearly grasped, not as a technicality, but as an inherent law in the nature of things generally. A given head of water, or hydraulic *potential*, will cause a certain flow of water through a pipe of given resistance, and apart from friction we may suppose it operating a paddle wheel with a given velocity. A double height of column, or double pressure would, through an equal resistance, give a double quantity in the same time, with double force, and therefore drive the wheel with fourfold energy or velocity.

It is precisely thus with electricity, where the principle admits of still clearer illustration :

$$\frac{1\text{ volt}}{1\text{ ohm}} = 1\text{ veber} = 4{,}673\text{ foot-pounds in }6{,}338\text{ seconds,}$$

$$\frac{2\text{ volts}}{1\text{ ohm}} = 2\text{ vebers} = 18{,}692 \quad \text{,,} \quad \text{,,}$$

Here the currents are related as 1 to 2, and the total energies as 1 to 4. One would charge a given condenser with 1 of quantity, say 1 farad of one-fold force; the other would charge the same condenser with double quantity and four-fold force; the opposing surfaces would each have a double quantity of double tension, and, therefore, the attractive force would be fourfold.

Now, let us see that a double current really involves a fourfold cost or consumption of zinc :

One Daniell cell with a resistance of 1 *ohm.*

$$\frac{1\ \text{E}}{1\ \text{R}} = 1\text{ veber} = 4{,}673\text{ foot-pounds} = 32{\cdot}5\text{ grains of zinc,}$$
consumed in 6,338 seconds.

Two larger cells of half internal resistance.

$$\frac{2\ \text{E}}{1\ \text{R}} = 2\text{ vebers} = 18{,}692\text{ foot-pounds} = 130\text{ grains of zinc,}$$
consumed in 6,338 seconds.

Each cell would work under a double tension, and therefore give a double current and double consumption of zinc *in each cell*, making 130 grains instead of 32·5.

Now why have we deferred all mention hitherto of the French *coulomb?* Because it seems an *unnecessary* complication. We speak of a current of so many gallons of water per second, and this, × by the time in seconds, must give any desired totality of *gallons*.

If we similarly × the vebers by the time in seconds, the result must be *vebers*, or *amperes*, but these are now called *coulombs*.

In our treatment of the Jamieson experiments, we similarly × the volts by amperes, which must give a total of *one volt amperes*. Nor would it help matters to call these by a new-fangled name. Any equation must be valuable or appropriate in proportion as it enables a student to understand the essential *rationale* of the process. Gallons × must be gallons, just as amperes × must be *amperes*, but call either of these by quite different name, and the student is compelled to think of the unmeaning name rather than of the essential reality. Every derivative value or useful application derived from *coulombs* must necessarily spring from, and arise out of, *amperes*.

An *ampere* liberates ·000158 grains of H per second, &c., and in every particular does precisely what a *coulomb* does.

It may be, and indeed is, alleged that an ampere is an ampere per second, and a *coulomb* is an abstract *ampere* apart from time, but the definition is equivocal, and proceeds from a mistaken basis. Gallons *per second*, as *applied to current*, are none the less gallons; and amperes per second, as applied to current, are none the less *amperes*. The time function is an adjunct, and not a necessary or invariable constituent.

The English calory or heat unit	= 1lb. of water raised 1° F.	= 772 ft.-lb.
sometimes the unit employed	= 1lb. of water raised 1° C.	= 1389·6 ft.-lb.
The French calorie	= 1 gr. of water raised 1° C.	= ·425 gr. met.
or more commonly	= 1 klg. of water raised 1° C.	= 425 kilog.

As the English calory is equal in mechanical energy to lifting 772 pounds one foot high, so the French calorie (in the latter case) is equal to lifting 425 kilogrammes one metre high :—

A kilogramme = 2·2lb. (2·2046215); the metre = 39·37 inches (3·2808992ft.)
The kilogramme C° unit = 3072·75 foot-pounds.

The following comparisons may be useful in further elucidating these relations :—

Volts.		Amperes.		Volt Amperos.				Kilog.-meters.				Foot-pounds.	
88·33	×	·646	=	57·08	÷	9·81	=	5·819	×	7·23	=	42·07	(*a*)
								H.-P.					
88·33	×	·646	=	57·08	÷	746	=	·076	×	550	=	42·07	(*b*)
								Total heat units.					
88·33	×	·646	=	57·08	×	·000955	=	·0545	×	772	=	42·07	(*c*)
88·33	×	·646	=	57·08	×	·2405	=	13·727	×	3·073	=	42·18	(*d*)
88·33	×	·646	=	57·08	×	·737335	=					42·07	(*e*)

Digitized by Google

(*a*) 1 kilogrammetre = 7·23 foot-pounds because 1 kilo. × 1 metre = 7·23.

(*b*) As all these values imply *per second*, so 550 is the 60th part of 33,000 foot-pounds per minute.

(*c*) As the English heat unit is worth 772 foot-pounds, so the total heat units × by 772 = total foot-pounds.

(*d*) 1 volt through 1 ohm in one second = one ampere or a volt ampere; and one ampere of current generates ·000955 English units of heat, or ·2405 French gram. C° unit where each unit is equivalent to 3·073 foot-pounds.

(*e*) The volt ampere is worth ·737335 foot-pounds, therefore 57·08 amperes = 42·08 foot-pounds. It only remains to add that most of these values must be taken as approximative, especially so in regard to their decimal parts. We have followed Mr. Sprague and most books in liberating ·000158 grains of H, per *veber* of current; but there are other determinations, and some prefer to consider that value as ·000162.

ELECTRICAL ACCUMULATORS OR SECONDARY BATTERIES.*

BY PROFESSOR OLIVER J. LODGE, D.SC.

No. V.

(CONTINUED FROM PAGE 158.)

I now proceed to the complete investigation of the most advantageous conditions when charging a set of similar secondary batteries with a shunt dynamo driven at a constant speed:—

Let P be the horse-power actually applied to the driving of the dynamo when it is in full action, at the given speed, as determined by a dynamometer.

Let P^1 be the power required to drive the dynamo at the same speed when it is not allowed to produce any current whatever; that is, the power necessary to overcome the friction and the resistance of the air. So that $P - P^1$ is the whole horse-power available for electrical purposes, and of this some will be expended in heating the armature and field magnet wires.

Let A be the resistance of the armature wire in ohms.
B the resistance of the wire on the field magnets.
R the resistance of the leading wires conveying the current to the cells.
r the resistance of each of the cells.

Let N ($= n\,m$) be the number of cells being charged—arranged n tandem and m abreast.
e the maximum electromotive force in each cell opposing the charging current in volts.
c the current flowing through each cell in Ampères.
b the current flowing through the field magnets of the dynamo.
E the difference of potential between the terminals of the dynamo when it is in action charging the cells.

Of these quantities it is essential that E shall be greater than $n\,e$ if the cells are to be charged at all. If $n\,e$ is the greater they are slowly discharging themselves through the dynamo and are helping to turn it. The nearer $n\,e$ comes up to E the easier will it be for the engine to drive the dynamo, and as soon as $n\,e$ exceeds E it will begin to drive the engine instead of the engine driving it. If the engine strap is slipped the dynamo will go on turning at the expense of the now discharging battery in the same direction as when it was charging it.

The following relations hold among the above quantities:—

$$E = n\,e + n\,r\,c + m\,R\,c \quad (1)$$
$$E = B\,b \quad (2)$$
$$746\,(P - P^1) = E\,(m\,c + b) + A\,(m\,c + b)^2 \quad (3)$$
$$E + A\,(m\,c + b) = \Phi\,(b) \quad (4)$$

The last being a statement that the whole electromotive force generated by the revolving armature is a function of the current flowing round the field magnet; but what that function is depends upon the construction of the machine, and especially upon how near the iron of the magnets is to being saturated. If it is saturated the function is a constant; if it is nowhere near saturation, the function is simple proportion. It can be determined by experiment and plotted.

Of all the above quantities,

P^1 has a fixed value determined by the speed employed, and ascertainable by direct measurement.

e and r may also be taken as fixed and known quantities, for the size of the cell is a matter of convenience, and this determines r; while e is a function of the materials used in the cells, and for Planté or Faure it is about $2\frac{1}{2}$ volts.

R is easily measured, and can be made as small as convenient.

A and B are also easily measurable, and though not uncontrollable, must yet be considered fixed for a particular dynamo.

n and m are of course completely under control, and we have to determine what is the most economical ratio $n : m$. But at present they can be regarded as given quantities.

The remaining four of the above quantities, viz., c b, P, and E, are dependent variables, and are given in terms of the others by the preceding four equations.

The number of thermal units (water—gramme—degree—centigrade) produced every second is:—

At the bearings and in the air churned by the machine, $178\,P^1$;

in the armature $\frac{A}{4{\cdot}2}\,(m\,c + b)^2$;

in the field magnet $\frac{E^2}{4{\cdot}2\,B}$;

in the cells $\frac{1}{4{\cdot}2}\,N\,r\,c^2$;

in the leading wire $\frac{1}{4{\cdot}2}\,R\,m^2\,c^2$;

The energy utilised as chemical work is $N\,e\,c$.

What we want of course is to make this last term as great as possible in comparison with the preceding five terms. Now it must be obvious that the smaller P^1 and R can be got the better. It also appears from the second and third of the above terms that it is good to have A small and B large. But what about N? N appears as loss only in the fourth term, and as gain in the the sixth; hence it must be advantageous to make N large. But then N contains two factors, n and m; and the second of them appears squared in two of the above loss terms; hence, though it is good to have n as large as possible, it is quite a question how big m should be. We find, however, by a little calculation, that to make $N\,e\,c$ as large as possible, compared with the other terms, that is, to make the ratio of useful work to the waste a maximum, we must have—

$$\frac{m}{n} = \left(r + \frac{e}{c}\right)\left(\frac{A + B}{B^2\,(A + R) + 2\,A\,B\,R + R^2\,(A + B)}\right)^{\frac{1}{2}} \quad . \quad (5)$$

or since R and A are, in practice, small, compared with B, we may say that the best possible value of the ratio $m : n$ is very approximately

$$\frac{m}{n} = \frac{e + r\,c}{B\,c}\sqrt{\left(\frac{A + B}{A + R}\right)} \quad . \; . \; . \; . \quad (5^1)$$

We perceive, therefore, that the best value of m depends upon c. If the current flowing through each cell is very weak, a large number may be arranged abreast; but if c is pretty strong m must not be great. Now, the permissible value of c depends entirely upon the size of the cell, for it is the "intensity," or as some call it the "density," of current —that is the current per unit area of electrode—which is to be kept small. But though a very small current is economical, not only because it reduces the waste heat, but, more important still, because it allows the chemical changes to go on slowly and steadily without evolution of gas or secondary disturbances; yet in practice a charging current of only one ampere through large cells would be felt to be somewhat tedious, and an allowance of five amperes would still be very moderate.

I will therefore suppose that the actual value of c is deter-

* We reprint these excellent articles from the *Engineer*.

Digitized by Google

mined by practical convenience, and is measured by a galvanometer. Equation (5^1) fixes the best value of m in terms of n—but what is the best value of n? The equations indicate that the nearer $n\,e$ is to its maximum permissible value the better. The maximum value is

$$E_0 = \Phi\,(b_0) - A\,b_0 \qquad (6)$$

But if it is too near this value, not only will the charging be very slow, but, unless the engine is absolutely steady, there will be a risk of the cells sometimes helping to drive it. It need not be so very far short of this upper limit, however, for the current tapped through the outer circuit ($m\,c$) will not be usually great enough to reduce b much below its maximum value b_0, nor E much below E ; and so we may put pretty nearly

$$\begin{aligned} n\,e &< E_0 - A\ m\,c \\ &= Bb - A\ m\,c \end{aligned} \qquad (7)$$

Or putting in the best value of m from (5^1) we get

$$n = \frac{b\,B^2\sqrt{(A + R)}}{e\,B\sqrt{(A + R)} + (e + r\,c)\,A\sqrt{(A + B)}} \qquad (8)$$

The current through the field magnet which enters into this expression is not an absolute constant, even at a given speed, since it depends somewhat upon how much current is tapped off through the outer circuit—that is, upon $m\,c$. Nevertheless, if the wire on the magnet has a properly high resistance, it will be found that b is very nearly independent of $m\,c$, unless the latter is enormous. And as we have expressly said that $m\,c$ is not to be very great, we may regard the value of b at the given speed as nearly constant, and may measure it with a galvanometer.

Practically the value of n would be determined by adding to the series of cells until the current is brought down to the desired small value, taking care that the limit E is not too nearly approached, for fear that a diminution in the speed of the engine might cause it to fall below $n\,e$.

Observe that the greater n is the greater m may be too, so as to maintain the most economical ratio (5).

ELECTRIC LIGHTING FOR THE CITY.

According to a report recently presented to the City Commissioners of Sewers by their Streets Committee, the question of extending the electric light to the eastern portion of the City came before them so far back as the 22nd of March and 25th October, 1881, in the shape of memorials from the inhabitants of Leadenhall-street, Fenchurch-street, and Billiter-street, and from the Portsoken Ward Association. The matter again cropped up on the 7th February, 1882, and in the end the engineer, Mr. William Haywood, was instructed to prepare plans and conditions for "further experiments in electric lighting, not only in the east but also in the north and west of the City, and it was agreed to form four districts for the purpose of inviting tenders for such work." As most of our readers will remember, tenders were invited, and were to be sent in by the 12th May.

The districts to be lighted were as follow:—

District No. 1, comprising St. Martin's-le-Grand, Aldersgate-street, Long-lane (between Aldersgate-street and Smithfield), Smithfield, east side (between Long-lane and Giltspur-street), Giltspur-street, and Newgate-street.

District No. 2, comprising Cornhill, Bishopsgate-street (between Cornhill and Liverpool-street), Liverpool-street (between Bishopsgate-street and New Broad-street), New Broad-street, Old Broad-street, and Threadneedle-street (between Old Broad-street and the front of the Royal Exchange).

District No. 3, comprising Lombard-street, Fenchurch-street, Aldgate, Aldgate High-street, and Leadenhall-street, and

District No. 4, which is identical with the district lighted last year by Messrs. Siemens, and which comprises London Bridge, Queen-street (between Queen Victoria-street and Cheapside), Cheapside (between King-street and Poultry), King-street, Guildhall-yard, Poultry, Mansion House-street, Royal Exchange (open space in front of), King William-street, and Adelaide-place.

The following abstract of the tenders received, prepared by Mr. Haywood, shows the minimum and maximum cost of lighting by electricity as stated in such tenders, compared with the present cost of gas lighting:—

In District No. 1, the tenders varied from £2,190 to £5,750, as against £551 the present cost of gas.

In District No. 2, the tenders varied from £2,350 to £4,270, as against £363 for gas.

In District No. 3, the tenders varied from £2,470 to £3,800, as against £341 for gas.

In District No. 4 the tenders varied from £2,920 to £4,350, as against £612, the present cost of gas.

The report concludes as follows:—"Looking at the experiments which the commission have already carried out, and the great cost of extending the same, as shown by the offers now submitted, we are not prepared to recommend Your Honourable Court to proceed further in the matter at present; the more so as by the Bill now before Parliament, and draft amendments suggested by the Board of Trade, it is proposed to give power to the local authorities to supply electricity not only for public but for private purposes, or to acquire compulsorily the undertakings of other parties after fifteen years from the passing of the Act under which they may be empowered; and until Parliament has decided the principle upon which electric lighting generally shall be permitted we consider it undesirable to incur further expense beyond that to which the commission are already committed by the experiments now in operation."

This report and recommendation was adopted at a meeting of the Commissioners of Sewers held on the 20th of June.

On the next page we give an abstract of the various tenders sent in, as appended to the report.

Note.—The Electric Light Engineering Company make it a condition that they may be permitted to light private premises in the districts for which they tender. The Electric Light and Power Generator Company tender for No. 1 District only, and ask to supply lighting to private premises. Mr. James Fyfe, if permitted to light private premises, would make the charge for lighting the streets the same as the gas saved plus 20 per cent. This applies to both the Joel and Pilsen systems. The Hammond Electric Light and Power Supply Company will light all four districts for £3,000.

The following particulars refer to the kind of lamps to be used, mode of fixing same and conductors, &c. contained in the tenders for District No. 1:—

Mr. J. D. Cardew will use C. H. Long's patent lamps. The conductors will be of copper wire stranded together, properly insulated, and laid in cast-iron pipes beneath the footways and alongside the channels in the carriageways. The engine will be of 25 h.-p. semi-locomotive. The dynamo machines will be C. H. Long's patent, and placed in premises on the north side of Long-lane, near Hague-street.

The Electric Light Engineering Company will use A. A. Common's patent arc lamps, erected on the existing five-light columns, where available, elsewhere special columns to be erected. The conductors will be of copper wire, suspended from lamp to lamp, or fastened to points of houses, and crossing the roads either beneath the surface or at a height sufficient to clear the traffic. The engine will be 16 to 20 horse-power semi-portable.

The Electric Light and Power Generator Company will use Weston arc lamps, as now in use in Queen Victoria-street, fixed on special columns. The conductors will be of copper wire, properly insulated and laid in wooden troughs and iron pipes beneath the surface of streets. The engine will be 20 to 25 horse-power, and will drive four Weston dynamo machines, a smaller engine being kept in reserve. The station will be in a vault under the Central Meat Market.

Mr. A. L. Fyfe gives no description of the lamp he proposes to use, but will utilise the existing gas columns where

* Amended tender afterwards sent.

District No. 4.

The letters in the following table represent the contractors' names in the same order as they are given above, the columns being numbered as in the above table the better to identify them.

	1	2	3	4	5	6
	£	£	£			£
A	620	2986	3606	28	127	612 about
B	1850	1700	3550	30	136	—
C			No Tender.			
D	590	2900	3490	27	125	—
E	1139	2678	3817	33	139	—
F	1500	2850	4350	80	139	—
G	1200	2500	3700	40	137	—
H	720	2200	2920	36	all	—

practicable. The conductors, of which no description is given, will be placed underground, in cast iron pipes. No description of engine or dynamo is given. The station will be on the north side of Long-lane, near Hague-street.

Mr. James Fyfe in one tender proposes to use Pilsen arc lamps fixed on existing gas columns where available, or on new posts of similar pattern where required. The conductors will be of copper wire, insulated, and laid in cast iron pipes beneath the surface of the streets. The engine will be a 16 horse-power semi-portable, placed in a building at the Smithfield end of Giltspur-street.

Mr. James Fyfe in his second tender proposes to use Joel's semi-incandescent lamps fixed on existing gas columns. The wires to be laid as above. The engine to be a 30 horse-power semi-portable, fixed in same station as above.

The Hammond Electric Light and Power Supply Company propose to use Brush arc lamps, fixed on special columns 20ft. high. The conductors to be of copper wire, insulated, and laid in cast iron pipes beneath the surface of the streets. Semi-portable engines and Brush dynamo machines will be used. This company had not determined the site of their stations.

The Laing Electric Light and Power Company would use Laing arc lamps, fixed on special standards, and on existing gas columns where practicable. The conductors were not described, but would be laid underground on the Laing system. The engines were not described, but the dynamos would be on the Laing system. This company did not give the site of their station.

The particulars with reference to lamps, mode of laying conductors, &c., are the same for all four districts, the only difference being that the stations are different for each different district. We give the sites of these stations as mentioned by those tenderers who have fixed upon a station.

Thus, for District No. 2, Mr. Cardew's station would be No. 1, Swan-yard, Bishopsgate-street Without, Mr. A. L. Fyfe also taking this as his station. Mr. James Fyfe's station would be in White Hart-court, Bishopsgate-street Without.

For District No. 3, Messrs. Cardew's and A. L. Fyfe's station would be in Aldgate High-street, near Chequer-yard, and Mr. James Fyfe's in a building on the north side of Leadenhall-street, opposite Billiter-street.

For District No. 4, Messrs. Cardew's and A. L. Fyfe's station would be in Wheatsheaf-alley, near Fishmongers' Hall, and Mr. James Fyfe's in a warehouse in Swan-lane, Upper Thames-street.

CORRESPONDENCE.

THE INLAND TELEGRAPH SERVICE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: On behalf of the Telegraph Clerks' Association I thank you for the criticism you have deigned to award the sayings of our representatives.

Criticism is always useful—more especially so when coming from an organ so powerful as *The Electrician*, whose pungent opinions upon official matters are often suspected of being officially inspired—tending as it does to show us our own weak points, and, what is of equal importance (to us, at least), a knowledge of our opponents' strong ones.

As you so justly remark, the mere fact that the clerks have continued the agitation for twelve months after the promulgation of a scheme of revision, without considering expense or trouble, is alone sufficient proof that the scheme has failed to remedy the grievances acknowledged to have existed, either through its own imperfections, or through the "partial" character of its application.

That the Department has been able to stifle the agitation in the Central Office by means of indirect bribery and intimidation, thus enabling them to deal more arbitrarily with the rest of the service, is not, in my opinion, sufficient evidence to prove the scheme adequate. Before, however, making a definite statement upon that point, I think it would be advisable to briefly recapitulate what our exact grievances were in 1880, as set forth in our united petition of 31st January, 1881.

First.—Inadequate salaries, which, to a large extent, were due to the hindrance to promotion given by *classification*.

Second.—The mode of payment for overtime.

Third.—That no special payment was made for Sunday, Good Friday, and Christmas Day.

Fourth.—Insufficient annual leave of absence.

Fifth.—Inadequate subsistence allowance when employed away from home.

The question naturally follows, what has the scheme done to remove those grievances?

The second and fifth have, I admit, been to a large extent remedied, as also has the third, as far as regards Good Friday and Christmas Day; but, with respect to Sunday duty, we are on precisely the same footing as previously, Mr.

Digitized by Google

Fawcett's estimated value of the concession to the entire telegraph staff being only £300, which plainly shows that the grievance still exists. The fourth complaint, which the Postmaster-General considered of sufficient importance to promise further consideration, and even to warrant him in suggesting a remedy, has not been redressed. The first and most important grievance of all alone remains to be dealt with. In the course of your editorial remarks you say :—" If they (the Association) object to any sort of classification these delegates should say so, nay, they should have said so before the old classification was succeeded by an amended one of the same order."

I am afraid, sir, you have given but little attention to our various " *tavern innuendoes*," which the London and provincial press has so largely published, or else, for the moment, they had passed from your mind. That is identically what we have been petitioning and praying for from the beginning. We must not, however, be misunderstood. There are classifications and classifications ! We are fully aware that some kind of classification is necessary to divide the higher branches from the general body, such, for instance, as the Playfair scheme, but it is the classification of the general body we object to and ask the abolition of. It must be admitted that it is a farce to see two men sitting side by side, performing in every respect identically the same duties and equally well, the one a first-class clerk with 40s. per week, the other a second-class with probably 23s. per week, and equal length of service. It must necessarily create a spirit of dissatisfaction in the mind of the second-class clerk, that is, if he thinks at all, which is intensified when he remembers that *death* or some such remote contingent is the only means of his obtaining the position to which he naturally aspires, and his abilites and length of service entitle him. What is required, and what we believe is necessary for the welfare of the service, is abolition of such classification, and the opportunity given to all to commence at the minimum and rise by periodical increments—somewhat larger than are now given—to a fair maximum. Let there be but one class for the general body of telegraphists.

With respect to our new grievance, the " unjust and partial " application of the scheme, what, sir, would you naturally understand by amalgamation—that the two or more bodies amalgamated were made *one*, treated exactly alike, and enjoying the same priviliges ? Is this the case with our amalgamation ? We are certainly tacked on to the postal branch, but what do we find is the result of the application of the amalgamating scheme ? That, whilst the whole service of the postal clerks has been allowed for when fixing their positions and pay, the service of the telegraph clerks in the old companies, and, in many cases years of the time they have passed in the actual service of the Post Office is altogether ignored, although the Act of 1868 distinctly states " that they should be entitled to count their years of continuous service with the telegraph companies as years passed in the service of the Crown." In fact, their pay and position under the scheme are regulated by the length of service they have performed at the particular office at which they were located when the scheme was applied. The result is that postal men with eight years are the seniors in pay and position of telegraph clerks with 16 years, and in many cases longer service, who should in all justice be treated with the same consideration. We also find that youths who have failed to pass as telegraph clerks, or who were employed as telegraph messengers and letter carriers, have been appointed as sorters, and are, under the scheme, in a higher position than those telegraph clerks who were previously their superior officers.

Is this, I would ask, a chimerical grievance ? Does it, as you state, affect only the few ? Or could it be remedied by strong local action ? No, emphatically, no ! It is a real, substantial, existing grievance, affecting not the few, but the many. Our twelve years' experience of postal officialism has taught us that, however much we may detest the course, because in our hearts we do detest it, nothing but combination of a united and healthy character can procure our claims the consideration they deserve. While such grievances as these are permitted to remain unredresssed, so long, I am afraid, will the telegraph clerks continue to agitate, and lay their complaints before the public, who are their real employers, even as they are of those permanent officials whose past apathy to our just claims has brought about the present unhappy state of affairs, and driven so many of the best clerks to seek other employment.

I think, sir, I have fully proved my points that the scheme is inadequate, that it has been applied " partially and unjustly," and that our grievances are not mere fancies. Thanking you for supporting our appeal for a Select Committee, trusting soon to see it at work, and agitation in our branch no longer compulsory.—Yours, &c.,

A MEMBER OF THE CONFERENCE.

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).

TO THE EDITOR OF THE ELECTRICIAN.

SIR : The success of an enterprise ordinarily shuts the mouths of objectors against irregularities. But in the case of this corporation its unexampled success aggravates the injustice of which I have to complain. The prospectus issued in December, 1880, states the capital as £800,000 in 80,000 shares of £10 each, of which the first issue was £400,000, and the following is a copy of Section 12 of that prospectus : " Applications for shares should be made in the form accompanying this prospectus, £1 to be paid on application, and £3 on allotment. *It is not at present intended to call up any further capital*, and for any call one month's notice will be given," &c. When in January last I received the report and accounts of the first year's proceedings I discovered that of the 40,000 shares (of which 10,000 went to the vendor company) some favoured shareholders had been permitted to pay up the additional £6, making £10 per share on 3,001 shares, and I thereupon applied for permission (which was refused) to pay up a like amount on the shares allotted to me. A meeting having been convened for the 18th inst. for the purpose of passing the following resolution :—" The directors may from time to time, of their own authority, pay to the members *in proportion to the amounts paid up*, or credited as paid up, on the shares held by them respectively, such bonus and such interim dividends as in the judgment of the directors the position of the corporation justifies," you will, I hope, allow me through your valuable paper to bring under the notice of my fellow-sufferers, the holders of the 26,999 shares on which only £4 has been allowed to be paid, the injustice done to us if these favoured shareholders are to receive in respect of their additional £6 per share the very large profits (capital as well as income) realised by the corporation *in the same proportion* as we do upon the £4 per share, to the payment of which we have been restricted.—

Yours, &c., AN ORIGINAL ALLOTTEE.

July 10, 1882.

DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Not being very conversant with electrical conditions, I shall feel greatly obliged if you will explain the following matter through your columns :—I have two small continuous current dynamos (each working one arc lamp) in use. They are both bolted to the same wrought iron bed plates, but carefully insulated from actual contact by sheet asbestos. These machines run in opposite directions, and one lamp (either one), frequently goes out, or perhaps nearly so, whereupon the other immediately brightens up, as though it received the current which failed to pass through the first. What I wished to know was—if the presence of the wrought iron plate brought this about in any way ? or, was the fact due to the machines being run in opposite disections ? or, would it be possible under the circumstances for one machine to act the part of an exciter to the other ?—Yours, &c.,

WONDERER.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: To this question I have failed to see given any reliable answer, and my suggestion may be equally unsatisfactory. However, when endeavouring to solve a law of Nature, my experience tells me to inquire into and search it out from the simplest form known to us in daily life.

We know electricity is produced to our senses in one of two ways—either mechanical, *i.e.*, by friction, or chemical, *i.e.*, by the conversion of some sorts of matter into other sorts.

I submit that, as electricity is common to all things, its mechanical production has precedence of the chemical, and that the electricity in things partakes of the principle of "storage."

We only know things by what they do. Bearings heat by frictional contact to a very high and even visible temperature.

Two rapidly revolving discs, not in contact, but so close together as to admit only of an air space between them, develop electricity quickly and in a most powerful form from the rubbing together of the molecules of air between the discs.

Let me now observe that the world rolls round itself at the rate of 1,000 miles an hour, and travels round the sun at the rate of 6,500 miles an hour, the atmosphere travelling with it.

Is it not a fact that our planetary system works from east to west by the south, and that our world revolves from west to east? Surely with such motion there must be a "slip" producing friction and electricity.

If there is a "slip," then electricity would be an effect of Nature's laws of friction; but whether that friction produces it *de novo*, or stimulates it into action from a latent state, I am not prepared to say, but prefer the latter theory.

If it is a "primary," there is no use in asking "What is electricity?" but we may ask—Where is its source?—Yours, &c., J. D. SHAKESPEAR.

July 12, 1882.

INDIAN AND ORIENTAL ELECTRICAL STORAGE AND WORKS COMPANY (LIMITED).

A general meeting of the members of this Company was held at the Cannon-street Hotel on the 11th inst., under the presidency of Mr. Ernest Noel, M.P.

The SECRETARY (Mr. H. Cleland Heywood) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen—You are are aware that by the Act of Parliament a company must needs meet within four months of its allotment, and, therefore, this statutory meeting has been called. In an ordinary way I think it is wiser to say next to nothing on such occasions as these, and merely announce that the allotment of the shares was made. On that, in this case, we have the pleasure of telling you that all the shares were allotted, and that the applications considerably exceeded the amount required to be allotted. But what I really wish to say to you to-day is regarding something which has happened since the allotment of shares—something that I believe will be very much to the advantage of this Company. You have probably heard, or may have seen in the newspapers, that an arrangement has been made by the Electrical Power Storage Company with the Faure Company, and it is concerning this that I have to say a few words. In our prospectus we put forward what we considered a very important question in buying patents—that we had a guarantee from the vendors that our patents would stand. The only real fear we had was as regards any possible infringement by our patents of the Faure accumulator, and, therefore, we demanded from the Storage Company, who were the vendors, a guarantee that our patents should stand. We had no doubt as to the superiority of our batteries over those of the Faure accumulator, but we had a fear that those batteries—the Sellon-Volckmar batteries—might possibly be some infringement. The Storage Company were well advised that there was no infringement, but still there might be, and we made it a *sine quâ non* that we should have a guarantee. The scientific opinions we had regarding our own batteries were very satisfactory, especially that of Mr. Cromwell Varley, a name well known in the electrical world, who, to use his own words, said, "It is a wonderful battery;" and I believe that the world will find out that the Sellon-Volckmar is a wonderful battery. There was, however, a rival in the field—the Faure accumulator. We had no guarantee as to that—as to our having no rivals. All that the vendors guaranteed was that the patents were valid. Shortly after the allotment we heard that litigation was threatened between the Faure Company and the Electrical Storage Company. After a time we further heard that these two companies preferred peace to war. I am not going into the question as to the arrangement made between these two companies. That is no affair of ours. Whether it was wise or unwise is no matter to us. What were the details of the arrangement is really immaterial to us. All that we have to know is that an arrangement was made between these two companies that they should work together; but there was a question which was very important to us. Did this arrangement between the two companies have any effect on our Company? Now, it came to pass that the Storage Company which had guaranteed the validity of our patents, had now become the possessors of the Faure patents, of the patent rights of the Faure accumulator as regarded practically the whole world; but, at all events, I only speak of that part which belongs to us, of India and the East. This being the case we felt it incumbent on us to enter into negotiations with what I may call the parent company. Those negotiations were chiefly carried on through Mr. Sellon, the gentleman whose name stands at the head of our patents - the Sellon-Volckmar battery—and I have to assure you that such negotiations were carried on in a manner of great fairness and uprightness. Any one who knows Mr. Sellon knows that in dealing with him you are dealing with a man not only of remarkable cleverness, not only a great inventor, but a gentleman of remarkably upright and straightforward character; and, therefore, in dealing with him I felt that I was secure, in dealing with one who would treat this Company fairly. I may say more—that though these negotiations were carried on chiefly through Mr. Sellon himself, the Electrical Storage Company met our Company in an extremely honourable, and more than conciliatory manner. They met us in a way which I can only characterise as wishing to treat us with the favour with which a father might treat his eldest son. They had taken great interest in the formation of this Company, and they had a full belief in this Company, as I will show you in a few moments, and, therefore, were determined, to a certain extent, whatever might have been their strict rights, to pass over to this Company the whole of the patent rights of the Faure Accumulator as regards India and our other territories. The terms for which this important concession was given—for I will explain how it was an important concession in a moment—were simply these:—As regards the whole amount we were to pay to the Electoral Storage Company, that remained the same. The only difference that they demanded of us was a variation as to the mode in which the payment was to be made. In the first place, you are aware, as you could see in our prospectus, that we were to pay £25,000 by way of royalty. This royalty might have been spread over some time—it might possibly, if we were not very successful, have been spread over some years. We have, however, now made an arrangement with them that that £25,000 for royalty shall be paid within twelve months by instalments. There was another arrangement which you may recollect was in our prospectus—that we were to pay £50,000 in shares, with the option of paying it in cash. Most vendors are anxious that they should be paid in cash. I have very rarely heard of a vendor company that was desirous, specially desirous, of retaining the shares or having the shares of any subsidiary company given to them: but as I said just now, the Storage Company think well of us. I think they have reason to, but at all events they do think well of us, and they were desirous that we should have part of the option, as regards 5,000 of these shares, or £25,000, taken away—that we should hand over to them that £25,000 in shares without our having the option of paying them in cash. We thought that this was a very fair concession to make, and therefore as regards the option of half the shares we were to transfer to them, we have given it over to them, and they will certainly now be given 5,000 shares, and the remaining £25,000 will be given in shares or in cash, as we may elect. Beyond that we have paid nothing for what I shall now, in a very few words, try to point out are the advantages we have gained from the concessions we have obtained. I may say at once that these concessions would not have been granted to a company differently situated from ourselves. It was only in consideration of the special guarantee they had given us, and the consideration that we had so early entered into the field in these negotiations, that the Storage Company felt themselves justified in making such very easy terms with us in this manner. But, perhaps, some one will say, what is the advantage of the Faure patents to us, as you say yours are the better of the two? I do say, and I strongly affirm it, and I believe that the world will know it ere long, that the Sellon-Volckmar as secondary batteries are very much better and far stronger, and therefore are of far more commercial importance than the Faure; but in saying that I do not want to detract for one moment from the value of the Faure accumulator, and the Faure accumulator has some advantages which the Sellon-Volckmar has not, inasmuch as the Faure accumulator is known, I may say, almost throughout the world, whereas, however much it may be known hereafter, the Sellon-Volckmar battery is at the present moment not known, though we hope it very soon will be. Therefore, there is that great advantage—that we are now possessors of a patent so well known and so highly thought of as the Faure accumulator. There is also another great advantage—an advantage that is not to be lightly estimated by us, and that is that we get rid of what at present appears, and I believe I may say appears almost positively—the only litigation we could have entered into as regards any one attacking us. We may eventually have to enter into litigation to prevent our patents from being pirated, but as regards any attack on us, by having become the possessors of the patent rights of the Faure accumulator we have got rid of all litigation. There is something still further than that. We have also got rid in India of what would, at all events for a time, have been a rival. We have now possession of the sole accumulators that are commercially of value. I am not prepared to say, in the present state of electrical science, what advances may be made. I am not prepared to say that there may not be in future some better mode of storing electricity than by our battery. All I can say is this—that at present there is none known, and, as far as we can see, there is not one likely to be discovered for some time to come that will not be an infringement of our patents. For some time, therefore, we certainly have a monopoly of what are, perhaps, the most important rights that there can be in the present condition of electrical knowledge. There is something else. In addition to all this—and I think this alone would show us that we have obtained in these patents something of real value to our Company—it enables us to manufacture our batteries at somewhat less cost. I cannot go into the details of that, and you must merely take it from me - but I have had it on good authority—that the manufacture of our Sellon-Volckmar batteries, which are the ones which we shall continue to hold and use, may be somewhat improved, but will certainly be somewhat cheapened in their production, and that is so much clear profit to us in the future. I cannot say what may be the future of electrical science. I cannot say what may be the future of either the use of electricity, or the means of storing electricity, but I can say this, and I think we may congratulate ourselves on it, that already it has been proved that the storage of electricity is a great advance in the progress of mankind in

Digitized by Google

enabling us to lay hold of some of the powers of Nature which up to this time we had not been able to lay hold of. As just one illustration I may say that we are at this moment engaged in negotiations—I may say negotiations are very nearly completed, and I trust to get a telegram very soon to say that they are completed—by which we shall be the possessors of the natural force of a waterfall in one of our territories, and the horse-power in the waterfall will be at once transmuted into two things. One will be the lighting of a town, which will be done by a company that is ready to give us orders for batteries for that purpose; and the other will be for motor power in carrying out some important Government works in its neighbourhood. This is only just an illustration of what is in store for us. Our field is great. I believe there is no company except the parent one that will rank higher than our own as to the territories we possess. I believe there is an opening in India both for electric lighting and the use of electricity as a motor power that is not surpassed in any other country in the world. Therefore I think we may look forward hopefully, knowing the difficulties we have to encounter—difficulties from the inexperience of our electrical engineers, difficulties of all sorts that must be encountered when a new power, as it were, is brought under the dominion of man, and is being pressed as a commercial undertaking. Taking the most sober views of all those difficulties, which we are quite prepared to encounter, I think I may say with confidence that there is a very bright future for this Company. There was just one point I omitted to allude to in speaking of the terms regarding our becoming the possessors of the patent rights of Mr. Faure, which was this: that, of course, the Electrical Storage Company is no longer required to give us a guarantee. We forego the guarantee they then gave us, as the Board consider that we have secured something far better than a guarantee, by securing those patent rights which alone could or might have endangered our patents. I do not think I have any other question to touch on to-day. I hope that next year, if I have the honour of addressing you again, it will not be to say what we hope to do or may do, but what we have done, and I look forward with very considerable hope to be able to say something that will be very gratifying to all the shareholders of the Company. I will ask Lord Crawford, one of our directors, who is well known in the scientific world and also in connection with electricity, to say a word or two as regards the batteries themselves. It might be interesting to the shareholders if he would do that.

Lord Crawford and Balcarres: Mr. Chairman and Gentlemen—It would be very difficult to say anything on the subject of the batteries without actually going into a long scientific exposition of their method of construction and their uses, because the chairman has already laid before us in detail the uses of these batteries, and the methods how they can be used, without actually going into the practical mechanical differences between the Sellon-Volckmar battery and the Faure accumulator. I think, unless I were to do that, there would be very little for me to say. I am sure the chairman has gone most carefully into the whole matter. There is one thing perfectly self-evident to any one who studies electric lighting, or has anything to do with electricity, and that is that it is an absolute necessity that there should be the means of producing electricity at a certain given time, and of putting that electricity away or storing it till such a moment as you may desire to utilise it. Without some means of doing this, electric lighting is practically commercially impossible. I refer, in saying that, not to the lighting of docks or streets, but to the use of the electric light for domestic purposes, or for any place which could not be characterised as a large place. I do not think the science of electricity is sufficiently advanced yet to work the light in houses, in rooms, to have it under control—I am speaking of incandescent lighting—without having storage cells, by which you may put away your electricity till you require to use it. The question is, how best to put away the electricity, and there is no doubt that storage cells, or the Faure accumulator, is the only practical way of doing it. A few years ago the Faure accumulator made a great sensation throughout the world, but since then busy brains and clever men have been at work, and Mr. Sellon has produced a battery which the Company say is superior to the Faure. I do not wish to go into their merits, as we are perfectly friendly, but if the Sellon battery was an improvement over the Faure accumulator Mr. Faure was the only rival that Mr. Sellon had in the field when the arrangement was made between them. There have been batteries called storage batteries by numbers. You can make one by merely decomposing water and then let it recompose. That is a storage battery, as it is a question of force laid by, but it has no great energy in it, and it is costly to produce. The question of these batteries, or, rather, of the position of the Company, is that we hold now the Sellon battery, which we may call No. 1, and also the Faure accumulator, which we may call No. 1*. They are both in the front rank, and now being amalgamated I think there is no reason to fear any danger of being improved on. The great difficulty of improving on the Sellon battery is that, so far as I remember, it will reproduce about 80 to 90 per cent. of the amount of energy which is placed into it. Therefore, any person who wishes to improve it has only 10 to 20 per cent. to improve on, and that is very small indeed when you come to think of the difficulty that has been met with in producing a battery that actually does reproduce such a percentage. I have also been informed that the Sellon battery has not been asked to perform all it can do. I do not think I need detain the meeting further.

The Chairman: If any shareholder would like to ask any question I should be most happy to answer it. It is not, however, like the next time, when there may be many questions to be asked as to our working; for at present there is no working, though I hope that the first batteries will be delivered this week, and that they will be tested this week or at the beginning of next week. We have purchasers for those batteries, and for as many as we are likely to obtain for the next few months, and before those few months are over I have no doubt that we shall have many more purchasers. I am very glad at the point having being brought out by Lord Crawford, that incandescent lighting for domestic purposes is simply an impossibility without storage. I am connected with a company that is anxious to produce incandescent lighting, and that company has stopped its incandescent lighting till it could obtain these storage batteries, because it felt that it was so unsatisfactory to have any lighting that you could not use just as you use gas—to use as little or as much as you like—that you might feel that you had your supply at hand, and that you had no fear of a sudden extinction of the light, and of the house being left in the dark by the failure of your engine or anything else. It must, in fact, be self-evident, I think, to any one who thinks about it, that storage is absolutely essential for the lighting of houses.

Mr. Boyd observed that Lord Crawford had stated what was the loss of power in the Sellon-Volckmar battery, and he would, perhaps, say the loss in the Faure accumulator.

The Chairman: I should not like to give an opinion on that subject—as to the Faure accumulator. Our own opinion is that the Sellon battery is better, and, great as was the advance made by the Faure battery, we believe that the Sellon is an advance on that. As we have not yet had the Faure batteries to work with, I should not like to give any opinion on that subject at all. I have often conversed with scientific men on that subject, I have seen the Faure battery at work at Paris, but I should feel that it would not be just to those who think highly of the Faure accumulator to give an opinion on that subject. We can only speak of what we are possessed of, because our scientific experts have already tested them. I dare say we shall be able next year to give you that information more completely. I think I may now declare the meeting at an end. I hope to have the pleasure of meeting you next year, when we trust to have some very good results from our working in our Indian Empire.

A vote of thanks to the chairman was then proposed, seconded, and carried unanimously, and in reply

The Chairman said: I beg to thank you, gentlemen. It has been a very pleasant meeting, and I hope it always will be with the Indian and Oriental Storage Company.

The meeting then separated.

THE EASTERN TELEGRAPH COMPANY (LIMITED).

The twentieth half-yearly ordinary general meeting of this Company was held on Thursday, the 13th inst., at the Terminus Hotel, Cannon-street, under the presidency of John Pender, Esq., M.P.

The Chairman opened the proceedings by formally requesting the secretary to read the notice convening the meeting.

The Secretary (Mr. George Draper) accordingly read the notice, and subsequently the minutes of the 19th half-yearly meeting held on the 2nd February last.

The Chairman: Gentlemen—Is it your pleasure that these minutes be signed?

The meeting having signified their assent, the chairman signed the minutes.

The Chairman: Gentlemen—I presume you will take the report as read. You have had it in your hands for some days. As usual, I shall refer to some items in the report so that you may have a more accurate idea of the working of our system during the last six months. The revenue for the six months ending the 31st March, 1882, amounted to £321,811, against £302,159 in the corresponding period of last year, being an increase of £19,652. The increase of traffic is attributable to the increased receipts generally, and I may also say to the traffic which is now being carried on from the South African cables. The Indo-European line was interrupted during November and December, and again for a fortnight in the middle of January. The Great Northern Company's route to China was simultaneously interrupted in November and January, so that during a month and a half the state of the traffic between India, China, Australia, the far East, and Europe, and America was carried by the cables of the Eastern Company. The ordinary expenses of the Company were £75,141, against £67,754 in the corresponding period of last year, or an increase of £7,387. This increase is accounted for as follows:—The sum of £1,000 has been written off the cost of the Lipari and Messina cables. This is capital expenditure, but in accordance with the report of July, 1881, the directors will write off gradually the whole cost to revenue, the total amount being about £5,000. In other words, we are taking out of revenue an amount of money to pay for this Lipari cable, from which we receive an annual subsidy, so that in a very short period of time we shall have wiped out that amount instead of adding it to capital. In the corresponding period last year was a charge for the staff endowment assurance for four months only, though this half year we have a six months' charge, consequently the increase is in proportion. There is also £216 for expenses in connection with patents, and £421 for expenses of the Paris and Crystal Palace Electrical Exhibitions, at which it was considered that our system should be fairly represented, and any one who visited those exhibitions would see that the displays were not done in a very expensive way, and that after all our Submarine Electrical Exhibition was, perhaps, the most important of all. As to the salaries and wages, travelling expenses, land lines, stationery, and printing, full details can be given. We carry to reserve (and I am very much pleased to say it) £75,000 against £70,000 last year, and we pay a dividend of 5¼ per cent. Had it not been for the large expenditure in repairs to cables the amount we could have put to reserve would have been considerably increased. The reserve fund now amounts to £490,817. Repairs to cables, I am sorry to say, come to a large amount—£40,269 against £29,942, or an increase of £10,327. Well, this is a very large sum, and I only hope it will not continue as large. In all these repairs which we are making to our cables we are putting in new portions, that being all done at the cost of revenue. We are, therefore, maintaining our system in a thoroughly efficient state. The particulars of the ships' movements will be seen in Abstract C of the accounts. The expenses at the stations show an increase of £5,382. One item of increase is salaries and wages, which are £1,617 more than last year. This is owing to increases granted to the principal officers and clerks of the Company in accordance with a resolution of the board that, directly the yearly traffic reached half a million, an increase should be granted to several of the staff who had been in the service of the Company since its incorporation. The travelling expenses were heavy, in consequence of a large number of the staff being entitled to leave of absence after a period of five or seven years of foreign service. I am quite sure the gentlemen I am addressing will agree that the principle we have laid down of allowing our young men after five or seven years' service in India leave of absence to return home is a very good course. They go back to

Digitized by Google

India and other parts with renewed health and renewed vigour. It is a peculiarly monotonous life that they lead, and it is very desirable that they should get out of the groove they are apt to get into in a period extending over five or seven years' foreign service, and we consider that in the interest of the young men themselves, and more immediately in the interests of the Company, that these changes should take place. The next important increase is the expenses of stationery and printing, which is caused through a larger supply being required for our more important stations, owing to the very considerable increase of traffic. As to the working expenses at stations, the salaries and wages in 1882 were £31,982, against £30,365 in 1881. The travelling expenses were £1,955, against £1,105. There are a number of other details that I have here, but these sum up the whole thing. Our expenses at stations were £53,474 in 1882 against £48,092 in 1881, and there was a net increase of £5,382. I have now given you a pretty fair idea of the expenditure, and I have some more figures before me. I am quite ready to answer any questions as to details, but the result of the general expenses in London is an increase of something like £477 in certain items, and with a decrease in other items of £816, so that the net increase is £166, which is not very much, looking to the very considerable increase of labour that has been necessary, owing to the additional operators required in consequence of the increased traffic. Having given you these details I think I may now make some general remarks which will interest the shareholders. The first is as to the state of our cables. Well, during last year we have had more than the ordinary amount of repairs, as I have just indicated, more particularly in the Bay of Biscay. We have had two steamers at work there, and it has been, perhaps, the most prolonged repair we have yet entered upon; but reading, as I have done, morning after morning that the ships were obliged to run into harbour on account of the weather, I infer that the continuous rough weather is the great cause of the delay in carrying out those repairs. We received a communication only this morning from the captain of the "John Pender," which is very satisfactory so far as it goes, but it would have been much more satisfactory had he announced that the cable was repaired. However, he states that they are in harbour from stress of weather. He goes on to say that he hopes to grapple the cable in 2,500 fathoms of water over a splendid bottom, and that "weather and sea permitting, I have every hope of being able to complete it, as the cable is apparently in excellent condition." I may tell you that last week, as Sir James Anderson reminds me, they had the cable up on board the vessel from 2,150 fathoms deep. They had it on board, but the ship lurched, and the cable went over. That is an accident that will occur, but this shows you that we can certainly grapple the cable, and, therefore, a thing is not lost if you know how to find it [laughter]. I hope any morning now, as we are looking for finer weather (and we have had very little fine weather yet in these latitudes), to have the cable repaired. The next remark I have to make is as to the state of the cables in the Red Sea. We had two faults in the Bombay cable. We have repaired one of these faults, but the other we have been obliged to delay owing to the monsoon coming on. It so happened, however, that at that moment the state of affairs in Egypt necessitated our bringing our steamer, the "Chiltern," which we generally keep in the Red Sea, to Alexandria, and I think that those who are watching the state of affairs in Egypt will observe that the "Chiltern" has done a very great deal of good work [hear, hear]. I think we may congratulate ourselves on the fact that without the "Chiltern" you would not have had the same amount of news, and that the Government would not have been able to guide and direct affairs as they have done, had it not been for the Eastern Telegraph Company's system. I may say that we have placed the "Chiltern" under the orders of Sir Michael Seymour, the British Admiral.

Sir James Anderson: Sir Beauchamp Seymour.

The Chairman: Sir Beauchamp. Sir Michael Seymour is a very old admiral, and Sir Beauchamp is likely to prove that he carries on the good old name with honour and credit [applause]. The "Chiltern," I may mention, is now at Alexandria, and is doing good work, but I am sorry to say that the state of things at Alexandria has interrupted our system across the isthmus. Two days ago our system was interrupted, but you need not be alarmed so much about that, because, through the foresight of your directors, we entered into arrangements some few years ago with the Indo-European Company for a joint-purse arrangement, and that some more arrangements will carry us with our present returns, I hope, far beyond the time that will be necessary for us to re-establish our connection with the East. I hope, also, that there is no crisis of this kind that does not make men think, and I believe that the result of this crisis will be in all probability to give us increased communication with our connections in the East. I have referred to the Lipari cable. It is working most satisfactorily. It is a small thing, but it is satisfactory so far, that the Government of Italy are satisfied, and we are satisfied with the results we receive from it, and I will just remind you that we are not going to burden capital with it, but that we shall pay it from revenue. There is another important point to which I desire to draw your attention, and that is the Trieste-Corfu cable. At the last meeting, when I had the honour of addressing you, I told you that there had been many attempts by those whose business it is to obtain concessions, and get something out of these telegraph concessions, to get a concession from Austria to connect Egypt with her territory. They again invited tenders, and some of our friends with whom we are on good relations obtained that concession, and we have made arrangements, which will be brought before you by resolution, to secure that and incorporate it in our system. I may say to you that it is very important to us, looking at the great network of telegraphy we have got in the Mediterranean and the Levant, that we should hold any new work of this kind in our own hands. I think I referred to this on a previous occasion. The word "monopoly" is not a pleasant word, but I always meet such a remark by this statement—that it would be most difficult in these waters, frequently in confined parts, if competitors were to come there. It would be most difficult to maintain our cables in that case. If one of them broke we might, in seeking to repair it, pick up the cable of our neighbour, and there might be great difficulties through that. I think you will all agree that the dividend we pay now is not large enough for people to say that we are a monopoly. I say the dividends that we are paying, though they are paid steadily, are not such as any man can complain of or insist on competition being invoked to reduce them. At the extraordinary meeting which has been called to take place after this meeting, a resolution will be put to you which I hope you will approve of, enabling us to secure for the Company the Trieste-Corfu Egyptian cable. There is another concession to which I would wish to draw your attention, which has sprung up since I last addressed you—that is, the Tripoli concession. One of the first cables laid was that from Malta to Tripoli. That was a great many years ago. It was laid very much on its own merits—in other words, that a certain traffic was likely to be obtained so as to secure a fair return on the outlay. That cable broke and was abandoned, and in those days the Company was not rich enough to restore it. Time has past on, and I think when I give you one or two figures they will show you that we are justified in looking after this Malta-Tripoli concession. The exports in 1868 from Tripoli were £105,080, while in 1878 they were £477,034. The imports in 1868 were £83,325, and in 1878 they were £358,220. Now let us take the shipping. The arrivals in 1868 were 262, and in 1878 they were 858, the tonnage being in 1868 21,805 tons, and in 1878 105,272 tons; while the departures in 1868 were 260, and in 1878 824, the tonnage in 1868 being 21,919 tons, and in 1878 149,331 tons. Now, gentlemen, there is no greater index of the prosperity of the place, which I think is most remarkable, and one which certainly satisfied us, that, looking at the trade, which is young, we are likely to receive a very good return on the outlay. Our intention was to recover the cable—part of the shore end—but we have been very fortunate in securing from the Porte a renewed concession, giving the Malta and Tripoli line entirely into our own hands. It is a very important concession, and one, I think, that will give us very good results. A resolution will be put at the special meeting on the subject, and I hope that you will approve of it. As I foreshadowed last year, there is a most important question concerning us which I am now going to bring before you. It relates to the finances of the Company. Our debentures now amount to £882,000, partly bearing 6 per cent. and partly 5 per cent. interest. We think that our property has now taken such a position in the market that it has now become a security such as no one believed in ten years ago. We are, therefore, vain enough to suppose that we shall be able to float debenture stock at 4 per cent., so as to enable us to pay off the whole of our present debentures as they fall due. A special resolution will also be brought before you to confirm that. If we can effect the exchange, and can, on a 4 per cent. outlay, pay for these works which we are going to ask you to sanction to-day, we believe we shall have done a very good business, which I believe will be thoroughly satisfactory to the whole body of the shareholders. When we talk of these debentures you must not suppose that this is altogether additional. It is with a view to take, I hope, a higher financial position in the security market—a position, I think, we are fairly entitled to. I may say now, also, because I think it is right to foreshadow a little of what the policy and plans of your board are—if you read the speech I made to you six months ago—which I myself read this morning—you will find that I foreshadowed something of what I was going to bring before you as to these debentures, but we have other schemes to consider, which we may bring before you later. This, however, I wish you well to understand—that in these days of progress, telegraphy must be more or less prepared. Telegraphy used to follow, I believe; it must now lead; and, as I have said just now, our Indian and Colonial Empires are largely increasing, and demand that telegraphy should increase proportionately. I only wish you to understand that we are not going to let them wait for telegraphy, but that we shall anticipate their wants, and probably I shall shortly bring this matter before you, which I hope you will approve of. With these remarks I beg to move the following resolution:—"That the printed report and accounts of the directors to 31st March, 1882, submitted to this meeting, be and they are hereby received and adopted. That a dividend on the preference shares of the Company to the 30th June, 1882, at the rate of 6 per cent. per annum be paid, less income-tax, and that, in accordance with the directors' recommendation a dividend be and is now declared of 2s. 6d. per share, with a bonus of 1s. per share, both free of income-tax, on the ordinary shares of the Company, making, with previous payments by way of dividend on account, a total payment of 5½ per cent. on those shares for the year ending 31st March, 1882."

The Marquis of Tweeddale: I beg to second that resolution.

The Chairman: Gentlemen—I, of course, desire to hear any observations that you may wish to make on the general remarks I have made; but, as regards the resolutions which are to be proposed at the special meeting, we desire that they should be treated separately. The same remark will also apply to the financial question which I have brought to your notice; probably, therefore, you will defer any remarks you have to make on the Trieste and Tripoli cables till we pass the general report. Has any gentleman any remark to make on the report? Now, if so, I shall be very glad to hear him.

Mr. Stokes: Mr. Chairman and Gentlemen—We have had a very favourable report, and I think that our affairs are going on most satisfactorily. My object in rising to-day, however, is to inquire what the ultimate amount of the reserve fund is to be. When it amounts to a certain sum I suppose we shall get a certain increased dividend, and I should be glad if you would say what you consider is a reasonable sum. It now approaches half a million, and I suppose if you got it up to a million you would consider that sufficient.

Mr. Brixon: I may inform the meeting that I have just returned from the East. I have visited many of the Company's stations, and for good order, management, and respectability I never saw anything better. They were not prepared for my visit, but nothing could be better than the regularity with which our affairs are conducted. Many of the stations you have are by no means paradises, and anything that could make the position of the staff more pleasant will be acknowledged by them with gratitude. I may add, as regards the general management of the concern, that for such an undertaking it surprises me. Perhaps in my position it is hardly for me to say what I think, but I must say this, that the management of the board throughout is highly thought of by most commercial men, and is greatly esteemed by the general public wherever I have been.

Mr. Nicholson: I think I may make one remark, and that is that what is really in all our minds at the present moment is the state of Egypt. I think, if it will not be asking you too much, I shall carry the meeting with me if I ask you to be good enough to give us such information as you can as to events there. It is well known in the City of London that the Eastern Telegraph Company have done everything to give all news as fast

Digitized by Google

as they have received it. I think the position the Eastern Telegraph Company will take up after this crisis will show that our board, our managing director, and the whole of the staff have had but one idea in view, the interests of Englishmen and the country at large. I don't like quoting from newspapers as a rule, but these few lines in a paper of this morning I would ask permission to read:—"It is to the Eastern Telegraph Company, as the proprietors of the sole lines of cable communication with Egypt, that the British Government and public are indebted for the almost unrivalled facilities enjoyed for practically instantaneous transmission of news from Alexandria. Tested by this standard, Mr. John Pender, M.P., the chairman, Sir James Anderson, the managing director, and Mr. Ansell, the traffic superintendent, are entitled to rank among the benefactors of the community. Even before the existing crisis the Eastern Company had earned a substantial claim to the confidence of the mercantile community by the excellence of its general arrangements, the regular and efficient working of its network of lines, and the punctuality and accuracy of its despatch of messages." It then goes on to say: "Of the unvarying attention and courtesy shown by the officials of the line amid these trying circumstances it is impossible to speak too strongly, and ere things return to their normal state it is only fair that such claims to public gratitude should be emphatically acknowledged." I feel confident that this meeting conveys its sincere thanks to our directors and to the managing director for all they have done for us on this occasion.

Mr. HIRST: One gentleman who spoke alluded to the reserve fund. I may congratulate the Company upon the fact that we have at this time nearly half-a-million at the credit of the reserve fund, but at the same time I do not pretend that that is so large a reserve as we should aim at obtaining. To give security to such an institution as this, it is necessary that we should have something considerable to fall back upon. Our capital is £4,500,000, that being the amount of our capital, half-a-million can scarcely be considered a very heavy amount for the reserve fund. At all events, I should like to see a greater accumulation till we should be in such a safe position that nothing would interfere with our moderate dividend in time to come. In a Company of this kind if you have not something to fall back upon an accident may occur that may be very prejudicial, but at present, while we can keep up our reserve fund, and have the good management which has been spoken of, we may feel that our property is safe and secure, and we may look on it as almost as safe as the public funds. We are getting this half year a dividend at the rate of 5½ per cent. I hope that that dividend will continue, and if in the course of a year or so the prosperity of the Company increases—and it seems to be going on very prosperously—it may advance by a half per cent. That, I think, would be very satisfactory indeed, and it is one of those circumstances that we may, I think, look forward to.

Mr. MONRO: One gentleman has spoken about the staff, and it is perhaps invidious where the staff are all good to make any special allusion. I think, however, that an expression from us conveying our sense of what the staff at Alexandria have lately done would meet with the approval of the shareholders generally, and with their leave I should like to move a resolution to that effect. Shortly after the outbreak at Alexandria I received a letter from one of the staff, and I should like to read you this extract:—"Six of us left the quarters about three in the afternoon, and went for a row round the men-of-war, and returned about six, and were going to land, when we accidently met some officers of the ships, who warned us not to go on shore, so we were miraculously saved from being probably all killed. We went and stopped on board Her Majesty's ship 'Invincible,' where we were all well treated by the officers. We came ashore on Monday afternoon, and were escorted to the office by an escort of soldiers and two officers with fixed bayonets. The amount of work we are doing is something fearful. We all have to do double duties, besides taking our turns at sentry duty (two hours). We have blockaded the quarters, and intend to defend it as long as we can." The letter then goes on:—"One of our clerks (Rainier), with three outsiders, started to come down to advise us not to come ashore. The three outsiders were all killed on the way, and Rainier, by a wonderful miracle, escaped with severe scalp wounds on the head and a damaged nose. Our washerwoman, who had a fortnight's washing of ours, had her house broken into, and nearly everything stolen, so we are in the lurch." I cannot help thinking that some little expression on our part would encourage them, as they are in great danger. We ought to remember that in the army and navy men feel that they are acting a patriotic part and watched. [A voice: "They do their duty."] Yes, but they are observed; telegraph clerks are not observed in the same way, and they also do their duty with scarcely any notice at all. I hope the meeting will, therefore, give some expression of the satisfaction with which they have learnt the way in which the staff at Alexandria has done its duty during the late crisis. I would move a special resolution to the proprietors presently to that effect.

Mr. NEWTON: May I ask if the report is true that one of our principal officers at Alexandria was slaughtered in the atrocities of yesterday?

The CHAIRMAN: The first question I have to reply to is that of Mr. Stokes, who asked us what is to be the maximum of the reserve fund. Well, I think it is very difficult for me to give a direct answer, but if you will allow me I will answer it in my own particular way. I think it is most desirable, looking at our capital (with our ordinary share capital and our debentures together we have five millions and a half), that we should have a very considerably larger reserve fund than we have now. We have got a very handsome sum, it is true—nearly half a million, but then, when you name half a million, you must also name five and a half millions, and we have 16,000 miles of cables. Consequently, I think we ought to be satisfied with the comparatively moderate dividend we are now paying until we increase our reserve. It is a very handsome addition that we are making now—£75,000—but if you remember I stated a year ago that I hoped we should be able to put £100,000 a year to our reserve fund, because our system is now considerably increased, and I said that when we were able to add £100,000 a year to the reserve fund it would be a good thing for the shareholders afterwards to get some consideration. Let me, however, say one more word as to the increasing of the reserve fund. If you do not get the benefit in one way you get it in another, and all prudent men like to put by a little out of their earnings if the shares, generally, go up in the markets and you find you have added to the value of your property, though you have not got it strictly in dividends. You must remember that you cannot get it in both ways. If you had not a good reserve fund your property would not stand in the market at the price it stands at to-day, and that it is likely to stand at as our reserve fund increases. I hope that that explanation will be satisfactory to the general body of the shareholders, and you may rest assured that when we get to putting by £100,000 a year to our reserve fund, if any one rises and proposes that something additional should be given to the shareholders I shall be ready to join in the proposal. As regards Mr. Brixon's remarks on the staff I have occasionally in the autumn made a point of going and visiting our different stations as far as time would allow. As you are aware, we have two or three steamers, and it is well for our directors to see what is going on at the stations. It is not a very expensive affair, but it is extremely beneficial. The young men like to see it immensely. They like to see the chairman, the managing director, or any of the directors. Sir James Anderson has visited them occasionally, Lord Alfred Paget has gone there lately; and altogether such visits keep up an *esprit de corps* among our young men which we consider very beneficial. I was never more pleased than at what I was told by the late First Lord of the Admiralty. Mr. Smith went out for a cruise both as First Lord and also in his own yacht afterwards. He said to me, "Mr. Pender, I never was more proud of my country, or an institution connected with it, than on my visit to your offices in the East, and in the Levant." He added, "The young men are gentlemen. I saw the place as compared with other offices there, and it was clean—so tidy and so business-like. All the young fellows were at their work, and everything was going on like clockwork. I tell you that I then felt quite proud of being an Englishman when I saw the institution so well managed." I may now say something further. I was very pleased two days ago at what the First Lord of the Admiralty, Lord Northbrook, told me. Lord Northbrook is, perhaps, one of the first men of business—I will not say in the Cabinet—but in the country. He has the old blood of the Barings in him, and that is shown very prominently in the department. He said:—"I was uncommonly pleased at the cable having been picked up in two hours, re-establishing communication in the morning." We felt extremely proud at this being recognised by a man like Lord Northbrook. The remarks which Mr. Monro made I think I have pretty well answered. I am sorry to say that this morning we have a telegram that a young fellow—a Frenchman, all honour to him—stuck to the office to the very last moment. Our office at Alexandria was burnt down yesterday, and this poor fellow was murdered. It is very sad. While I pay a tribute to his memory for his great courage and devotion to his work, I think it reflects very much on the people who were guilty of such a barbarous deed. As to the other young man, I received a letter this morning. On the day of the massacre Mr. Rainier left the office and went down to warn some of his companions who were going out in a boat to see the Fleet. His object was to save them, if possible. He was almost murdered, and was treated in such a way that, to use his own words, through Providence he was saved; but the two or three who went with him were murdered. These are painful stories to tell, but it is one of those incidents of war that make war so terrible that none of us can even desire it in any way.

A SHAREHOLDER. May I ask the name of the young French gentleman who was murdered?

The CHAIRMAN: Ternant. He was a nephew of the manager of our department at Marseilles. I can only say to Mr. Munro that when our board meets we shall recognise in the way we ought to do the extraordinary devotion to their duties which our staff has shown in the present crisis. I may mention that one of our doctors from the "Chiltern" went on shore to the assistance of an Arab who was severally injured—his leg being broken. This gentleman, without thinking of himself, went and reset the Arab's leg amid cheers from all who saw the act. I mention this to show that we have a good class of men in our service in the East. Mr. Nicholson asks me to give an opinion about Egypt. I wish I could see the end of the present state of things. My own impression is (I give it simply as my own impression) that as out of evil good sometimes comes, I hope (and I trust it may not be a false hope) that the result of all this will be to secure a permanent highway to our Indian and Colonial Empires. To secure that remains with the Government—I only express my own opinion; but, under any circumstances, it will be our duty to see that we secure for India a permanent system of telegraphic communication. I cannot enter into politics here; I think it wise to act on the advice I give to all our young men in the East, and as far as the Company is concerned I know no politics.

Mr. NEWTON: Is the Canal open?

The CHAIRMAN: I have only this morning been at the Admiralty, and I hope that before a long period passes over our heads Port Said will be connected with our system. If our advice had been taken three weeks ago it would have been done now. However, our Government do not, through the routine of departmental system, act as decisively as I should like to act.

Mr. NEWTON: If you get connected with Port Said, what means have you to communicate with Suez?

The CHAIRMAN: That is also under consideration. Thank you for making the suggestion. I think I foreshadowed a little information on that subject, but we have other people to deal with in connection with that work. There is one thing I might say, as it applies to our business. Twelve months ago I suppose that Egypt was perhaps the most prosperous country in the world. The Controllers were receiving the money regularly, the Egyptian Fellaheen were enabled to labour without molestation, and to keep the result of their labours; in other words, they were altogether prosperous. We in this country were receiving our dividends, and every man—bankers, merchants, and all classes of people—believed that Egyptian Stock was about the best investment that could be made, and of course the rate of interest was a considerable temptation. We had, therefore, a large amount of our reserve fund in that stock. I believe myself to-day that if I held Egyptian stock I should not trouble my head about it. I belive long before six months are over, whatever happens, that the chances are that Egypt will pay her dividends. You cannot burn the land, or destroy the people. You may destroy a town, but you cannot wipe out the Nile, and Egypt is a country which will very shortly resume the position she held a year ago. I may be sanguine in that, and war will always cause uncertainty. Looking forward to possibilities, which have really become facts, we sold half of our holding in Egyptian Stock at 91⅜. To-day we could replace that amount at something like 10

Digitized by Google

per cent. less, and before long we may replace it, but we shall fully consider that course first.

Lord ALFRED PAGET: One word in corroboration of what has been said about our staff and their efficiency. I have been out there in my own yacht, and at my own expense, and have visited every station in the East, except Salonica, and what I saw was extraordinary, more particularly the pluck shown. I went to a certain island, Chios, which you all heard of in connection with the earthquakes there. The whole place was in ruins, everyone had left the place. Our station was in ruins, but they had erected a kind of wooden hut, and I saw men working there. I asked them whether they were not afraid? They said "No, my lord, we are not now; we are used to it, and we will remain and do our duty."

The CHAIRMAN: I see that the feeling of the meeting is very properly in favour of this public meeting expressing its full sense of the conduct of our staff, and I will, if you will allow me, read a resolution which has just been drafted, and I will ask Mr. Monro to second it, if the meeting approve of that. The solicitor corrects me and reminds me that we had better first pass the resolution that has already been moved by myself and seconded by the Marquis of Tweeddale. Having put the resolution in the usual way he announced that it was carried unanimously. Continuing he said: The next resolution is this:—"That this meeting desires to record its thanks to the staff of the Company for their services during the past year, and to declare its high appreciation of the great labour and anxiety which the Company's officers in Egypt have recently undergone, and of the zealous and efficient manner in which they have performed their duties under most trying and difficult circumstances."

Mr. MONRO: I have great pleasure in seconding that.

The Chairman put the motion, which was carried unanimously.

The CHAIRMAN: That is the end of the business of the ordinary meeting, and now we will go to the special meeting. The first resolution I have to propose is as follows:—"That the board be and are hereby authorised to purchase and take over the concession from the Imperial and Royal Austrian Government, dated 19th August, 1881 (referred to in the directors' report, dated 3rd July, 1882), for the establishment of a submarine telegraph cable connecting Trieste and Corfu, and the cable recently laid in pursuance thereof, at a total cost not exceeding £67,000.

Sir JAMES ANDERSON: I beg to second that.

The CHAIRMAN: Has any gentleman any question to ask me on that? There being no reply, he put the motion, and declared it carried unanimously. Continuing, he said: The next resolution is as follows:—"That the meeting approves of the board's proposal to lay a new cable between Malta and Tripoli as mentioned in the directors' report, dated 3rd July, 1882." I would just say in regard to that that we have a certain amount of spare cable which we generally keep in reserve, and we shall utilise that cable in laying the Tripoli cable, so that the amount will be comparatively small, and at the same time, as I have shown you by figures, I expect the result will be very considerable from it.

Sir JAMES ANDERSON seconded the motion.

The CHAIRMAN put it, and it was carried unanimously. He then said: —I think it would be well that you should be perfectly informed of the next matter to come before you, and the solicitor will read the resolution.

The SOLICITOR (Mr. Birt): This, gentlemen, is the resolution as to the creation of debenture stock:—

(A) That the board of directors be, and are hereby authorised from time to time to create and issue mortgage debenture stock of the Company to an amount not exceeding one-third of the share capital of the Company for the time being issued and paid up, upon the terms that the aggregate amount of the said stock for the time being in issue, and the interest thereon, shall rank *pari passu* as a first charge on the undertaking and revenue of the Company, the stock to be issued at such times, in such amounts, and on such terms and conditions as the board shall from time to time determine, for the purpose of redeeming by exchange or otherwise the outstanding debentures of the Company, and any other purpose to which capital of the Company may be lawfully applicable.

(B) That the board be, and are hereby authorised to make such provision as they think fit for the registration and transfer of mortgage debenture stock, and for the delivery of certificates thereof, and for the issue of stock warrants to bearer transferable by delivery, and of interest coupons attached to such certificates and warrants or otherwise, and for the conversion of warrants to bearer into registered stock, and of registered stock into warrants to bearer, and generally as to the form and incidents of all documents relating to the said stock, but so that no such provision be inconsistent with paragraph A of this resolution.

(C) That the board be, and are hereby authorised from time to time to purchase in the market and hold and deal with any amounts of such mortgage debenture stock for the purposes of any reserve fund or investment of the Company, and, with the sanction of a general meeting, to apply other moneys of the Company to the purchase in the market of any such stock for cancellation, and, with the like sanction, afterwards to re-issue mortgage debenture stock in lieu of all or any of the said stock so cancelled, provided always that the amount of mortgage debenture stock issued and outstanding shall never exceed the limit prescribed by paragraph A of this resolution.

The CHAIRMAN: That is the first resolution, which I beg to move.

The motion having been seconded, a discussion followed, in which Messrs. Marks, Griffiths, Newton, and Hirst took part.

The CHAIRMAN, in reply, said it was more advisable altogether to issue debenture stock than debentures, as a preference was generally felt by investors to go into a permanent stock rather than terminable bonds. With regard to the debentures outstanding, the holders could retain them until they expired, the directors having no power to deal with them otherwise without the consent of the holders. He then put the resolution, which was carried unanimously.

On the motion of Mr. NEWTON, a vote of thanks was passed to the chairman and directors, which the chairman acknowledged, adding, in reply to a question by Mr. Newton, that he thought it should be understood that British vessels had not been prevented from going through the Suez Canal, they had only been cautioned against passing through, but they could do so at their own risk.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).

Report of the directors for the half year ending June 30, to be presented at the twenty-second ordinary general meeting of shareholders to be held on July 19: The directors beg to submit, duly audited, the balance-sheet and accounts for the half year ended June 30 last, from which it will be seen that the gross receipts, including the balance brought from last account, amount to £21,279 7s. 11d., and the gross expenditure to £5,782 9s. 11d., leaving a sum of £15,496 18s. to the credit of revenue account. Of this, the sum of £3,950 has been placed to the reserve fund, increasing that fund to £47,000. After providing for the preference dividend, a balance of £8,546 18s. remains, out of which the directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax, which will absorb £6,400, and leave £2,146 18s. to be carried forward to the current half year's account. The directors have pleasure in reporting that the cables have continued in good working order.

In the matter of the suit instituted against the Spanish Government at Havana for a return of the tax erroneously levied on the Havana-Santiago business, which was decided by the Court there in favour of the Company, and the decision appealed against to Madrid, appearance has been entered on behalf of the Company, and the case is now on the list of the Section of the Contencioso in the High Council of State waiting to be heard. The date of the trial has not yet, however, been fixed.

At the recent extraordinary meeting to fill up the vacancy in the office of auditor, caused by the death of Mr. Cowan, several shareholders remarked upon the inconvenience of having to call a special meeting in such cases, and suggested the expediency of altering the Articles of Association, so as to provide against similar contingencies. The directors, in order to meet these views, have, with the notice of the ordinary meeting, sent out a further notice of a special resolution, which will enable the shareholders, if they think fit, after the termination of the ordinary business, to effect a slight alteration in the articles to meet the case. The director who retires from the board at this time is Mr. Alexander F. Low, who, being eligible, offers himself for re-election. Mr. Thomas Greenwood, the auditor, who was elected at the extraordinary general meeting in May, in place of the late Mr. Cowan, also retires, and offers himself for re-election.

THE ORIENTAL TELEPHONE COMPANY, LIMITED.

BOARD OF DIRECTORS.

JOHN PENDER, Esq., M.P. (Chairman).
Sir ALEXANDER ARMSTRONG, K.C.B.
Sir JULIUS VOGEL, K.C.M.G.
PATRICK CARNEGY, Esq., C.I.E.
JAMES PENDER, Esq.
THOMAS ALVA EDISON, Esq.
Sir WILLIAM THOMSON, LL.D., F.R.S., M.I.C.E., ex-officio Director and Consulting Electrician.
JOHN P. BIGELOW, Esq.
WILLIAM W. CARGILL, Esq.
Colonel GOURAUD.
The Honourable GARDINER G. HUBBARD.

This Company is formed to provide Telephonic Communication by Exchanges and Private Lines in India, Ceylon, the Straits Settlements, Java, China, Japan, South Africa, Australia and New Zealand, Egypt, Turkey, Greece, and the Hawaian Islands, and elsewhere, wherever the Company may acquire rights.

Exchanges have already been Established in

ALEXANDRIA, CAIRO, CALCUTTA, MADRAS, BOMBAY, RANGOON, HONG KONG, SHANGHAI, AND HONOLULU,

And the Company will shortly open in

COLOMBO, KURRACHEE, CAWNPORE, AND ELSEWHERE.

PRIVATE LINES can be CONSTRUCTED in any of the countries comprised in the Company's field of operations. For further particulars apply to

3, Great Winchester Street, E.C., London, 10th March, 1882. W. G. HALL, *Secretary.*

THE EXCHANGE TELEGRAPH COMPANY, LIMITED.

Head Offices--17 & 18, Cornhill, E.C.; Stock Exchange, E.C.; 27, Regent Street, W.

Incorporated the 28th March, 1872, under the Companies Acts of 1862 and 1867, and by Special License from H.M. Postmaster-General.

This Company will undertake to supply recording instruments, telegraphically connected with the Stock Exchange, by the aid of which Subscribers, at their respective offices, may be kept continuously advised throughout the day of the constantly occurring market fluctuations in stocks and shares.

Instruments are placed in the offices of Subscribers and kept in order by the Company, free of every expense but that of rent, and inspectors visit them daily to supply ink and paper.

Terms: £50 per annum, payable quarterly in advance.

Applications for instruments to be made to the Secretary at the above address.

The instruments supplied by the Company can be had to work either on single or double wires, and to print either on a slip or tape of paper, as has hitherto been the custom, or on a broad band of paper in column form.

The Company will supply householders and others with its

DISTRICT CALL SYSTEM.

By the aid of a small automatic telegraph instrument a Subscriber can at any hour, day or night, call a messenger, cab, or policeman, or give the alarm of fire, and will obtain the required assistance within three minutes of making the signal. Subscribers, when absent from their homes for a season, can leave their houses closed, and have them taken charge of by the Company, and rendered perfectly secure against burglars by a telegraphic communication with the nearest District Call Station of the Company, where a policeman will always be in readiness day and night to respond to calls.

Provincial combinations to work under the Company's Patents will be treated liberally.

The Company is also prepared to supply Municipalities with its system of

STREET FIRE ALARMS

as recommended by H. M. Postal Telegraph Department to the Metropolitan Board of Works for the Metropolitan Fire Brigade, and which has received favourable mention by Captain Shaw in his last annual report.

These Alarms have recently been considerably improved by the Company, and are acknowledged to be the simplest yet constructed.

All communications to be addressed to the Secretary as above.

NORTH-EAST COAST EXHIBITION OF NAVAL ARCHITECTURE, MARINE ENGINEERING, FISHERY, LIFE-SAVING, AND COAST-LIGHTING APPLIANCES.

To be opened at TYNEMOUTH on 6th SEPTEMBER, 1882, for not less than Twenty Days.

PATRONS.

His Grace the Duke of NORTHUMBERLAND, Lord Lieutenant of the County of Northumberland; President of the Royal National Lifeboat Institution.
The Most Hon. the Marquess of LONDONDERRY, Lord Lieutenant of the County of Durham.

PRESIDENT.

The Right Hon. the Earl of RAVENSWORTH, President of the Institution of Naval Architects.

VICE-PRESIDENTS.

The Right Hon. EARL PERCY, M.P.
Sir WM. GEO. ARMSTRONG, C.B., President of the Institute of Civil Engineers.
PERCY G. B. WESTMACOTT, Esq., C.E., President of the Institute of Mechanical Engineers.
With others.

Sections.	Presidents.
Naval Architecture	Charles Mitchell, Esq.
Marine Engineering	F. C. Marshall, Esq.
Fisheries	J. M. Ridley, Esq., Chairman of the Tyne Salmon Conservancy.
Life Saving	Commander C. F. W. Johnson, R.N.
Coast Lighting, &c.	Capt. Watson and Capt. F. Smith, Trinity House, Newcastle.
Civil and Sub-Marine Engineering	P. J. Messent, Esq., Engineer to the River Tyne Commissioners, and H. H. Wake, Esq., Engineer to the River Wear Commissioners.

In connection with the Exhibition there will be a LOAN DEPARTMENT, and the committee will be glad to receive exhibits of all objects of marine interest. WORKMEN'S approved MODELS, EXHIBITS of COAL and COAL SHIPPING APPLIANCES will be received. An Exhibition of ELECTRIC and other PATENT LIGHTS will be included.

Diplomas and Medals will be awarded.

Applications for spaces must be made before 1st August.

GEO. RENWICK, Hon. Sec.
SIDNEY OLD, Acting Secretary.

Offices: 21, Collingwood-street, Newcastle-on-Tyne.

INSULATED ELECTRICAL WIRE, Silk, Cotton, or India-rubber covered. Conductivity guaranteed. German Silver Wires for Resistance. Braided Handle Cord, Silk Cord for Electric Bells, &c.—WILLIAM RICKARD, Derby. London Agent (stock kept), EDWIN HOLLOWAY, 2, Gutter-lane, E.C.

TELEGRAPH CONSTRUCTION and MAINTENANCE COMPANY (Limited).

NOTICE is HEREBY GIVEN that the TRANSFER BOOKS of this Company will be CLOSED from the 10th to the 18th inst., both days inclusive, preparatory to the payment of an ad interim dividend of 12s. per share to all Shareholders on the register on the 10th inst.

By order, E. DICKENS, Secretary.

38, Old Broad-street, London, E.C.,
July 7, 1882.

CITY OF WINCHESTER.—The General Purposes Committee of the Town Council are prepared to receive TENDERS for LIGHTING the PUBLIC LAMPS of the City for one, two, or three years.

Full particulars to be obtained at the Town Clerk's Office. Sealed tenders to be delivered to the undersigned on or before the 19th inst.

The Committee do not bind themselves to recommend the acceptance of the lowest or any tender.

WALTER BAILEY, Town Clerk.

Guildhall, Winchester,
July 6, 1882.

PATENT OFFICE RESEARCHES.—An OXFORD GRADUATE, experienced in ELECTRICAL SUBJECTS and in the Investigation of Scientific Books and Documents, undertakes CONFIDENTIAL RESEARCHES for INVENTORS and others.

Not being a Patent Agent he has no interest, but that of his clients, in determining the exact Scientific and Commercial Position of all matters submitted.

Address "X.B.," Office of Electrician, 396, Strand.

SLIP

Brazilian Telegraph Company.—The traffic receipts of this Company for the week ended July 7 amounted to £2,698.

Telegraphic Extension in Canada.—Telegraphic communication was established on June 23 between Winnipeg and Rapid City.

Society of Arts.—The Council of the Society of Arts have elected Dr. C. W. Siemens, F.R.S., as their chairman for the ensuing year.

British Guiana.—It is stated that the use of the telephone is spreading among the mercantile offices in the capital of British Guiana, West Indies.

Electric Light in Canada.—It is stated that large spars, 70ft. high, have been constructed for use in lighting the Chaudière Canal by electric lights.

Electric Light in Leeds.—It is stated that the Leeds Corporation have decided to light their Free Library, now in course of erection, by incandescent lamps.

Change of Name.—The company until lately known as the Electric Light and Power Generator Company will henceforth be known as the Maxim-Weston Electric Company.

Globe Telegraph Company.—The directors of this company announce a dividend for the quarter just ended of 3s. per share on the preference shares and 2s. 9d. per share on the ordinary shares.

Telegraphic Extension in South Africa.—Amongst other Bills that have been read a third time in the Cape Town Assembly is one providing for a loan of £300,000 for the construction of telegraph lines, &c.

West Coast of America Telegraph Company.—The gross earnings of this company—traffic and steamer—for the month ending June 30th, amounted to £3,425, against £3,405 in the corresponding period of last year.

The Telephone in Canada.—News from the Dominion says that the police telephone system in Toronto is to be greatly increased, and that several of the lumber camps on the Gatineau have been connected by telephone.

Telegraphic Communication with the Suez Canal.—The *Daily News* believes that the means of maintaining direct telegraphic communication with the Suez Canal is now under the consideration of Her Majesty's Government.

Telegraph Extension in Tasmania.—According to recent news from this colony, the new telegraph line from Mount Bischoff to the west coast had been commenced, under the superintendence of Mr. Fahey, inspector of telegraphs.

Western and Brazilian Telegraph Company.—The traffic receipts of this Company for the week ending 7th inst. were £1,719, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

Electric Light at Worcester.—An exhibition of art and industry was opened in this city in the early part of this week under the title of the "Worcestershire Exhibition." It is partially lighted by Brush arc lamps supplied by the Hammond Company.

The Telephone in Ceylon.—A public exhibition has been given by the Oriental Telephone Company of instruments fitted by its agents between two merchants' offices in the Fort at Colombo. The extension of the system is, says the *Colonies and India*, likely to spread quickly.

Electric Light at Windsor Castle.—The preparations for lighting portions of this castle by means of electric lights are progressing rapidly. The work is being done by Messrs. R. E. Crompton and Co., and the Maxim-Weston Electric Light Company.

Electric Light on the Embankment.—Owing to an accident to the steam-engine at the works of the Jablochkoff Company on the Thames Embankment, all the lights stopped burning on Monday night at 11:35, and it was believed that two or three days must elapse before they could be lighted again.

West Indies.—The cable between Trinidad and Grenada is interrupted; and, as the cable between St. Thomas and St. Kitts is not yet repaired, there is at present no telegraphic communication with the islands of St. Kitts, Antigua, Guadaloupe, Dominica, Martinique, St. Lucia, St. Vincent, Barbadoes, and Grenada.

The St. Gothard Tunnel.—After many contradictory reports as to whether locomotives propelled by electric energy where to be used in the St. Gothard Tunnel or not, we hear again that the attempt is to be made, and that experiments, for which the sum of 180,000fr. is set apart, are now being made at Berne with this object.

An Electrical Target.—It is stated that a target has been made use of during the Wimbledon meeting, which closes with the present week, which registered each shot fired, or rather each shot that struck it, on a dummy target placed some distance away, and electrically connected with it. This target is reported to have worked extremely well.

Tenders Wanted for Lighting.—The Gainsborough (Lincoln) Local Board are inviting tenders for lighting their district by electric or other lights for one year from the 8th of February next. For further information application should be made to Mr. Samuel Hayes, clerk to the board, 27, Market-place, Gainsborough. Tenders to be sent in by Sept. 2.

New Atlantic Cable.—A telegram from Philadelphia, dated July 18, states that Congress has finally passed the Bill authorising the Baltimore and Ohio Railroad to lay telegraph cables between the United States and Europe, with an amendment forbidding any conbination with other companies to fix rates. The Bill has been sent to the President for his action to be declared.

The Telephone for Diving Work.—A French naval committee has lately reported on the use of the telephone for diving operations. The transmitter approved as best is a small flat circular telephone, having interiorly two spiral magnets superposed. The Gaiffe telephone as a receiver is said to give good effects. Microphones (both the ordinary microphone and the Ader) are pronounced less advantageous.

Accident from Lightning. — A telegram from New York, dated Thursday week, stated that a large brick building in Texarkana, Arkansas State, had been struck by lightning on the previous night (Wednesday), and subsequently fell on an adjoining wooden building, used as a liquor saloon, completely crushing it. The saloon caught fire, and several people who were in it at the time were killed.

Electric Light in Theatres.—Experiments have been made at the Théatre des Variétés in Paris with Swan lamps fed by Faure accumulators, as a means of lighting up the stage. Eighty three lamps were used, and the same number of accumulators, the latter weighing sixty kilogrammes each. The result is said to have been satisfactory. The lamps and accumulators were supplied by the Société Force et Lumière.

Electric Light on Shipboard.—Last week Messrs.

Digitized by Google

Robert Steele and Co. launched from their shipyard at Greenock a steel paddle steamer, called the "Lonsdale," which they have built to the order of Captain James Deane, of Melbourne. She is 200ft. long, 25ft. beam, and 10ft. hold, and intended to be very fast. She is being fitted throughout with incandescent lamps by the Swan Electric Lighting Company.

Direct United States Cable Company.—The directors of this Company have resolved to recommend a final dividend of 5s. per share (free of income-tax) such dividend to be payable on and after the 16th August next, making, with the interim dividends already paid, five per cent. for the year ending 30th June last, carrying forward £282 16s. 8d., after having carried to the reserve fund £9,531 9s. 1d., making it up to £264,000.

Electric Lighting in Belfast Harbour.—The contract for the electric lighting of the lower portion of Donegall Quay having expired the lights have been discontinued. Two of the four lights had, during the past few months, been exhibited during the entire night, and one of these, it is understood, was of very great assistance to sailors who brought vessels into port at night. The lights were supplied and erected by Messrs. R. E. Crompton and Co.

New Dynamo Machine.—We are informed that M. P. Jablochkoff, well known as the inventor of the Jablochkoff system of electric lighting, has brought out a new electromotor, which will, it is stated, give better effects than the motors at present before the public. The cost of the new dynamo machine is said to be small. We believe that an opportunity of seeing this machine will be afforded at the forthcoming exhibition at the Crystal Palace in the autumn.

New Company.—The formation of the Electrical Insulator Manufacturing Company is announced. The capital is £100,000, in £1 shares. The company have acquired an estate at West Wellow, in Wiltshire, which it is stated yields a clay very free from iron, and suitable for the manufacture of insulators, and it is to work this estate and manufacture all classes of insulators, battery jars, &c., that this company has been formed. Mr. E. H. Wilson is the secretary, and the offices are at 31, Lombard-street, E.C.

Electric Light and Gas.—At a recent meeting of the Standish (Lancs.) Local Board, in the course of a discussion on the Electric Lighting Bill and the cost of gas in the locality, it was remarked by the chairman that it was wrong "that they who rode, drove, and slept on a bed of coal, should pay the price for gas they did." Perhaps this may be explained on the same principle that market garden produce, fish, and other things often cost more in the localities in which they are produced or caught than in London.

The Telegraph at Wimbledon.—In the description of the result of the shooting at Wimbledon Camp in the *Daily News* for July 17, the following paragraph occurs:—"Tribute has been paid to one hardworking department at Wimbledon, let the labours of another equally industrious be now mentioned with honour. The telegraphists of the 24th Middlesex and the Civil Service sent no less than 210,000 words over their wires during the first five days of the meeting, and with so much accuracy that not a single complaint of any sort has been made."

The Telephone in Alexandria.—The Chairman of the Oriental Telephone Company has received a telegram from the company's agent in Alexandria, dated 15th inst., stating that, whilst many instruments and nearly all the lines have been destroyed, the Central Exchange is standing, and the general offices are safe, so far as the exterior shows. The agent has been instructed to restore communications as soon as it is prudent to do so. He is connecting the police stations by telephone. None of the company's *employés*, so far as the Board is aware, have lost their lives.

The Mull (Scotland) Cable.—The cableship "Morna," of Leith, Captain Howling, which has been chartered from the London and Edinburgh Shipping Company by the Post Office, has successfully repaired this cable, and telegraphic communication between the mainland and island has been resumed. It was discovered that the cable had been maliciously cut, probably by the crew of some vessel whose anchor had fouled it. After repairing this cable the "Morna" proceeded to Yell Sound, in Shetland, to repair the cable there. In addition to her ordinary crew this vessel has thirty cable men and a staff of electricians on board.

News from Alexandria.—We take the following items of information from the reports of the special correspondents to the daily press:—On Friday, 14th July, it was reported that the "Chiltern," telegraph ship, after transferring the Malta cable to the gunboat "Cygnet," went out and picked up the Cyprus cable—which had been left buoyed the previous day by order of the admiral—spliced it, and paid out four miles, and returned to her former position, having both the Cyprus and Malta cables on board. She was then (Friday) lying half a mile from the Lighthouse Battery, and in close communication with the admiral.

Severe Thunderstorms.—On Monday week severe thunderstorms took place in Scotland. At Pityot, near Muchalls, in the Stonehaven district, the farm buildings were struck and two cows killed. On the previous Saturday, at Blackhole Farm, near Brise, in the Banchory district, a flash of lightning killed two cows standing in the byre, knocking down a woman who was entering the byre at the moment. On Wednesday week the Braemar district was visited by a very heavy thunderstorm, which is reported to have caused considerable damage to the telegraph poles and trees in the neighbourhood. At the Post Office communication was interrupted owing to the coils of the instruments being fused.

Why the Electric Light Goes Out.—With reference to our Note of last week under this head, it is but fair to Messrs. Siemens Brothers and Co. to give the following extract from Mr. Haywood's report to the Commissioners of Sewers. He says:—"In District No. 3 (Siemens') there were 34 lamps, each assumed to be alight for 4,300 hours during the twelve months' experiment, which is equal to a total of 146,200 hours' lighting of a single lamp. The total number of failures in the lighting from all causes was 320, and their aggregate duration about 832 hours of a single lamp, or about ·57 per cent. of the entire lighting of the district for twelve months." In the district lighted by the Brush lamps the percentage was 2·21.

The Secresy of Telegrams.—In reply to Mr. Puleston, who asked the Postmaster-General whether he had now considered the question of destroying telegrams and the insurance by that means of the same freedom and secresy for telegrams as for communications by letter, Mr. Fawcett stated in the House of Commons last Thursday week that the practice of the Post Office had hitherto been to refuse to produce telegrams in court except upon a request by the sender or receiver, or upon the order of the judge. Some doubt having been expressed as to the legality of the course followed by the Department, he proposed to insert a clause in a Post Office Bill about to be introduced which would bring

Digitized by Google

telegrams under similar provisions as to secresy as were now applicable to letters.

India Rubber, Gutta Percha, and Telegraph Works Company.—The next half-yearly general meeting of this company will be held at the Cannon-street Hotel, on the 25th inst., at 12 noon, for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend. An extraordinary general meeting of the company will be held subsequently at the same place for the election of an auditor of the company in the room of Mr. James Cowan, deceased. The company's share register will be closed from the 18th to the 26th inst., both days included. The directors state that the business for the past half year has been satisfactory, and they recommend an interim dividend of 5 per cent., or 10s. per share, payable on the 26th inst.

The Field Telegraph for Egypt.—A daily contemporary, speaking of the preparations being made for a campaign in Egypt, says:—"C troop of Royal Engineers will take out the most perfect field telegraph that has ever been prepared, and ten thousand poles have been got ready for it in the Royal Carriage Department. The poles, which are rather slender, are painted in conspicuous rings of black and white, and are shod with iron, so as to be easily planted in the ground. For several reasons an overhead telegraph is preferred to any other, and for a temporary use, as in this case, the light poles, which can easily be removed from place to place, are regarded as especially advantageous. The supply of wire being virtually unlimited, the telegraph may extend to about 250 miles."

Electric Light in Salford.—After four years' trial of the electric light, Mr. J. Bury, dyer and finisher, of Salford, near Manchester, has greatly extended its use in his works. The making-up room, formerly lighted by ninety gas burners, is now fitted with sixty British incandescent lamps, the change in the lighting having also brought about a better condition of the atmosphere of the room. By means of a switch, the foreman can light or put out any of these sixty lamps at will. The dye house is also lit by two Brockie arc lamps, thus enabling colours to be matched at night as well as in the daytime. The lights are driven by Gramme dynamo machines. The lights and machinery have been supplied and erected by Messrs. H. Bury and G. Tyndall, of Manchester, who are the local agents of the British Electric Light Company.

Telegraphic Communication with India.—Under this head, Colonel Fred. Burnaby writes to *The Times* of July 18 as follows:—"It may not have occurred to some of your readers that in the event of our relations with the Porte being broken off, England's telegraphic line of communication with her greatest possession—Hindostan—would be liable at any moment to be cut. Passing, as the wires do, one through Constantinople and Bushire, another through Odessa and Teheran, and the remainder *viâ* the Delta and India, we are practically dependent upon our friendly relations with the Mahomedan States for our electric communications with Hindostan. The Cape of Good Hope is united by wire with Aden and Bombay, Lisbon is connected with Cape de Verde; would it not be wise, without delay, to continue that line through St. Helena to the Cape, thus making us independent of any hostile Mahomedan combination?"

Telegraph Clerks' Grievances.—A meeting of the Dublin Telegraph clerks was held on Saturday night in Dublin, to receive the report of their delegate to the late conference held in London. The report stated that the feeling amongst the delegates was one of universal dissatisfaction at the inadequacy of the late scheme of revision, and at the manner in which it had been applied. The following resolution was adopted:—"That inasmuch as the Postmaster-General has declined to re-open the question of the settlement of our grievances, and has refused an independent investigation of the complaints made as to the application of the late revision, we regard his action in suspending Mr. Crichton, of Liverpool, for his condemnation of the manner in which the scheme was applied as being both unjust and arbitrary. That this meeting pledges itself to support the central committee in any steps they may decide upon relating to Mr. Crichton's suspension."

The Electric Light at Reading.—We have previously mentioned that during the late Agricultural Show at Reading Messrs. Heelas, of Minster-street and Broad-street, lighted up their extensive premises by electricity. The experiment was very successful, and we are told that over 33,000 visitors went to see it. The whole arrangements were carried out by the Electric Light and Power Generator Company, under the direction of Mr. Massey, and worked without a single hitch. For several days the engine ran during fourteen consecutive hours, the rooms being darkened so that the light was kept going during the day as well as in the evening. The visitors were particularly interested to see incandescent lights in water, lights overhead, and sewing machines worked by currents along one wire. Although mentioned before, we may again say that the Maxim incandescent and the Weston arc lamps were used during these experiments. The exhibition was continued for two or three days after the close of the show in order that the large numbers desirous of witnessing the effective lighting should be able to do so.

Freedom of Speech Amongst Telegraphists.—In the House of Commons on Monday Mr. S. Macliver asked the Postmaster-General whether it was true that a telegraph clerk had been suspended without pay for a fortnight, on the ground that he had made a speech (which he was not allowed sufficient time to explain or justify) at a meeting of telegraphists; and whether in future Post Office *employés* were to be debarred from meeting and discussing their affairs under similar penalties?—Mr. Fawcett replied that the telegraphist in question, according to the report of a speech of his in the newspapers, had charged his superior officers with official favouritism; and when called upon to correct the report or else to substantiate the charge, he at first declined to do either the one or the other, and afterwards offered to substantiate, if a fortnight were given to him for the purpose. Mr. Fawcett considered that in making a public charge of such grave delinquencies without being in possession of proof of its correctness the clerk had committed a very serious offence, and he had accordingly suspended him for a fortnight without pay.

Electric Light in the City.—At the meeting of the Commissioners of Sewers on Tuesday, the report of the Streets Committee on the recent tenders sent in for lighting the City, which was given in our last issue, was read. Mr. Innes subsequently moved "That the report be referred back, with instructions to forthwith carry out the electric lighting through the tendering companies, with the right of private lighting in the districts for three years added to their contracts, reporting in the first instance on the cost of the street lighting after tenders have been made on the footing of the right of private lighting." There was a good deal of discussion on this motion, but eventually it was lost by 17 votes against 6. A subsequent motion by Mr. Peebles to the effect "That the report of the Streets Committee (of June

Digitized by Google

20th) be referred back to them to consider the advisability of adopting the electric light in the streets of the City, and also to consider the advisability and best means of making arrangements for the supply of electricity to this City for all purposes, with power to consult electricians and engineers thereon, and to report to this Court without delay," had to be withdrawn, as most of the members of the Commission had left by that time.

The FitzGerald and Gumpel Lamps.—An exhibition of these lamps has been given during the week by the Phœnix Electric Light and Power Company, at No. 190, Westminster Bridge-road, S.E. The FitzGerald incandescent lamp is composed of a carbon filament in vacuo, and resembles all other incandescent lamps in that respect, but there are details of construction which are peculiar to this lamp only. The carbon is made from Swedish blotting paper, parchmentised by a new process, and subsequently carbonised. It is then mounted on platinum wires in a glass globe. A third wire of iron is introduced into the globe, and connected with the conductors, and on this wire is wound a strip of magnesium. When as good a vacuum has been obtained as is possible with a Sprengel pump, the glass globe is sealed, and the current turned on for a short time. The iron wire becomes red hot and heats the magnesium, which consumes the last particle of residual oxygen that may be left in the lamp. This the inventor states adds greatly to the durability of the carbon, and the efficiency of the lamp. The Gumpel lamp is on the arc system. As we shall hope to describe this lamp with illustrations before long, we shall not say much about it here. The feed is constant, and it is the positive carbon which is fed forward in this case. The lamp seemed to burn well when we saw it. Both the arc and incandescent lamps were supplied with current from a small Gramme machine driven by one of Marshall and Co.'s portable engines. Mr. Gumpel also showed an invention for steering vessels by means of a dynamo connected by gearing to the rudder, and also with a commutator and other apparatus on the bridge of the vessel. So that by turning a handle to right or left, the helm could be made to follow to starboard or port, as the case might be.

Telephonic Exchanges.—In the House of Commons on Monday last, Mr. Cross asked the Postmaster-General whether he had yet come to any decision as to the application which had been made by various companies for licenses to establish and work telephonic exchanges. In reply, Mr. Fawcett said:—"I have to state that I have received numerous applications to grant telephonic licenses, not only in places where telephone exchanges have been established by private companies, but also where they have been established by the Post Office. Deputations have waited upon me, representing the United Telephone Company and other companies connected with it, strongly urging that in the interest of the public it was desirable that private companies should have an opportunity of competing against the Post Office in those places where telephone exchange business has hitherto been conducted by the Post Office alone. I have had similar applications to allow telephone exchange business to be established in places where the United Telephone Company or one of its branches has an exchange. After giving the matter very careful consideration I have come to the conclusion that it would not be in the interest of the public to create a monopoly in relation to the supply of telephonic communication. I am, therefore, prepared to favourably entertain the proposals that may be made to me by responsible persons to grant new telephone licenses under conditions which may be regarded as giving adequate protection to the public and the Department. In case it may be supposed that inconvenience may arise from the multiplication of wires, I may remark that the license of the Postmaster-General to establish a telephone exchange confers no special power whatever to erect poles and wires on, or to place wires under, any highway or private property. The persons to whom a license may be given will have to make their own arrangements with the local authorities, and with any persons whose property may be affected. It may be well to add that the license of the Postmaster-General confers no authority to carry on telephone business with any instrument the use of which would be an infringement of any patent."

The Origin of Thunderstorms.—On the 7th of July, Mr. B. G. Jenkins, F.R.A.S., read an interesting paper on this subject at a meeting of the Dulwich College Geological Club, held at the Old College. According to the author a thunderstorm is generally regarded as a manifestation of atmospheric electricity. Electricity is without doubt actively present, but its duty is, he maintained, largely to act as a match to produce the chemical unions of which the thunder is the audible effect. If a thunderstorm is the result of an excess of electricity in the atmosphere, it is remarkable that they should be so prevalent in June, when the atmospheric electricity is at a minimum, and not happen in January, when it is at a maximum. That moisture is not the cause of thunderstorms is evident, for moisture in the winter months increases atmospheric electricity, but diminishes it in summer. Besides, thunderstorms are much fewer in number and less violent over the oceans than over the continents. The vast quantities of water in the rapidly-formed thunder clouds are the effect and in no way the cause of the storm. Count Volta showed that gases emit positive electricity when being condensed, and in this and the consequent rapid formation of dense clouds Mr. Jenkins considered the true explanation lay. The condensation was due to a chemical change produced in the union of the oxygen and nitrogen of the atmosphere with hydrogen. The two former are abundant; the difficulty is to account for a large and sudden supply of the latter. There are, however, reasons for believing that the outside layer of our atmosphere is largely composed of hydrogen, and that under certain atmospheric conditions portions of this vast layer are whirled down into the mixture of oxygen and nitrogen around and above us. The mere friction of the particles would be sufficient to produce an electric spark, causing a large portion of the hydrogen to unite with oxygen, forming water; another to unite with nitrogen, forming ammonia; and another to unite with oxygen and nitrogen, to form nitric acid. Each great flash is followed by a sudden downpour of rain, and especially of hail, indicating by the great change of temperature some vast chemical union. This can be no other than the formation of water, which, as is well known, would be accompanied by flame and explosion. The light produced in the sky during a thunderstorm has been divided into three kinds—first, forked lightning; second, sheet lightning; third, ball lightning. The first only of these, he held, was true electricity. The second is the most frequent, and appears to be produced inside the cloud, lighting up the mass, being almost wholly flame, due to the combustion of hydrogen in oxygen, and other chemical changes—the thunder being not so much the noise of the electric discharge as the report of the explosions taking place during the chemical union. Ball lightning is probably not electricity, but a mass of gas in intense ignition. The comparative harmlessness of the last two would seem to indicate their non-electric character.

ELECTRICITY.

ABSTRACT OF TWO LECTURES BY PROF. G. CHRYSTAL.*

LECTURE I.

The subject of this and the following lecture is electricity. This word connotes much that is definitely ascertained, much that is fancied to be known, and much that is confessed by all to be unknown. It is well, then, at the outset, to indicate the route we are to follow through so wide a subject. In the first place, we are to set aside our curiosity as to the real nature of that to which we give the name electricity; we are not to inquire into the nature of the thing itself; we are to turn our backs resolutely on the mystic mazes of molecular physics wherein the dynamical explanation of electricity is doubtless to be found, and to look steadily at the manifestations of electricity in the various phenomena of the laboratory and workshop. Our question is not what electricity is, but what does it do? Nor of its doings are we to be led aside by those phenomena that are little understood, or as yet but feebly manifested. We are to look only at those that are best known, most within our power of calculation, and at the same time, so far as our limited vision goes, most likely to serve our practical purposes. We are to look at electricity as the agent that rings our bells, lights our streets, silvers our spoons—if solid plate happens to be beyond the depth of our purse—and will in the not distant future brush our boots, grind our coffee, and take us quietly to church on a Sunday without disturbing either cabmen or horses. In short, we are to look at electricity as a storer and transmitter of energy.

Energy is another of those potent words wherewith the learned conjure nowadays to the mystification of their lay brethren. It is little understood by the British public, but some glimpse of its meaning is clearly necessary for us to-night, for it is the main thing we are to talk about. The two great difficulties in apprehending it are—1st. That it denotes something which is unseen. 2nd. That the idea which it names is new to this generation. Every one of any education is now familiar with the principle called "Conservation of Matter," but comparatively few have yet grasped the notion of the "Conservation of Energy." We all know that matter is indestructible. To-night must be impressed upon you, along with the idea of energy, the notion that it is also indestructible.

Let us make an indirect approach along an old fashioned road. Let us follow for a moment that metaphysical phantom "Force," on whose real nature and problematical existence my colleague, Professor Tait, has of late thrown so much light. When a body previously at rest to relatively neighbouring bodies begins to move, we explain the fact by saying that force has been exerted upon it. Now, to that I append the statement that in general when force has been exerted and a body has in consequence moved, or been helped in its motion, *work has been done*, and we may say that work has been done by the force or by the exerting agent. You are, of course, all familiar with the fact that two very different results may follow from *work done*. 1st. The result may be matter set in motion. 2nd. The relative position of certain portions of matter, let us say the configuration of a material system, may be altered.

In the first case we have what is termed *kinetic* energy, in the second *potential* energy. The *kinetic* energy of a moving body is proportional to the mass and the square of the velocity conjointly, and has the value $= \frac{1}{2} M v^2$, where $M =$ mass and $v =$ velocity. As an example of kinetic energy we may take a cannon ball after it has left the cannon. Its power of doing work depends on its mass and on its velocity. One of the simplest cases of *potential* energy is that of a body placed in such a position that by falling lower it acquires kinetic energy and thus has the power of doing work. For example, water in a reservoir in a high position possesses advantages which water at a lower level has not. A great deal of work may be got out of it as it falls to a lower level. A bent bow is in a similar position of advantage, and when it is discharged the energy of position of the arrow is converted into energy of motion.

I have said that work expended produces energy—kinetic or potential. Conversely, where there is kinetic or potential energy there is capacity for doing work. Thus, the cannon ball projected from the gun batters down a wall, the arrow penetrates a target, or a wound-up spring continues for days or weeks to produce kinetic energy in a clock.

Energy is often defined as the power of doing work. But we see in fact that kinetic energy, potential energy, and work, are all one and the same thing, in so far that they are measurable in a common unit. We may take to-night for our unit of work the work done in raising an imperial pound of matter through a foot against the earth's attraction at Edinburgh. Then the unit of kinetic energy, or of potential energy, is that amount of each which is produced by the expenditure of a unit of work. When any agent does 550 foot-pounds per second, *i.e.*, 33,000 foot-pounds per minute, it is said to work at the rate of a horse-power. What we mean when we talk of an engine of so many horse-power is that it is capable of doing so many times 550 foot-pounds of work per second.

Dynamical Theories of Natural Phenomena.

Every problem which deals with matter in motion and involves the consideration of three and only three fundamental elements, viz., *mass*, *space*, and *time*, and which is completely solved when we know exactly how each of these enters, is called a *dynamical* problem, and every explanation of natural phenomena depending on *mass*, *space*, and *time* alone is called a *dynamical theory*.

Hitherto I have been illustrating dynamics with systems whose motions and configurations you can see; but now I have to ask you to follow me into the far larger region of dynamics, where both motions and mechanism are as a rule invisible. The recent progress of physical science, of which you hear so much, may be summed up thus, that it is being gradually shown, and has in a great measure been already demonstrated, that the explanation of all our sensations, in other words, of all our knowledge of the external world, is purely *dynamical*. A dynamical theory is now the ideal of physical explanation. When a physicist has shown that any phenomenon is an affair of *matter*, *space*, and *time* he has done with it, he aims at no more and he hopes in all cases for no less. I may mention the cases of sound, light, and all its concomitants—heat, touch, smell. In all these cases matter, however fine or subtle, is constrained or is moving. Quite true, the mechanism of these motions is so delicate that even the most powerful microscope cannot detect it, and in many cases the physicist cannot exactly describe the matter which moves, but the evidence, although indirect, is irresistible. Energy, kinetic or potential, can be traced as a central feature in every case.

I have now to impress upon you that all these different kinds of energy are one and the same. The same in the practical sense that they are definitely convertible, so that we can say how much of one goes to make so much of the other. The classification into different kinds is a mere experimental convenience, and carries with it no essential distinction.

If we could trace completely the whole course of any physical phenomenon within a limited area it would be found that no energy has appeared spontaneously, or has been annihilated; if there is more at the end than the beginning it has come from without; if there is less it has gone from within. In other words, energy is indestructible; it may assume different forms like matter, but like matter it is *conserved*. This is the great principle of the conservation of energy, the most brilliant of the intellectual children of the nineteenth century.

It must never be forgotten in applying this law of conservation that *all* the different parts of any phenomenon must be

* The author of these lectures consents, with some reluctance, to the publication of the following rough notes, doubting whether a public much spoiled by finished productions in the way of popular lectures will be interested in them. Readers will understand that, after the introduction, what follows is merely the skeleton of a spoken lecture. The interest of the thing, so far as it may have any, is that the most prominent electrical phenomena are strung together as illustrations of the conservation of energy.

Digitized by Google

taken into account. When this can be done completely the whole of physical science will become a series of corollaries drawn from the one law of the conservation of energy. Ignorance of detail, such as I have mentioned, constrains us meantime to fill many a gap with empirical laws drawn from experience, and oftentimes even with mere assumptions; but in the main the operations of this law can be clearly traced throughout all nature. I now proceed to illustrate its operation in electrical phenomena.

Statical Electricity.

You are all aware that oppositely electrified bodies attract each other, and that like electrified bodies repel each other. In order to separate two dissimilarly electrified bodies, or to bring together two similarly electrified bodies, work must be done. In the former case the bodies have potential energy by virtue of their distance, in the latter by virtue of their proximity.

This machine (a Holtz machine) is simply an ingenious contrivance for taking advantage of the facts above mentioned for the purpose of converting work into electro-static or electro-kinetic energy as the case may be. At present the machine is excited, and Mr. Lindsay finds it much harder to drive than he would after it had stood for some time and its vital organs had lost their opposite charges. The question is what becomes of this extra work. Those of you that are sufficiently near will already be able in part to answer. Light will be seen at the combs, a hissing sound will be heard, and a peculiarly pungent odour, due to ozone, will be perceived, which represents a certain amount of potential energy of chemical separation.

But I can divert Mr. Lindsay's energy into a more striking form. I separate the terminals, the machine works for a little, accumulating electro-static energy, and then a brilliant spark passes in which this energy is transformed

1st, into the energy of sound vibrations, some part of which has been taken up by every tympanum in this room.

2nd, into the energy of luminiferous vibrations, in which again every eye in the audience has shared.

3rd, careful measurement would undoubtedly show a considerable development of heat in the air which the spark has ruptured.

I can vary this experiment in an interesting manner by increasing the capacity of the electrode of the Holtz machine. This I do by connecting with it an accumulator of statical electricity. [A Leyden jar was here charged and discharged.] You will see that more turns are required to cause the spark to pass, but the additional work thus absorbed is represented by a brighter and louder-sounding spark.

I shall next show you that the electro-static or electro-kinetic energy which represents Mr. Lindsay's work, can be reconverted into the kinetic energy of motions visible to the eye. I connect one of these parallel plates of metal with one terminal of the machine, and the other plate through the earth to the other terminal. I hang this large pith ball between the plates, and you see that when the machine is worked it vibrates so rapidly to and fro that a low musical note is heard. The energy of this motion comes from Mr. Lindsay's work, and this is, therefore, a case of electrical transmission of energy. [Then followed, as an additional illustration, the well-known experiment with the electric windmill.]

In the experiments, where a spark passes between two metallic terminals, the intervening air plays the part of an insulator, that is, of a body which stops the passage of electricity. It acts, in fact, like an elastic string, which may be stretched up to a certain point, and thus made the recipient of potential energy, but which breaks after the stretching has been carried beyond a certain limit, and then expends that energy on the fingers of the operator. Besides dry air, glass, vulcanite, gutta percha, sealing wax, shellac, silk, &c., are good insulators. If I were to connect one electrified body with another by one of these, no communication of electrical properties would take place. The result is very different, as you will see, if the connection is established by means of a metal. I connect this Leyden jar by means of a long wire with the electrode of the Holtz machine. Mr. Lindsay will do a little work for us. Now, I remove the wire, and here [jar discharged] is the proof that something has been communicated.

I now show you this Voss machine. It is in action, and sparks are passing between the electrodes. Since these sparks represent a certain amount of energy, work must be done on the moving plate of the machine. Hence there must be a reaction on the driving gear, and, therefore, if the electrification of the machine were kept up by sending a current from the Holtz machine into this one, the latter would be driven round and would become an electromotor. [This experiment was then shown, and the general principle of reversibility insisted on.]

Transfer of Electricity Along a Wire.

Let us now direct our attention to what goes on in the wire, which forms, as we said, our means of transmitting energy to a distance. This part of the subject is the most technical into which I propose to lead you in the course of these lectures, and although you may be somewhat wearied before I have done of the details through which I must conduct you, yet I am confident that, when I come to show you their applications, you will be satisfied that I have not asked you to make a vain effort.

We express the result of experiment by saying that electricity has been conducted along the wire. I could easily advance experiments to show that this something called electricity is capable of accurate measurement. Yet it is not matter, and for many reasons it would be a mistake to suppose that anything analogous to the flow of water or gas takes place along the wire. Nor is it energy, for the same quantity of electricity represents different amounts of potential energy according to circumstances. I can show you experimentally that the transmission is mediate, that is, that it can be traced all through the wire, and, what is more extraordinary still, that the phenomena accompanying transmission are to be traced in the surrounding medium, as well as in the wire. [Experiments were here shown (1) with a vacuum tube, (2) with a galvanometer, and (3) Reis's thermo-electrometer was described.]

Electromotive Force.

The tendency of electricity to pass from a body A to another B is called the electromotive force between them. It is measured by the work that would be done upon a unit of positive electricity in passing from the one to the other. Difference of pressure of fluids, and difference of temperature in thermal measurements are somewhat analogous to electromotive force. Sometimes electromotive force is expressed by talking of the potential of A and the potential of B. It is then the difference of the potentials of A and B. It is clear that there can be no electromotive force between two parts of the same conductor when it is in electrical equilibrium, for if there were there would be passage of electricity from the one part to the other. This gives us the means of measuring electromotive force by means of an instrument called an electrometer. The leading principle is that we measure electromotive force by means of the force between electrified bodies. [A schematic diagram of the working parts of a quadrant electrometer was projected on the screen and explained.]

Rate of Transference.—Current Resistance.

The rate at which the electricity flows through the wire is measured by the amount that passes any section in a second, and this amount is called the current strength, or simply the current. I have already shown you that the electric current manifests itself by magnetic action in the surrounding medium. We must now look at this action a little more closely, for upon it rests our principal means of measuring current strength. The exact law of this action is as follows: Consider only the north pole of the magnet, then the action of the current on that pole is a force perpendicular to the plane through the current and the pole, directly proportional to the strength of the current, and inversely to the distance of the pole. The action on the south pole is exactly opposite to that on the north.

We are now in a position to prove experimentally

Digitized by Google

Ohm's Law.

If we take one and the same length of wire, and cause different electromotive forces to act between its ends, we shall find the current to be proportional to the electromotive force. If we take different wires we shall find that the E.M.F. required to send a given current through them is different. If I double the length of the wire, the material and section remaining the same, the E.M.F. required is double. If I keep the length and material the same, and double the area of the section, the E.M.F. required is halved. That by which we must multiply the current in any wire to get the E.M.F. required to produce it is called the resistance of the wire. We indicate this law symbolically thus:—

$$E = C R$$

Where

E = Electromotive force.
C = Current strength.
R = Resistance.

$$R = \rho \frac{l}{s} = \rho \frac{l}{r^2}.$$

R = Resistance.
ρ = A factor differing for different materials (specific resistance).
l = Length of the wire.
s = Section of the wire.
r = Radius of the wire.

If we now reflect that the work done upon every unit of positive electricity that passes is 8 E, by our definition, and that C units of positive electricity pass every second, then we see that the amount of work done per second is $E \times C$. Expressing this result in the various units now in use we have the following important formulæ for

Work Required to Maintain a Current in a Given Wire:—

$$W = E C\ 10^7 \text{ ergs. per second.}$$
$$= \frac{E C}{746} \text{ horse-power.}$$
$$= \frac{E C}{1,356} \text{ foot pounds per second.}$$

Sources of Electromotive Force.

We have seen that every current flowing through a given wire requires a definite expenditure of energy to keep it up. Let us look for a moment at the different sources from which this energy may be drawn. In the case of the Holtz machine, Mr. Lindsay furnished us with what was needful to maintain the current. In the galvanic battery, which was until lately the ordinary means of producing a steady current, the energy of chemical separation is the source. It is easy to show that energy can be obtained by allowing two substances to combine chemically. The most familiar case is, of course, that of the combination of oxygen and carbon in the combustion of coal. If we allow sulphuric acid to combine with zinc, so as to form sulphate of zinc, we can ascertain the amount of energy given forth in the form of heat. This heat energy represents the potential energy of separation of the sulphuric acid and the zinc. Advantage of this is taken in the cell of Smee, which is one of the simplest of the galvanic batteries, and which I take on that account for illustration.

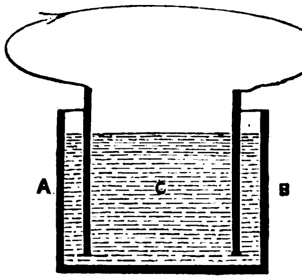

FIG. 1.

A B represents a section of such a cell, one pole of platinum, and the other a zinc plate immersed in the liquid, which is dilute sulphuric acid. The plates are joined by a copper wire, and the current flows through the wire from the platinum to the zinc. If E be the electromotive force of the cell, and C the current in the wire, the amount of energy that must be furnished per second to keep up the current is, as we have seen, E C; and hence the amount of chemical energy of separation which disappears every second owing to the formation of sulphate of zinc in the cell is E C. This energy instead of being converted immediately into heat is represented by the electro-kinetic energy of the current C.

In thermo-electric batteries two different metals (Fig. 2) are connected in circuit, and heat is applied at one junction,

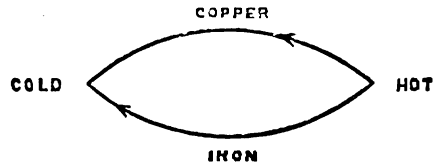

FIG. 2.—Thermo-Electric Arrangement.

while the other is kept cold, that is, heat is absorbed at one junction, but given out in a less amount at the other. The difference accounts for the energy of current.

All these sources of electro-kinetic energy are now eclipsed by the dynamo machine, which acts on the principle of electro-magnetic induction. Further discussion, however, of this must be deferred for a little until we have investigated the various ways in which we can avail ourselves of electro-kinetic energy, when it has been produced, and turn it to useful purposes. I first proceed to show you, in a variety of ways, how electro-kinetic energy can be transformed into heat, and as an extreme case into light.

[A number of experiments were performed with the aid of a dynamo machine. The lectures were given in the hall of the Industrial Museum. An A Gramme machine, belonging to Professor Tait, was at work in one of the cellars of the University, about 100 yards or so from the lecture room. The Gramme was driven by a $3\frac{1}{2}$ horse-power gas engine. A cable lent by the Brush Electric Light Company, carried through one of the windows, was used to conduct the current to the lecture table. In the engineer's workshop was another gas engine driving a Brush dynamo, giving current for the Brush arc lamps, or the Lane-Fox incandescent lamps, the current being turned into the lamps wanted by means of a switch.]

Among the experiments shown were:—

(1) The gradual heating of a yard and a half of iron wire to a bright red heat by passing through it the current from Professor Tait's A Gramme machine.

(2) A thin carbon rod was heated to a white heat, and Joules's law $H = C R^2$ explained.

(3) The Werderman semi-incandescent lamp was shown in action. In this lamp two rods of carbon impinged against a flat plate of carbon. The current dividing between the rods maintained a beautiful soft light at each point.

(4) The current was made to boil water, and cook an egg, and a calculation made as to the horse-power required to boil a kettle containing 4lb. of water in four minutes. Result about $3\frac{1}{2}$ h.-p. approximatly.

The idea of an incandescent lamp was modern, and practical lamps had been obtained only within the last two years or so. This lamp consists of a filament of carbon heated white hot in a vacuum. The difficulties met with in the construction of these lamps were first to obtain and maintain a good vacuum; second, to make and maintain good connection between the carbon filament and the conducting wires; and, thirdly, to obtain a uniform section of filament. Different inventors had used various materials from which to obtain their carbon filament. Thus, Edison used a Japanese bamboo, Swan cotton thread, Maxim cardboard, and Lane-Fox bark fibre. The success of such a lamp depended to a great extent upon its durability.

The advantages of the light were pointed out, and eight Lane-Fox lamps, specially sent down by the Brush Company, with a dynamo, were exhibited in action. They worked very well, and were much appreciated. This was the first public exhibition of incandescent lamps in Edinburgh.

Experiments were now made to show the spark at the

Digitized by Google

breaking of contact and the volatilisation of the electrode; also to show that the colour of the spark depended on the materials used, copper giving a green colour.

The spark, and then the voltaic arc, between carbons, was shown and projected on the screen. Inasmuch as the carbon gradually decreased in length when used for electrodes, inventors had to obtain means of keeping the carbons at a proper distance apart by moving them in the exact rate at which they were consumed. The results of these attempts were seen in the various arc lamps, such as that of Brush (shown), which is a pure arc lamp.

By another experiment it was shown that the electrokinetic energy of the current could be reconverted into the potential energy of chemical separation. The current of the Gramme machine was sent through a large voltameter, the separated oxygen and hydrogen filled a small bladder in a minute or two. On applying a lighted match the chemical energy was again transformed, part of it appearing in the sound of a violent explosion, which impressed the audience not a little.

ON THE GRADUATION OF GALVANOMETERS FOR THE MEASUREMENT OF ELECTROMOTIVE FORCES AND CURRENTS IN ABSOLUTE MEASURE.

BY THOMAS GRAY, B.SC., F.R.S.E.

ERRATA in the first part of this article:—Page 178, col. 1, line 10, for "to" read "so," and for "single" read "simple." Page 178, col. 1, line 16, after "necessary" insert "corrections." Page 178, col. 1, line 36, for "vertical" read "vertically." Page 178, col. 2, last line, in the formula, for "8" read $\frac{8}{3}$.

(CONTINUED FROM PAGE 178.)

We have next to consider how we can best take into account the form and dimensions of the coil. For most instruments as supplied by the makers it is impossible to determine by calculation with any degree of accuracy the deflection of the needle which would be produced by a given current sent through the coil. Hence, for the purpose of graduating galvanometers in absolute measure we find it necessary to construct a coil of such form and dimensions as we can easily measure with accuracy. For this purpose there is, perhaps, nothing better than some modification of the old form of tangent galvanometer with a coil of large radius. In making up such an instrument to be used as a standard the following points ought to be carefully attended to. The wire of the coil ought to be sufficiently thick to prevent any risk of damage, due to heating, from the strongest current that is likely to be sent through it. The coil should form a circular ring, the diameter of which is great compared with its other linear dimensions. For convenience and accuracy of construction it is best to make the ring of rectangular section. The total length and resistance of the wire should be accurately measured before the coil is wound, and its resistance again measured after the winding has been performed, and the result of this latter measurement compared with the former. The measurement of the length of the wire is important, as this enters into the subsequent calculations. If the resistance before and after winding agree, the wire may be assumed to be properly insulated, and not to have sensibly stretched during the operation of winding; but if it be less after than it was before the coil must be rejected as untrustworthy. If it is greater the wire must have been stretched by the winding, and therefore the number of turns and the measured internal and external diameters of the ring have to be depended upon in the subsequent calculations. It is well to stretch the wire slightly before winding it in order to harden it, and thus as much as possible avoid any such change of length. The number of turns must also be determined, and the diameters should be measured in order to check the previous measurement of length. The mean radius is most accurately obtained by dividing the length by $2\pi n$ where n is the number of turns. The breadth and depth of the rectangular section have also to be measured, if great accuracy is aimed at in the experiments for which the instrument is intended. The needle of this instrument should consist of one short magnet, or a system of short magnets suspended by a silk fibre, with the centre of the magnetic axis of the magnet, or system of magnets, as exactly as possible in the centre, of the ring, and in its medial plane. This needle should either have a mirror or a light horizontal index five or six inches in length, rigidly attached to it for the purpose of allowing its deflections to be observed with accuracy. These deflections may be observed either in degrees or in tangents by means of a circular scale divided to degrees or tangents placed under the outer end of the index. The centre of this circular scale must be placed exactly under the centre of the magnetic axis of the needles. In order to prevent errors from currents of air or parallax the needle and index should be enclosed in an air-tight box with a glass top and mirror bottom. While observations are being made the mirror should be level, and the eye of the observer should be so placed that the index covers its image in the mirror. It is convenient for purposes of observation to have the index fixed with its length at right angles to the axis of the needle; and, assuming that the line joining the divisions 0° and 180°, or the radius passing through the zero of the scale is placed accurately at right angles to the plane of the coil, it is necessary, in order that the instrument should give equal deflections on the two sides of zero, that the axis of the needle and the line through the suspending fibre and the point of the index should be exactly at right angles to each other. To test whether the centre of the magnetic axis is exactly above the centre of the scale, draw three radial lines, one through the zero, and the other two making an angle of about 45° on opposite sides of this, and observe whether the needle, by being deflected, can be brought into parallelism with each of these lines. To test whether the index is at right angles to the magnetic axis of the needle draw two lines on a piece of cardboard, and placing it under a long thin magnet suspended by a silk fibre, turn it until one of the lines is exactly parallel to the line joining the poles of the magnet. Then suspend the needle and index over the paper, and observe whether the index sets itself parallel to the other line. That the radial line through the zero of the scale is at right angles to the plane of the coil may be tested either by sending the same current through the coil in opposite directions, and observing whether the deflections are equal on the two sides of zero, or by suspending a long thin needle over the line (the coil being in this case at right angles to the magnetic meridian), and observing whether a current sent through the coil produces any deflection. This needle should project equal distances on the two sides of the coil, because if this is not attended to there will be a tendency to motion of translation when the current is sent through the coil. The suspending fibre should, of course, be attached to the needle at a point vertically above the centre of the magnetic axis, so as to make the needle stable in a horizontal position, the centre of inertia of the system being supposed in the line of suspension when the index is horizontal. When a mirror is used instead of an index the coil is placed in the magnetic meridian, and therefore parallel to the axis of the needle, by observing when the deflections due to the same strength of current are equal on the two sides of zero.

Let us suppose that we have such an instrument as that just described, and let the mean radius of the coil be R, the breadth of the ring $2b$, and its depth $2d$, and suppose a current of C units per unit area of section of the coil to be sent through it. (By a current of C units per unit area of section of the coil is meant such a current that if its strength were multiplied by the number of turns per unit area of section the product would be C. The current is here measured according to the "absolute" system electro-magnetically, that is to say, unit current is that which, circulating in a circular arc of unit length and of unit radius, would act on a unit magnetic pole placed at the centre with unit force. A unit magnetic pole is that pole which, placed at unit distance from an equal and similar pole, would be repelled with unit force.) Then the magnetic force due to the current flowing through an element $dx\,dy$ of the section on a unit pole placed at the

Digitized by Google

centre of the coil will be $f_1 = 2\pi C \frac{dx\,dy}{x^2+y^2}$, where the origin of co-ordinates is at the centre of the coil. The component of this force tending to move the pole in a horizontal line at right angles to the plane of the coil is

$$f_2 = 2\pi C \frac{y\,dx\,dy}{(x^2+y^2)^{\frac{3}{2}}}.$$

Hence we have for the total horizontal force on the pole

$$F = 4\pi C \int_0^b \int_{R-d}^{R+d} \frac{y\,dx\,dy}{(x^2+y^2)^{\frac{3}{2}}}.$$

Integrating we find

$$F = 4\pi C b \int_{R+d}^{R+d} \frac{dy}{(b^2+y^2)^{\frac{1}{2}}}$$

$$= 4\pi C b \log \frac{R+d+\sqrt{(R+d)^2+b^2}}{R-d+\sqrt{(R-d)^2+b^2}}. \quad . \quad (3)$$

Now, if a be the deflection of the needle caused by this current, we have from the equation of equilibrium

$$F = H \tan. a,$$

and therefore

$$H \tan\, a = 4\pi C b \log \frac{R+d+\sqrt{(R+d)^2+b^2}}{R-d+\sqrt{(R-d)^2+b^2}},$$

from which we obtain

$$C = \frac{H \tan. a}{4\pi b \log \frac{R+d+\sqrt{(R+d)^2+b^2}}{R-d+\sqrt{(R-d)^2+b^2}}}. \quad . \quad (4)$$

When b and d are small compared with R, this equation becomes very nearly

$$C_0 = \frac{H R \tan. a}{2\pi n} = \frac{H R^2 \tan. a}{l}, \quad . \quad . \quad (5)$$

where l is the total length of wire in the coil and C_0 the strength of the current flowing through the circuit, or, which is the same thing, $\frac{4bd}{n}C$.

The error due to using equation (5) instead of the exact equation as deduced from equation (4) is only about $\frac{1}{20}$ per cent, when b and d are each $\frac{1}{10}$ of R, and, as this is a larger value of b and d than would in most cases be adopted, the approximate formula may be taken as giving the value of the current to a closer degree of approximation than can be attained in the observations. We will, therefore, assume in our calculations that equation (5) is sufficiently correct for our purpose.

To find the constant for reducing the indications of a galvanometer to amperes let the instrument be joined in series with a standard galvanometer, a battery, and such resistance as may suffice to bring the deflection to a convenient amount. Observe that the instruments indicate zero when no current is flowing (it is well, when observing the zero of a high resistance galvanometer, to put a short wire across its terminals in case there should be any thermal or other electromotive force in the coil), then close the circuit, and observe simultaneously the deflection on the two instruments; then reverse the current, and again observe the deflection on the two instruments. Let a be the mean deflection on the standard, and a' that on the instrument being tested. From the standard galvanometer we have for the current C in absolute measure

$$C = \frac{H R^2 \tan. a}{l},$$

and since one ampere is $\frac{1}{10}$ of a C.-G.-S. unit of current, if C_a denote the current in amperes,

$$C_a = \frac{10 H R^2 \tan. a}{l}. \quad . \quad . \quad . \quad . \quad (6)$$

Now, if the value of H is the same for both instruments we have from the galvanometer which is being tested

$$C_a = G H \tan. a',$$

where G is the constant of the galvanometer when placed in a magnetic field of unit intensity.

Therefore, from (6) we have

$$G = \frac{10 R^2}{l} \frac{\tan. a}{\tan. a'}. \quad . \quad . \quad . \quad . \quad . \quad (7)$$

It is assumed here that the galvanometers are placed in a uniform field of force, but it must be remembered that it is difficult to obtain this in most laboratories not specially constructed for electrical experiments. In an ordinary room the force may vary as much as 10 per cent. between two points two or three yards apart, the variation being caused by iron in the structure of the building. We require, therefore, not only the absolute force at the place of the standard galvanometer but we require also the force at the other instrument. The ratio of the forces at the two places may be determined by vibrating a magnet in the way described for determining H, and deducing its value by the equation,

$$\frac{H}{H'} = \frac{T'^2}{T^2},$$

where H and H' are the forces at the places at which the periods are T and T' respectively. The ratio may also be determined by placing a galvanometer first in the one and then in the other position, and observing the deflection produced by the same current in the two cases. In that case we have

$$\frac{H}{H'} = \frac{\tan. a'}{\tan. a}.$$

For an instrument which is to be used always in one position and under the earth's field alone this is all that is necessary. But for many practical purposes the instrument requires to be moved from place to place, and, besides, requires the field of force to be much more intense than that of the earth in order to keep its indications within the range of the scale, and to prevent disturbances from magnets or from iron in the neighbourhood. The field is generally intensified by placing a permanent magnet near the needle in such a manner as to produce at the needle a magnetic field parallel to the plane of the coil. This field magnet is in the best position when the centre of its magnetic axis coincides with the centre of the magnetic axis of the needle. Except in the case of an instrument to be used always in the same position and under the influence of the earth's field alone, it will be found most convenient to know the constant of the coil for a field the intensity of which is unity. When this constant is once known a standard galvanometer is not again required for the adjustment of the constant of the instrument, all that is required being the intensity of the magnetic field in which the needle is placed. The determination of the constant of a galvanometer for unit field does not involve the determination of the absolute intensity of the field either at the place where the standard galvanometer or the one to be tested is placed. The ratio of the intensities at the two places, however, must be known, and hence the desirability of making the tests at a place where the ratio is unity. When this ratio is $\frac{H}{H'}$, equation (7) becomes

$$G = \frac{10 R^2}{l} \cdot \frac{H \tan. a}{H' \tan. a'}. \quad . \quad . \quad . \quad . \quad (9)$$

When the sensibilities of the two instruments are so different as to render the method of comparison here described unsuitable, the instrument which is most sensitive may be shunted by a known resistance. Should the instrument to be shunted have a very small resistance it may be advisable to add some resistance external to it. This resistance is to be treated as part of the coil when shunting the instrument. Let C_a and C'_a be the current flowing through the unshunted and shunted instruments respec-

Digitized by Google

tively, R_1 the resistance of the coil and added resistance and R_2 the resistance of the shunt, then

$$C_a = C'_a \frac{R_1 + R_2}{R_2}.$$

A galvanometer, the coil of which has a high resistance, forms a very convenient instrument for the determination of the difference of potential between two points of a circuit. Such an instrument has been called by Sir William Thomson a potential galvanometer. When the instrument is to be used as a potential galvanometer, the constant G requires to be multiplied by the resistance of the coil in ohms, as will appear from the following considerations. We have for the current flowing through the coil

$$C_a = G\,H \tan. a'.$$

and by Ohm's law, if R be the resistance of the coil in ohms, and E the difference of potential between its ends in volts,

$$E = C_a' R = G\,R\,H \tan. a'.$$

Hence, if G_v be the co-efficient for volts,

$$G_v = G\,R.$$

The methods of determining the co-efficient for volts are the same as those which may be employed for the determination of the co-efficient for amperes, as, for instance, that already described. The mode of joining up the instruments illustrated in Fig. 2 will be convenient for many purposes, especially where potential galvanometers are being tested. The standard galvanometer G is joined in series with a

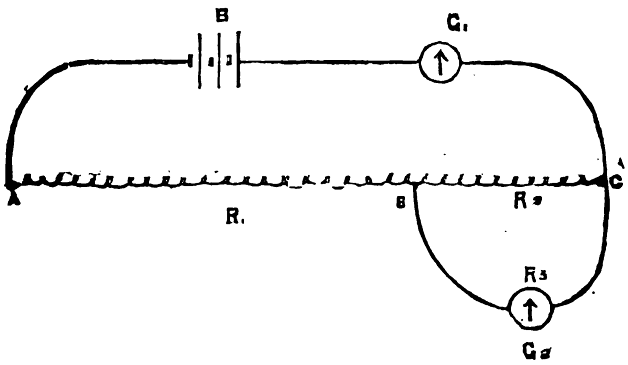

FIG. 2.

battery, B, and a resistance, $R_1 + R_2$, while the galvanometer G_2 is joined to the points B and C, so as to form a shunt on the resistance R_2. The battery B and the resistance R_1 and R_2 are to be adjusted to give a convenient deflection on G_1. It may be remarked that the best deflection is 45°, this being the deflection which gives the least error due to a given constant error in the observation of the deflection. If a be the deflection due to any current, and $\delta\,a$ the probable error of observation, the percentage error in the estimation of the current is proportional to

$$\frac{\tan.(a + \delta\,a) - \tan.a}{\tan.a},$$

or nearly to

$$\frac{\delta\,a\,(1 - \tan.^2 a)}{\tan.a\,(1 + \tan.^2 a\,\delta\,a)},$$

which is zero when a is 45°. Let C_a be the current in amperes flowing through the galvanometer G_1, then the current flowing through G_2 is $C_a \frac{R_2}{R_2 + R_3}$, and hence we have

$$C_a \frac{R_2}{R_2 + R_3} = G\,H \tan. a',$$

or

$$G = \frac{C_a R_2}{(R_2 + R_3)\,H \tan. a'} = \text{co-efficient for amperes.}$$

The co-efficient for volts is

$$G\,R_3 = \frac{C_a R_2 R_3}{(R_2 + R_3)\,H \tan. a}.$$

Now, if R_3 be great compared with R_2, this equation may be written $G_v = \frac{C_a R_2}{H \tan. a}$, that is to say, the difference of potential between B and C may be taken to be the same as if the circuit of G_2 were broken. When R_2 is less than $\frac{1}{1000}$ of R_3, this method is convenient and sufficiently accurate.

Next let us consider how the intensity of the magnetic field produced by a permanent magnet may be determined. Suppose an arrangement similar to that in Fig. 2 to be made, omitting the standard galvanometer G_1, let the resistance between B and C be adjusted so as to give a convenient deflection on G_2, when the earth's magnetic field alone is used, and again, when the magnet is placed in position on the instrument. Let the resistances in the two cases be R_1 and R_2, and let R_3 be the resistance of the galvanometer, R the total resistance in the battery circuit when the galvanometer circuit is broken, and E the E.M.F. of the battery. The current through the galvanometer in the first case will be

$$\frac{E\,R_1}{(R - R_1)\,(R_1 + R_3) + R_1 R_3},$$

and in the second case

$$\frac{E\,R_2}{(R - R_2)\,(R_2 + R_3) + R_2 R_3}.$$

Let the intensities of the magnetic field be H and H′, and let the deflections be a and a' in the two cases, then

$$\frac{H \tan. a}{H' \tan. a'} = \frac{R_1\{(R - R_2)\,(R_2 + R_3) + R_2 R_3\}}{R_2\{(R - R_1)\,(R_1 + R_3) + R_1 R_3\}},$$

and therefore

$$H' = \frac{H \tan. a}{\tan. a'} \times \frac{R_2\{(R - R_1)\,(R_1 + R_3) + R_1 R_3\}}{R_1\{(R - R_2)\,(R_2 + R_3) + R_2 R_3\}}. \quad (10)$$

When the resistance of the galvanometer is great compared with the resistance of the battery, or when its sensibility is sufficient to allow resistance to be added to its circuit, the formula can be simplified by neglecting the battery resistance, and making $R_2 = R$, we then have the potential between A and C equal to the full potential of the battery, or

$$E = G_v\,H' \tan. a',$$

and the potential between B and C

$$E_1 = G_v\,H \tan. a = \frac{E\,R_1}{R + R_1}.$$

Substituting for E, we get

$$G_v\,H \tan. a = \frac{R_1}{R + R_1} G_v\,H' \tan. a',$$

$$\therefore H' = \frac{H \tan. a}{\tan. a'} \cdot \frac{R + R_1}{R_1}. \quad (11)$$

It must be remembered that H′ represents the sum of the intensities of the fields produced by the earth and the magnet, and hence, that if H_m be the intensity of the field produced by the magnet alone, then $H_m = H' - H$, and, therefore

$$H_m = H \frac{R \tan. a + R_1 (\tan. a - \tan. a')}{R_1 \tan. a'}. \quad (12)$$

A similar equation for H_m may be deduced from equation (10), but it is generally simpler to use equations (10) and (11) and subtract H from the result.

When, as is the case with Thomson's new current and potential galvanometers, the sensibility can be changed without changing the intensity of the field we may adopt the following simple method of comparing the intensity of the field produced by the magnet with that of the earth. Join up the galvanometer in circuit with a battery capable of giving a constant current, and adjust the sensibility of the instrument until a convenient deflection is obtained with the earth's field alone; let a be this deflection. Next place the magnet in position and change the sensibility until a similar deflection is obtained; let a' be this deflection, and let S be

Digitized by Google

the ratio of the sensibility in the first to that in the second case, then

$$\frac{\tan.\alpha}{\tan.\alpha'}=\frac{H'}{SH}\text{, and, therefore, }H'=SH\frac{\tan.\alpha}{\tan.\alpha'},$$

or,

$$H_m=H'-H=\frac{SH\tan.\alpha-\tan.\alpha'}{\tan.\alpha'}. \quad . \quad (13)$$

Various modifications of the methods here described will at once suggest themselves, and in the case of the magnet constants several purely magnetic methods might be employed; but it is generally better to determine the constant of the magnet when in position on the galvanometer, and when possible by means of the galvanometer itself.

Graduation by Electrolysis.

The electro-chemical equivalents of most of the metals have been carefully determined and tabulated, and hence we may avoid to a great extent the labour entailed by the method above described by taking advantage of these tables of equivalents. The following brief indication of the mode of proceeding to take advantage of these tables will probably be sufficient for most purposes, but much useful information on the mode of obtaining good deposits can be obtained from any good book on electro-plating.

Make up a strong neutral solution of pure copper sulphate and pour it into a suitable vessel to act as a plating bath; an ordinary beaker will generally do. Cut two plates for electrodes out of thin sheet copper of such a size that the density of the current between them will be about $\frac{1}{50}$ of an ampere or less; that is to say, the area of the plate in square centimetres should be about 50 times the number of amperes of current in the circuit. Clean the plates carefully by polishing and washing first with acidulated and then with clean water. Put some distinguishing mark on them, and then weigh them accurately on a sensitive balance. Place them in the liquid, with their planes parallel and facing each other, at a distance of about one or two centimetres apart, and join up this cell in series with the galvanometer to be tested and a battery equal to about two or three Daniell's elements. Observe the time when the circuit is closed, and take care that it is not broken or reversed during the experiment. Take a reading of the galvanometer deflection, say half a minute after the circuit is closed, and then at regular intervals during the experiment. If the current is nearly constant the intervals between the readings may be several minutes, but if it is variable frequent readings must be taken. The current should be allowed to flow for such a length of time that the copper deposited can be accurately weighed with the balance at disposal, it may extend from fifteen minutes to an hour or more according to the strength of the current and the sensibility of the balance. Note the time when the circuit is broken, and then remove the plates carefully from the solution, and wash the one on which the copper has been deposited in clean water. Great care has to be taken, especially when the amount of copper deposited is small, to avoid error due to imperfect washing or drying of the plate, and also that none of the deposited copper is removed in the operation. The water in which the plate is washed, as well as the solution, should be carefully examined for metallic copper, and if any is found the experiment should be repeated. Weigh the plate and subtract the weight which it had at the beginning of the experiment, the difference is the weight of copper deposited. From this we obtain the value of the galvanometer constant in the following manner:—One coulomb of electricity deposits very nearly ·00326 of a gramme of copper from a solution of sulphate of copper; hence the number of grammes deposited, divided by ·00326, gives the number of coulombs, while this number, divided by the time in seconds that the current was flowing, gives the mean current in amperes. That is, if w be weight of copper deposited, and t the time in seconds,

$$C_a=\frac{w}{t}\,\frac{1}{\cdot 00326}.$$

Now, assuming as before that we are using a tangent galvanometer, we may find the mean tangent of the deflection by finding the sum of the means of the tangents of each successive pair of readings multiplied by the interval between them, and dividing the result by the total time that the current flowed; or we may make the time and tangents of deflections abscissæ and ordinates of a curve, and find the area enclosed by the curve, and the axes of co-ordinates by any of the approximate methods employed for that purpose. Let the mean tangent so found be denoted by tan. α, and we have the equation

$$C_a=G\tan.\alpha$$

for the determination of G, the co-efficient for amperes of the instrument in the actual magnetic field employed during the experiment. If the co-efficient for volts be required it may be obtained from this by multiplying by the resistance of the galvanometer.

When determining galvanometer constants by this method it is important that the whole current passing through the circuit be sent through the electrolytic cell, as polarisation prevents any method in which shunts are used from being reliable. It may be remarked also that this method is not very well adapted for high resistance galvanometers unless they be sufficiently sensitive to admit of their being strongly shunted during the experiment, because of the feeble current which can be sent through such instruments. If a high resistance galvanometer be tested by shunting it so as to lower the resistance in the circuit care must be taken that the resistance of the shunt is not changed by heating during the experiment.

ANTOINE BREGUET.

Our contemporary, *La Nature*, announces the death, from heart disease, on the 8th inst., of M. Antoine Breguet, well known in electrical circles in Paris. M. Breguet was only 32 years old when he died, having been born in Paris on the 26th January, 1851. To complete his education he entered the Polytechnic School in 1872, and on leaving this at once entered the firm of Breguet as electrical engineer.

During this period (says our contemporary) he published essays on telephony and electrical machines. He made one notable contribution to the *Annales de Chimie et de Physique* on the theory of the Gramme machine, an essay which was marked by great simplicity and replete with original ideas. At the end of 1877 Antoine Breguet married. A little later, in 1880, he accepted the management of the *Révue Scientifique*, in common with his friend, M. Richet, an able physiologist and writer.

In 1881 Antoine Breguet took an important part in the organisation of the Electric Exhibition, as head of the department for placing and arranging the exhibits. He worked in this capacity with great zeal and activity, and exhibitors invariably found him most willing to oblige. Antoine Breguet, by his intelligent and earnest assistance to M. George Berger, contributed greatly to the success of the Exhibition. It was he who originated the happy idea of establishing telephonic auditoriums at the Palais de L'Industrie in connection with the Opera. He was nominated a delegate to the Congress of Electricians by the management of the Exhibition, and was rewarded for his labours at these two international gatherings by the Cross of Chevalier of the Legion of Honour.

At the beginning of the present year the firm of Breguet was formed into a company, and Antoine Breguet assumed the management, with the title of managing director. Before becoming manager of the *Révue Scientifique* Antoine Breguet was a member of the staff of *La Nature* from the year 1875 to 1878. He leaves a young wife and three children, and friends who sincerely mourn his sudden loss.

Business Notice.—We are informed that the businesses of Mr. W. F. Dennis, also Messrs. W. F. Dennis and A. Dennis, wire merchants, &c., of 101, Leadenhall-street, E.C., hitherto carried on under the style of Dennis and Dennis, will be amalgamated, and will hereafter be carried on under the style of W. F. Dennis and Co.

ELECTRICITY AND WAR.

That nothing is so certain as the unexpected has once again been demonstrated in the old familiar way. Notwithstanding the telegraph and the guarantees of peace which were supposed to follow in its train, war, for the hundredth time, has contrived to take us by surprise. Probably not one of the civilians who went down to Chatham the other day to witness the performances of electricity in the interesting pastime of mimic warfare had pictured to himself even the possibility of such things happening in real earnest. Yet at about the self-same hour, when earthworks were being blown up for the amusement of our telegraph engineers, just to show how it could be done should ever occasion arise, similar explosions were rending the air elsewhere, carrying with them skywards the fragments of some hundreds or thousands of hapless mortals who had persisted in the belief that shot and shell are the only arguments worth listening to. That belief is not confined to the Egyptians, and it is fortunate for us all that the military instinct of every nation finds its outlet in foreseeing and providing for contingencies which the civil professions are slow to apprehend. But for the painstaking wisdom of those very officials and their associates who gave us a day's entertainment at one of England's greatest arsenals, England might now have been, not only surprised, but unprepared.

Over and above the telegraph, electricity has of late years played an important part in the operations of war. Some people prefer to say that those deadly ingenuities, the electrical torpedo, electrical mining, electrical volley firing, and the like, all tend to avert war. Certain it is they add to the horrors of war, and if only the enemy would consent to be frightened by them beforehand, undoubtedly there would be no occasion for war. But we have not arrived at that stage yet awhile, and for the present we must be content with at least shortening their duration, though we cannot prevent the outbreak of hostilities.

That we cannot by any yet known mode of reasoning, or any sufficiently overmastering form of armament, prevent war, is made plain to us with ever painful recurrency, and the lesson we ought to learn from this fact is to be always prepared for it. By being prepared for it in this relation we, of course, mean being well provided for it. We observe, therefore, with much satisfaction, that our fleet before Alexandria is amply equipped with electric lighting appliances. This means that during the last interval of peace our naval authorities have instituted and perfected experimental electric lighting to a degree enabling them to utilise it promptly and efficiently when the time came for using it. The time, as sure as ever, did speedily come; and here we have the electric arc piercing the darkness of treacherous night, prying into the stealthy operations of the foe on land, and keeping off all sinister movements by water. It would appear, also, that it has been used for signalling purposes, and it is obvious how readily this may be done at distances many times greater than those it was required to penetrate before the doomed city of Alexandria. A dot and dash message might, we imagine, be read far beyond mast-head level, if flashed upwards instead of horizontally. All this speaks well for the electric light as an adjunct of war, but it also reflects the highest credit on the wisdom of our naval and military authorities.

Of the immense service rendered us by the cable operations at this juncture we need hardly add one word to what has already been freely confessed by the daily Press. But we can remember the time when co-operation such as that which just now seems so natural would have been all but impracticable. Now we hear of the fleet admiral "ordering" the telegraph ship nearer in shore. Not so many years ago the chances are he would have "ordered it off." Perhaps in his heart he wishes it was far away, and that Downing-street were not made quite so near; but if personal responsibility is no longer to prevail in the leaders of our armies and our navies, the closer they can be brought to the men who are responsible, the better, obviously, for all parties.

In spite, however, of the general excellency of the arrangements, and our certainty that all was done that science had yet enabled us to do, one little shortcoming could hardly fail to be noticed in the events of last Tuesday week. The "Chiltern" cable ship was but a comparatively short distance from the fighting ships, yet communication was difficult and slow—occupying, it would seem, as long a time as to bridge over the 2,000 miles separating her from London. This is not as it should be; and the most pressing invention needed for naval warfare is a ready means of electrically telegraphing between ship and ship. The discovery made by an officer of the Royal Engineers some time ago naturally recurs to us in this connection. He found that by means of the telephone, signalling with a Morse key could be very well heard, though the conducting wire was severed and far apart,

Digitized by Google

when the ground was wet, or the ends were in a river. Mr. McEvoy's application of Professor Hughes's induction balance principle to the detection of submarine torpedoes has also a bearing on this desideratum. Even dismissing these perhaps too speculative hints, and coming to safer ground, we cannot help thinking that what the military telegraph corps has done for its department might conceivably be done for the navy. A floating drum bearing a light cable is not, one would imagine, an impossible device, especially to any one who has seen silk unwound from a cocoon in water. The cocoon, it is true, has but one end free; but to the heroic inventor this is a mere detail.

Speaking of light cables we are reminded how useful would have been even a temporary means of communication of that sort along the Suez Canal at this moment. The high road to India is what we are at present—if we except Ireland—most concerned with, and yet when the admiral of our fleet had greatest need of knowing the condition of that route, a gap of some 150 miles intervened between him and it, and even then he had no means of ascertaining what might be going on in the midst of it or at the other end. But here, probab ly statesmen, and not the officials we have been commending, are the people in fault. The establishment of telegraphic communication along a marvellous but somewhat ticklish maritime pathway is greatly to be desired, and possibly this fact may be brought home convincingly by our present troubles in Egypt, as was the much-needed cable to South Africa by hostilities in that quarter.

THE CRYSTAL PALACE EXHIBITION.

Post Office Exhibits.

(CONTINUED FROM PAGE 199.)

Last week an unfortunate error occurred in Fig. 11. The wire connecting zinc to the left hand relay should have been joined to line only. In Fig. 12, also, the draughtsman has represented a hand working the key on the right, whereas only the key on the left side of the diagram is supposed to be working.

By winding the bobbins of the polarised relay with two sets of wires, as already described, duplex transmission becomes practicable on long lines. Instead of the batteries being joined up, as in the preceding illustration, they may have like poles to earth and to the key. In this case each station would receive a signal during the simultaneous depression of the keys, in consequence of the antagonistic electric forces in the real line reducing the electro-magnetic effects of that branch to insignificance, while another portion of the current from the home battery acts vigorously upon the artificial line R. As duplex telegraphy can be maintained whether the distant batteries assist or oppose each other, the method becomes applicable to the double current system previously noticed. Fig. 14 displays a complete double current duplex sounder set of apparatus as adopted by the Post Office. A is the key, B relay, C galvanometer, D sounder, E rheostat, F condenser, and G switch. The condenser contains sheets of tin foil and paraffined paper alternately separated. The tin foil sheets are divided into two groups, and connected up, as seen in Fig. 15, where the spaces between the lines represent paraffined paper. Without a condenser in-

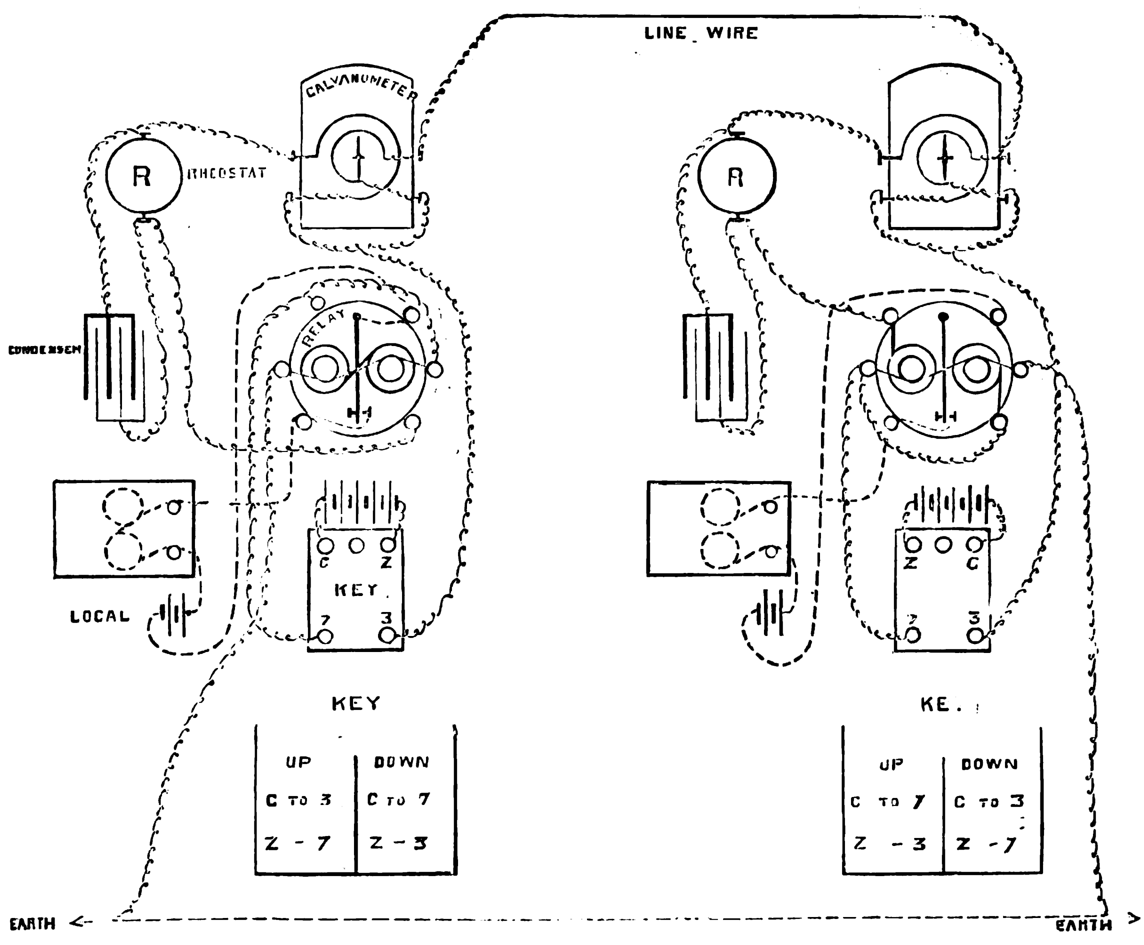

FIG. 15.—Plan of Double Current Duplex Circuit.

terruptions would occur while receiving, due to the back rush of electricity from the line wire through the relay; but by causing the electrostatic induction of the condenser to equal that on the line, the opposing and simultaneous discharge from both keeps the balance of relay perfect, and thus avoids interference. Some of the brass pegs represented in F, Fig. 14, enable the operator to vary the electrostatic capacity of the condenser according to the state of the line. The arm of switch G makes the system simplex or duplex. The galvanometer C is wound differentially, like the relay, *i.e.*, two lengths of wire having the same resistance. This facilitates easy balancing of relay by adjusting the rheostat as the key is actuated, until the needle remains motionless. Fig. 15 is one example of a double current duplex circuit.

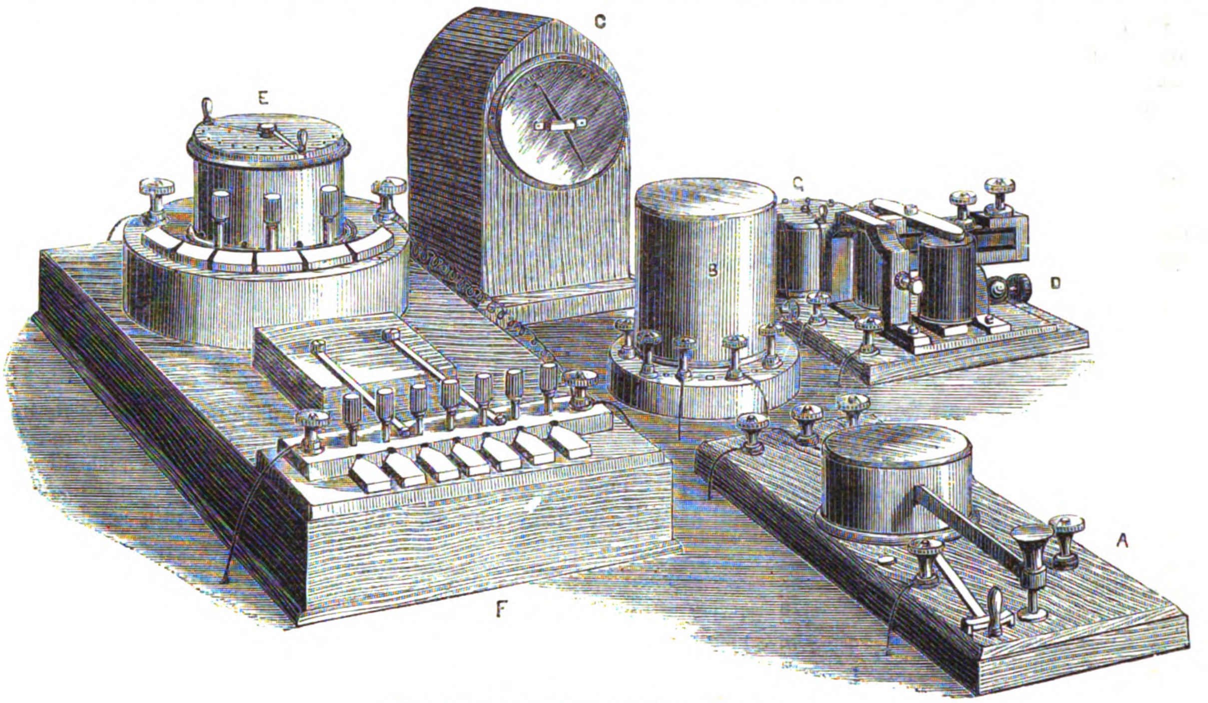

Fig. 14.—Double Current Duplex Sounder.

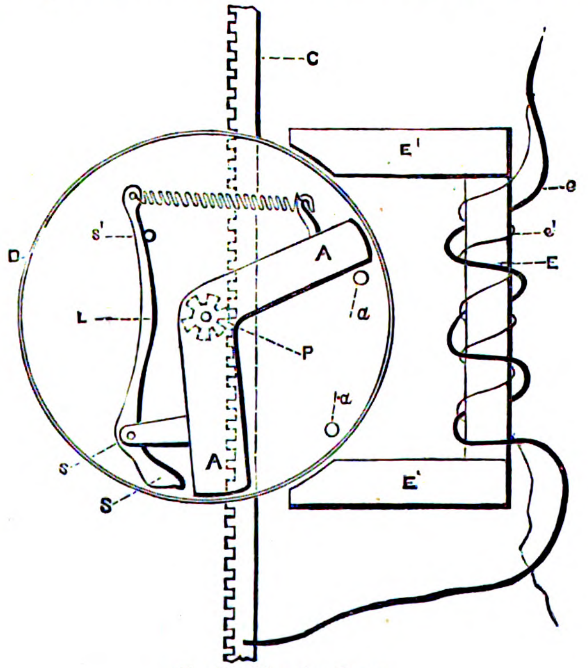
(TO BE CONTINUED.)

THE DIAMOND ARC LAMP.

This lamp, which is now being exhibited at 374, Euston-road, is made from the design of Mr. C. D. Haskins, of New York, a gentleman well known in electrical circles not only in America but also on this side the Atlantic. As in most of the modern lamps, the upper carbon descends by gravity, its motion being controlled by an electro-magnet. The accompanying diagram shows the mechanism of the lamp. The upper carbon holder is attached to the rack C. This rack gears into a pinion, P, fastened to the centre of the disc D, which disc rotates by the descent of the carbon. Instead of the rack and pinion, which are preferred, a cord and pulley or other equivalent arrangement may be used. To control the downward movement of the carbon holder a brake is applied to the rim of the disc, and as the disc may be of a fairly large size the power requisite to check its motion and resist the weight of the carbon holder may be very small. The brake is shown in the figure at the foot S of the bent lever L, pivoted at *s* on an arm of the armature A A.



The Haskins Arc Lamp.

This armature is pivoted at the centre of the disc D, about which it freely swings under the action of the varying actions of the poles E′ E′ of the electro-magnet E. The core of E is wound with two coils of wire, the priminary *e* of thick wire traversed by the main current, and a secondary *e*′ of fine wire to act as a shunt.

When the carbons are together before starting the light the greater part of the current goes through coil *e*. The armature A A is attracted, carrying with it the brake S, which clamps against the rim of the disc D. Any further motion of the armature then turns the disc and raises the upper carbon establishing the arc. When the main coil current weakens by the lengthening of the arc, the armature swings away from the magnet by the action of gravity, and in doing so lowers the carbon to a slight extent. When it reaches the position in which the upper end of the lever L bears against the pin *s*′, the brake S is released and the carbon is free to slide downward. These movements under normal conditions are small, the parts being so arranged as just to allow the carbon to descend at the proper rate. The lamp is said to adjust itself to the current, and to burn well with either a weak or a strong current, in the one case the carbons being closer together, and being, therefore, a shorter arc than in the other case. It will be seen that the parts of this lamp are few, and thus it offers the great advantage of simplicity. When we saw the lamp is was burning steadily.

CORRESPONDENCE.

DYNAMO MACHINES AND HELICAL FORCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you allow me to call attention to the errors and confusion of the article on dynamo machines, &c., in your last issue, on page 176. And, first, I would like to know what kind of machine is the "Saxton Commutator," and when was it patented? By the "Gramme Commutator" the writer, no doubt, means the Gramme dividing machine—but why doesn't he say so? Again, he puts the Siemens as a direct descendant of the Gramme, and the Brush he inserts twice over. As for the rest, it is scarcely necessary to do more than point out that he—or the engraver—is unable even to spell the names of four of the few other machines he thinks fit to mention.

It is a pleasure to turn from these laboured articles to the fresh and fascinating subject treated so eloquently by Dr. Shettle on pages 181, 182, and 183, the ever fruitful theme, "What is Electricity? Temperature." Many times have I been struck with the action of helical forces in nature, but never more powerfully than by the beautiful and lucid illustration of the blind cords in article X. The quadrillions of tons of force screwing themselves down from the sun upon the earth, and then being discharged up again from the poles as a mighty reaction, and the evolution of the laws of motion through the helical vortices generated when the sun's helical force gets entangled in the earth's helical reaction, as developed in sections 17 to 20, form a conception never equalled since the publication of the "Principia."

The universality of the action of helical forces and the vortices produced by helical reaction may be illustrated in so many striking ways that I may be pardoned for suggesting one that I noticed at a restaurant the other day, where by an application of helical force a liquor was extracted from a glass vessel which could not possibly have been extracted in any other way, and the helical reaction lying dormant in the liquid was not yet discharged (this was the important observation) till it had entered a living organism. But, sir, a still more astounding discovery has rewarded me since then. I have discovered a liquor whose helical reaction is so great that it can extract its own cork. No external helical appliances are necessary; in fact, it exerts a negative helical force itself, and wires have to restrain it—wires which conduct electricity. The liquor is expensive, and, I believe, is a monopoly of a Mr. Heidseick, but if he or any of your correspondents would send me some to try I should be able to investigate whether the latent and organically developed portion of the helical reaction is as great as I venture to predict it will be.—Yours, &c.

CHARLES JONES.

Science Chambers, Upper Holloway.

[The engraver was guilty of the errors which appeared in the table adversely criticised by our correspondent, mistaking, or rather unheeding, his instructions not to finish the block before the drawing was corrected.—Ed. *E.*]

DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to a letter in your publication of the 15th inst., signed "Wonderer," the most likely cause of the trouble is that the lamps are out of adjustment, and that occasionally one or the other breaks arc; a load is consequently taken off the engine, and if driving the dynamos constitutes any considerable proportion of its work, it probably "runs away" more or less with the machine driving the other lamp, the latter brightening up in consequence.

Dynamo machines, however, should never be fastened upon iron bed plates; these should be of wood. The presence of any iron other than parts of the machine itself produces a redistribution of the magnetic field, which will necessarily influence the working of the machine. The sheet asbestos used to avoid actual contact only slightly moderates the effect by removing the iron a little further (probably a very little) away from the machine than it otherwise would be.

If the lamps are in good order and the engine keeps a constant speed, the machines are probably so connected together by the bed plate, or opposing poles—*i.e.*, like poles—of the field magnets so closely, that the magnetic system is in a state of unstable equilibrium. If, then, the current in one machine increases, consequent upon an alteration in the resistance of the arc of the lamp it is driving, the field magnets of that machine are strengthened, and the field magnets of the other machine neutralised to a greater or less extent, and first one machine, then the other, will have the ascendancy.—Yours, &c., W. B. SAYERS.

Chelmsford, July 18, 1882.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I offer a suggestion as to the cause of the trouble that your correspondent "Wonderer" experiences with his dynamos.

I presume that, being small machines, they are both driven by one engine. Well, then, this being the case, any irregularity in the action of one of the lamps would cause an increase or decrease in the resistance of its machine, thus taking some of the load off the engine, or *vice versâ*, which would sensibly affect the speed of the engine, and, consequently, the current in the other dynamo and its lamp.

Why not connect the machines and lamps up in one circuit, and thus equalise both. I shall be glad to know if this succeeds.—Yours, &c., "ACCUMULATOR."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The effect your correspondent, "Wonderer," observes may be due to two causes. If he is driving both dynamos from one engine, should the feeding arrangement of either lamp stick or work sluggishly, or the arc increase so much as to materially reduce the strength of the current, and perhaps temporarily put that lamp out, then the engine being freed from a portion of its load, would, unless it was very carefully governed, increase its speed. The other lamp would thereby receive an increased strength of current, and would probably burn brighter until the other lamp got into working order again, or the engine was reduced to its normal speed.

As, also, his two dynamos are placed very close together, if their position is favourable, the sudden cessation of the current, or even a large decrease in the current strength in one dynamo, may *induce* a powerful current of momentary duration in the other.

Should "Wonderer's" lamps go out from the carbons running together and sticking, the sudden increase in the current strength in one dynamo may also give rise to a momentary induced current in the other.

The position of the dynamos themselves relatively to each other and to their external circuits, will determine whether these induced currents increase or decrease the working current passing through the machines and lamps.

In the case, however, where the carbons of one lamp stick together and become incandescent, we should expect that the additional pull upon the engine would tend to lessen its speed, and so deaden the light given out by the other lamp, in spite of the assistance of the induced currents.

If "Wonderer" has any further difficulties with his apparatus, and will place himself in communication with us, we shall be pleased to help him out with them.—Yours &c.,

SYDNEY F. WALKER AND OLLIVER.

Black Boy Yard, Long Row, Nottingham.

ELECTRIC LIGHTING AND GAS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with considerable interest Mr. Sugg's very able lecture in *The Electrician* of last week on the com-

Digitized by Google

parative merits of gas and the electric light, in which he says that gas is much more suitable for large spaces than arc lights, and more steady.

There is an old saying, "seeing is believing," and if Mr. Sugg will, any evening except Saturday, take a walk down Fleet-street, and place his back against the wall opposite the new *Daily Telegraph* offices, he will have an exceptional opportunity of comparing his latest three light patent burners burning within a few yards of a new arc lamp, which will, I think, very much modify his opinion.

The patent arc lamp in front of the new *Daily Telegraph* offices simply drowns his lights, and when I saw the sun lights inside of the offices mentioned put on while the arc lights, Fyfe and Main's, were alight, the electric lights were infinitely more steady than that of the gas.

For large consumers, light for light, electricity is far cheaper than that of gas, to say nothing of the advantages of a pure atmosphere and clean ceilings.—Yours, &c.,

A Believer in the Future of the Electric Light.

July 13, 1882.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I notice in your issue of Saturday last a contribution modestly described as "sufficiently long," which might be succinctly disposed of on the *qui s'excuse s'accuse* theory; but as from time to time gentlemen having a very little acquaintance with subjects rush into "print with delightful archness which arises from ignorance," it may be as well to recognise the gentleman's invitation, and recommend him to further pursue his studies, as in the immediate neighbourhood particularised the enterprising proprietors of the *Daily Telegraph* afford ample opportunity for competitive examination. He has in juxtaposition gas, vigorously aided by his excellent burners, struggling to make itself seen in the presence of an electric lamp on the public highway; while within the offices six sunlights of 216 (36 by 6) are paled into insignificance by two similar lamps to the one named. If "popular prejudice" does not reason it is open to conviction by ocular demonstration. Personal prejudice is quite another matter.

Surely it cannot be considered an argument that, because the House of Commons rejected a crude electric lamp in favour of gas, and because a provincial paper avers that an assembly listening to a "Grand Concert" could not discover where daylight ended and gaslight was introduced, that his case is made out, although he seems so self satisfied as to say, "Sufficient for me in this paper to feel that I have proved that gas is steadier and readier and more useful for the purpose of lighting large interior and exterior space than electricity."

When a comparison can be instituted between some of the modern electric lamps and gas with even the best of burners I shall beforehand make bold to say that the result of the Fleet-street demonstration will be considerably amplified.

To refer to the purity of the atmosphere in connection with electricity is mere begging the question. Safety can be disposed of by various theatre experiences, and the Paris catastrophe of yesterday. Facts speak volumes!

In the matter of cost, when the gas companies decree to give their illuminating power gratis, and rest content with the handsome profits on products, even then, after the first outlay is overcome, will electric lighting be recognised and generally adopted?

Instead of employing a dubious vulgarism, "There is nothing like leather," if the gentleman had frankly written "There is nothing like gas and Sugg's burners," he would have been appreciated for manly candour.—Yours, &c.,

July 12, 1882 A Believer in Electricity.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In my letter to you of the 26th June I endeavoured to keep Mr. Harbord to the point in dispute by asking him to produce certain information which, if he did not give, I would not answer another letter of his. He has again written to you without giving the desiderated information, therefore I would not have replied but for his having attempted to deprive me of the originality of my experiments with the Leyden jar, published in your columns. I call on Mr. Harbord to quote the passage of Sir William Watson's writings, and give the volume and page where they are to be found.

As to the question of electricity being or not being matter, I would as soon think of speaking to the moon as to correspond with Mr. Harbord about electricity being matter until the preliminary and fundamental question is settled—namely, Is that which some men have called "static electricity" divisable into two electricities, or, to use Mr. Harbord's words, Is the *force* decomposable and recomposable? Until this (the first step in the process) has been proved it would be madness to attempt to discuss with Mr. Harbord the question as to whether electricity is or is not matter. I have in your columns produced experimental proof that there is only one electricity. No man has been able to rebut the evidence I have given on this subject. On the other hand, Mr. Harbord has again and again written to the effect that electricity is divisible or can be "decomposed and recomposed." I challenge him to produce proof that that which some men call "static electricity" is divisible into two kinds, or is a force that is decomposable and recomposable. Until the foregoing fundamental point is forced home on Mr. Harbord's mind it is impossible for him to understand the question as to whether electricity is or is not matter.

In Mr. Harbord's last letter, p. 184, he asserts that I have "said" that "there is no such thing as magnetic repulsion." He places these words in quotation marks as if I had used them, and charges me with ignorance for having done so. I have neither said nor written that there is no such thing as "magnetic repulsion." It is a wrong statement of Mr. Harbord's, and shows the worthlessness of his writings in a scientific point of view; for true science is professedly a search to obtain truth.

Let me here note that the point I have endeavoured to keep Mr. Harbord to is exactly the point I endeavoured to bring Dr. Shettle to—namely, that he has founded his theory of electricity on the assumption that the so-called "static electricity" is divisible into two forces. Although Dr. Shettle were to write letters in *The Electrician* till the day of his death, as far as the nature of electricity is concerned all his writings will be valueless, because all his statements about the nature of electricity are founded on the false assumption of "static electricity" being of a compound nature, and of this he has given no proof. I have given proof that there is only one electricity, and Dr. Shettle has not attempted to show that my proof is wrong.—Yours, &c.,

James Johnstone.

Experiment Rooms, 1, James-square, Edinburgh,
July 10, 1882.

NOTATION AND NOMENCLATURE.

TO THE EDITOR OF THE ELECTRICIAN.

(Translation.)

Sir: In your leading article of the 19th inst. you rightly demand uniformity of notation and nomenclature, but as you have honoured me by quoting the English translation of my book permit me to make an observation on this subject.

The adoption of the letter I as indicative of the intensity of the current (what is called *current* in English) has the advantage of avoiding all confusion, such as you call attention to a few lines further down as existing "in a book used by students preparing for the London University examination," for the notation of the five electrical quantities can then be indicated as follows:—Intensity (current), I; electromotive force, E; resistance, R; quantity, Q; capacity, C.

As to the preference which you appear to give to foot-pounds in place of centimetre-grammes, it seems to me to be the less justified in that the electrical units almost uni-

Digitized by Google

versally adopted at the present time are based on the C.-G.-S. system.

The article of Mr. Samuel Phillips which you print immediately after your leading article only still more increases the confusion against which you are combating, since the practical units which the author extols so highly are a mixture of metrical, C.-G.-S., and English units, in a word, a mixture which is neither flesh nor fish, equally unqualified to satisfy *savants* and practical men, since these units are not based on any co-ordination, and are absolutely independent of one another.—Accept, &c., E. HOSPITALIER.

23, Rue D'Arcole, Paris, 16th July, 1882.

THE ELECTRIC LIGHTING BILL.

Below we give a report of the debate on this Bill, which took place in the House of Commons on Saturday last, as it appeared in *The Observer* of the 16th instant:—

On the order of the day for going into Committee upon this Bill,

Colonel MAKINS said that when the question of holding a Saturday sitting was discussed on Thursday night he intimated that he would not move the amendment of which he had given notice until the third reading, but he had since consulted with the President of the Board of Trade, who thought it would be better to take the discussion to-day. Although it was well known that he was connected with gas companies, he did not appear there as the representative of those interests as opposed to the present measure. On the contrary, the gas companies, as far as he was able to gather, were satisfied with the general scope of the measure, and, indeed, regarded it as a very strong and a very essential effort on behalf of the Board of Trade to grapple with a very difficult question. But, although the gas companies were not in any way opposed to the Bill in its general details, yet there were one or two matters of principle which, apart from that interest, he deemed it desirable to call the attention of the House to. In the first place, in regard to the question of electric lighting, it was not the case that any Bill the House could pass would have any effect upon the competition which naturally must arise between various systems of lighting. The results of that competition must, in the end, depend on efficiency and economy; and, although regulations might be valuable in the interests of the public, he did not see how in any way they could affect the interests of the gas companies, who could well afford to look on as to what was going on in the world in reference to electric lighting. They had had forty years' start, and in the course of that period an enormous amount of capital had been provided under the sanction of Parliament, and expended in gas lighting in every part of the kingdom. During the last few years electric lighting, a novel mode of illumination, had made great progress. That progress he ventured to think had been more scientific than practical, but no doubt it had made even practical advance, and the exhibitions at Paris and the Crystal Palace had demonstrated its valuable qualities. Within the last few weeks fifty-five companies had been registered, dealing with the question of electric lighting, and the aggregate capital approached, or even exceeded, the £13,000,000 or £14,000,000 expended during the last forty years in gas lighting. Although he should be the last person in the world to grudge the scientific men who had been engaged an adequate reward for their labours, he thought at the same time that it would be patent to the House that a considerable portion of this capital was not likely to prove remunerative except to the individuals to whom he had referred. Two points which he desired to put before the House were, first, the power taken by the Board of Trade to grant licenses to corporations and companies; and, secondly, the fact that the local authorities were to be entrusted with the powers contained in the Bill, and might plunge into large expenditure for purely experimental and speculative purposes, without being under the necessity of obtaining the assent of the ratepayers. As to the first point, the power asked for by the Board of Trade had hitherto been exercised by Parliament in the shape of provisional orders, and it was an entirely new departure for one of the departments of the State to usurp to itself the powers of the Legislature in matters of this kind. There was also, in his opinion, something quite new in the definition given by this Bill to the term "public lighting," for it had been made to include not only the lighting of streets and thoroughfares, but also vestry halls, churches, and theatres. Beyond this, power was taken to supply the electric light to private consumers, without, as had hitherto been the usage, previous acquisition of the existing sources of supply. As to the power to local authorities to use the money of the ratepayers in the supply of electric lighting without obtaining their consent, he strongly objected to what would be the means of creating within such bodies a sort of bureaucracy which would have an almost unlimited authority over the public purse. He therefore moved "That it is undesirable to retain in the Bill the novel powers proposed to be given to the Board of Trade to grant licenses to local authorities or persons enabling them to exercise power hitherto only granted by Act of Parliament or provisional order confirmed by Act of Parliament; and the power given to local authorities under Clauses 5 and 6 and other parts of the Bill to raise money on the credit of local rates without the consent of the ratepayers, for the purpose of competing with private capital, are contrary to every principle hitherto recognised by the Legislature, and that no Bill containing such powers will be acceptable to this House."

Mr. CARBUTT was glad the hon. and gallant gentleman had opposed what he (Mr. Carbutt) regarded as quite a new departure in legislation, the principle of which, if carried out, would probably hereafter be applied to railway property, and entail by the arbitrary mode of purchase now proposed enormous loss on the present shareholders. The Bill was a violation of all the principles of political economy, and if the purchase clause was carried out, would be a violation of the principle of fair dealing. The proposition was that the public would like a new mode of lighting developed if it could be developed; but the public were not sure, and public bodies would probably not risk the ratepayers' money in experiments. They therefore said, let this be done by private persons, and if they failed there would be no obligation on public bodies to buy, but if they succeeded the public bodies should be entitled to buy at the value of old material. Moreover, the option to buy was not to be given once for all, but was to be recurrent, so that the moment the undertakers who took the first risk began to make a profit they would be despoiled. He protested against the adoption of such a principle in legislation upon these matters.

Mr. SLAGG contended that as electric science was at the present time in a purely experimental condition, it was not possible to fix the value of the undertakings that might be purchased under the Bill, and he asked why outside companies should be encouraged to come in and make enormous profits out of public communities without some power being given to the local authorities such as was provided by this Bill.

Mr. W. FOWLER protested against the proposal in the Bill to give corporations the right to buy up an electric lighting company after fifteen years, seeing they had given tramway companies under the Tramways Act twenty-one years. They ought to give electric lighting companies at least as long as they had given tramway companies. They seemed to be going from one extreme to the other. They gave gas companies too much, and now they were giving electric companies too little. He quite admitted that people were wild about electric lighting, but what they advanced their money for was not for the transaction of regular business, but for speculation, in the hopes of selling their shares at some gigantic profit. He noticed the other day that the £4 paid shares of the Brush Company were worth £28. This was a very demoralising price [laughter]. He was afraid if they did not take care they would discourage people from laying out their money. They held out the prospect to them of heads I win, tails you lose, as the corporations could not lose [laughter]. His strong conviction was that Parliament was going too far in the way of protecting local corporations and discouraging private enterprise.

Mr. STANHOPE thought the discussion on the points which had been raised would be much more advatageous if conducted in committee.

Mr. CHAMBERLAIN regarded the matters that had been raised by the hon. member for South Essex (Colonel Makins) as of considerable importance. If his amendment were carried it would strike one of the principal clauses of the Bill, and might be considered almost as fatal. The questions which had been raised by the members for Manchester and Cambridge were really questions of detail as to the precise nature of the purchase clauses inserted in the Bill, which would be much more conveniently discussed in committee. This question had been fully considered by a committee upstairs. All these powerful interests were represented by counsel, a great number of meetings were held, everything that could be said on the subject was carefully listened to, and, he was glad to say, that upon all the important matters which they had to decide, the committee was practically unanimous. He quite admitted that the proposal of the Bill to grant a license was a novel power, but it followed out the recommendation which was made by a very strong committee which sat on the subject in 1870, of which the present chairman of committees was chairman. Electricity was entirely in an experimental state at present, and the object of the Government in introducing this Bill and the object of the committee he was sure

Digitized by Google

had been to give every facility for experimental processess in connection with electricity. If they proceeded by way of provisional order, with the probability that such provisional orders might in every case be opposed by the great vested interests which existed, and which were, to a certain extent, hostile to the new illuminant, they would put inventors and others, consumers desirous of having this light introduced, at such a great disadvantage in consequence of the enormous cost of obtaining powers that they would materially interfere with the progress of this new science; and, therefore, it was thought desirable to introduce some new method by which the experimental stage might be conducted with less expense. The proposal was this—that where a local authority which happened to represent fully the wishes of the district was aggrieved in the application, then the Board of Trade, after hearing all parties who desired to make any objection or representation on this subject, might grant a license, of course for the experiment for the limited period of five years, and he certainly thought that that would be an extremely convenient proceeding, and one that he hoped the House would be willing to adopt. As to the new distinction which the hon. member said had been created between lighting for public and private purposes, that was not really a question of any importance. The greater covered the less in this matter. The second part of the hon. member's resolution went on to protest against what he called the new power to borrow or raise money on rates in competition with private capital, and without the consent of the ratepayers. That raised two important and separate questions. The first was whether such raising of public money was justifiable in competition with private capital.

Colonel MAKINS: Raised under an Act of Parliament.

Mr. CHAMBERLAIN: Under an Act of Parliament or otherwise; but the second point was whether such power should be granted without the consent of the ratepayers. The first question, it seemed to him, was raised in the interests of gas companies and others who fancied they had got a vested interest in lighting, and desired to prevent any competition; and the second question was raised in the supposed interest of the ratepayers. In regard to the first question, it was a mistake to assert that Parliament had only given power to public authorities to raise and expend money in competition with private capital. There were the cases of tramways, baths, and washhouses, and gas itself, most of the corporations having power not merely to supply gas, which itself comes into competition with other forms of illumination, such as paraffin oil, but also in the majority of cases to supply fittings to houses in competition with private undertakings. This competition proceeded on the assumption—which he ventured to think was entirely without foundation—that gas companies, or other companies having at the present time authority to supply gas, had obtained from Parliament authority to supply light. In his opinion, gas companies or corporations having powers to supply gas had obtained no right whatever to be protected by Parliament against the introduction of any new illuminant. If that was the case, it appeared to him to be incorrect to speak of the new illuminant as coming into competition with private capital, and the House would be perfectly justified in giving the powers sought for to local authorities. Then there came the second question, whether these local authorities should exercise these powers without what the hon. member called the consent of the ratepayers; and he appealed to the Borough Funds Act, under which corporations were at the present time compelled, if they desired that their expenses should be borne by the rates, to appeal to the ratepayers before applying for any new Act of Parliament, or opposing an Act of Parliament applied for by any one else. He altogether denied the statement of the hon. member that it worked well. In the opinion of those who he (Mr. Chamberlain) thought were best qualified to judge, on the contrary, there was no provision in the Municipal Acts which was more resented, and, in his opinion, more properly resented by corporations than this. If the corporations were really representative of the interests of the ratepayers, then he said they were bound to trust them wholly, and it was an unconstitutional proceeding to submit all their opinions and decisions to a meeting of ratepayers. The effect of this was bad in more ways than one. It undoubtedly did lessen the efficiency and authority of corporations, but it also tended to degrade them in their own eyes, and to lessen their responsibility and their usefulness, and he hoped to see the time when this Act will be repealed, or, at all events, amended. Although this Bill did not give an appeal to the ratepayers, yet it provided before any license or provisional order was granted that all persons interested should be heard by the Board of Trade. The objections of ratepayers, therefore, would undoubtedly be attended to as they were now in the provisional orders applied for and granted by the Local Government Board for a great number of purposes. This system had given universal satisfaction. It had worked admirably, saved the time of Parliament, and saved the money of the ratepayers. It was that system and no more that this Bill proposed to somewhat further develop. The amendment of the hon. member for South Essex would have a distinct tendency to prevent the general adoption of electric lighting. With these observations he left the matter in the hands of the House.

Mr. WARTON thought that in this Bill the interests of one class had been overlooked—he referred to the inventors—and he believed that their efforts would be hampered by the proposals advocated by the President of the Board of Trade. Their patents were their license, and they wanted none from the Board of Trade. He strongly urged that the interests of this class ought to be respected. Without offence to the right hon. gentleman, he might be permitted to say that the Board of Trade did not content itself with its own business, but showed the tendency to encroach on the duties of other departments. It had taken away from the Trinity House the management of lighthouses, and, if he might use the expression, it had stolen from the Admiralty certain duties connected with foreshore. No doubt this was all very natural, and that was the reason why they had been called down to the House on a Saturday to discuss a Bill which might, under different circumstances, have taken its chance with others in the ordinary way. His feeling with regard to the Board of Trade as a body was that it possessed no scientific claims whatever, and he regarded the adoption of the bureaucratic, or French principle of leaving everything to the department and its highly intelligent President as unsatisfactory, if not unconstitutional. Not only did he advocate freedom for inventors, but he urged freedom for the electric companies to make their own way in the world as other companies had hitherto done, untrammelled by the Board of Trade and unfettered by having to apply for licenses, and being obliged to stand or fall on their own merits. There was another point—the interests of the ratepayers—and he regarded the continual attempts to press more and more heavily upon them as really abominable. Let them burn tallow candles, gas, or the costly electric light as they pleased, but do not, he said, compel them to do either of the three.

Mr. MACIVER considered that the objections to the Bill were rather increased than decreased by the speech of the President of the Board of Trade, who had dealt with the matter as if there were only two interests involved. He seemed altogether to overlook such cases, and they were numerous, as that of the Corporation of Birkenhead, who were the owners of the gasworks. There was no feeling of antagonism towards the electric light, but that was hardly a reason why its promoters should have advantages which those who at an earlier time embarked in the gas project did not possess. All that was wanted was absolute fair play, and he contended that those who were connected with electric lighting should be put on the same footing in the matter of competition as the other companies. He concurred in what the hon. member who had just spoken had said with respect to the Board of Trade. It was a department of which he had had very long experience from various points of view, and while he had always—and with reason—regarded certain of its members with respect, he looked upon it as a department which, in more than one particular, was thoroughly incompetent. The Speaker, he hoped, would pardon him for saying this, because not only he, but also the Archbishop of Canterbury, was a member of the Board [laughter], but he supposed that neither of them took any active part in its duties. If they did, no doubt his objections would be entirely removed [laughter], and the work imposed by the Bill would be in good hands. But no one knew to whom these powers would be entrusted, and he considered it wrong that the Board should possess them. He looked upon the illustration taken by the right hon. gentleman from the case of the tramways as most unfortunate and incomplete.

Colonel MAKINS said that, after the discussion which had taken place, he did not intend to press his amendment.

The amendment was then by leave withdrawn, and the House went into Committee on the Bill.

Clause 1 (short title) was agreed to.

On Clause 2, which deals with the granting of licenses, authorising the supply of electricity,

Mr. CORBETT called attention to Sub-Section 2, which set forth that a license should be for any period not exceeding five years, but might, at the expiration of such license, be renewed at any time with the consent of the local authority, upon such terms and conditions as the Board of Works might determine. He moved to leave out the word "five" and insert "seven."

Mr. CHAMBERLAIN said that the only case in which the license could not be renewed was in the case of the local authority refusing its consent. If the hon. gentleman proposed that the Board of Trade should go outside the consent of the local authority, they would be usurping the authority of Parliament in a way they had never hitherto attempted to usurp it. It was one thing to say that the Board of Trade should be empowered to grant a license with the consent of the local authority, but it was

Digitized by Google

another and very different thing to say that it should act without that consent.

Mr. MACIVER wished to know who were the Board of Trade for the purposes of this Act?

Mr. CHAMBERLAIN replied that it was quite true that, technically, the constitution included the Archbishop of Canterbury, the Prime Minister, Mr. Speaker, and many other personages, but the board for many years had never met.

Sir J. LUBBOCK pointed out that a company might say to a local authority that, "We will not go to the expense of laying down wires and procuring plant for the short space of five years, but we will make the experiment if you will guarantee us an existence of ten years." Would it be in the power of the local authority to give such a guarantee?

Mr. CHAMBERLAIN said there was nothing in the Bill to prevent a local authority from agreeing with a company that at the expiration of five years their consent should continue. A question had been asked on this point on a previous occasion, and there had been some discussion on the point.

Mr. W. FOWLER said that at the end of the first five years there might be a new corporation, and a bargain made by their predecessors would not be binding on the new body.

Mr. CHAMBERLAIN said that corporations were continually binding their successors.

Sir G. CAMPBELL said it appeared to him to be a most alarming doctrine. One corporation might be in office for five years and it might be followed by another of totally different views on local politics, and yet they were to be bound to accept the policy of their predecessors.

Mr. CHAMBERLAIN said the successors of a corporation would not be bound as to policy, but only in the carrying out of a contract. The consent of the Board of Trade to the renewal of a license would still be required.

Mr. W. FOWLER said a corporation could not bind its successors beyond the spirit of the Act.

Mr. Serjeant SIMON said that a corporation was a perpetual body, and could enter into an agreement in perpetuity for any term of years. There could be no doubt in the mind of any lawyer on this point.

Mr. SHAW thought it would be well for the inquiries of the Board of Trade to be made locally. He considered the period mentioned in the Bill—viz., five years—would be a very short one, and capitalists would be loth to embark their money in enterprises which might be of such short duration.

Mr. CHAMBERLAIN said the points raised by the hon. member were of great importance, and he (Mr. Chamberlain) was in sympathy with the hon. member. It would be desirable that in many cases local inquiries should be held; and, although these were not provided for in the Bill, they would be provided for in the regulations framed by the Board of Trade. As to the period over which the electrical experiments might extend, they could be conducted by provisional order as well as by license; and, in that case, Parliament would be able to authorise the continuance of a scheme.

After some further conversation the amendment was withdrawn.

Mr. WARTON moved to amend the sub-section by providing that the license could be renewed at the expiration of the period of five years, "or at any time after" that expiration.

Mr. CHAMBERLAIN promised to consider the point, and, if there was a defect in the Bill, to amend it on report.

The amendment was accordingly withdrawn.

Mr. WARTON then proposed words to make the renewal "for a like period" to that of the original license.

The ATTORNEY-GENERAL said the period was governed by words in the earlier part of the sub-section.

Colonel MAKINS wished to know how many renewals could take place before it became necessary to apply for a provisional order? It was very important that the committee should come to a decision in these matters, and it was quite evident that before five years were over the company supplying the light must give satisfaction to the local authorities, or else the whole thing would lapse. He moved the omission of the words "at any time," which would compel the parties to come to some arrangement with the local authorities.

Mr. CHAMBERLAIN pointed out that the effect of omitting these words would be to provide for only one renewal of the license and no more. He thought there should be a continuing power to grant renewals so long as the conditions existed. However, he quite understood the object to attain which the amendment was moved, and he promised to consult the draughtsman, and if it were found necessary for the sake of greater clearness to make any alteration in the language of the clause he would bring it up at a later stage.

After some further discussion, the amendment was withdrawn.

Mr. CALLAN moved an amendment providing that the notices given to the public should state fully the terms on which it was proposed that the electric light should be supplied, in order that all who were interested should know what those terms were.

Mr. CHAMBERLAIN explained that the object in view was attained as well as it could be by Clause 3. It would be difficult to insert the terms in the application, for they could only be arrived at after full consideration between the parties.

The amendment was withdrawn.

Mr. MACIVER moved an amendment, to substitute for "the Board of Trade" the words "the President of the Board of Trade" as the controlling authority. They all knew in that House that for all practical purposes the President was the Board of Trade, but that fact was not so well known by the public outside.

Mr. CHAMBERLAIN could hardly believe that the hon. gentleman was serious in proposing to make a great constitutional change in an amendment to an electric lighting bill. The adoption of the amendment would raise all sorts of difficulties.

On the question that Clause 2 stand part of the Bill,

Colonel MAKINS made a final protest against the measure, on the ground that it set a bad precedent and introduced a new principle, under which great public works were to be sanctioned or legislated for not by Parliament but by the Board of Trade. It might hereafter come to happen that local authorities would obtain licenses from the Board of Trade for the construction of docks or railways, or the carrying out of almost any sort of enterprise.

Mr. FRITH suggested that the publication of notices, &c., might give sufficient publicity to provincial schemes, but it would never inform the ratepayers of the metropolis in regard to London schemes. He hoped the Government would consider whether different provisions could not be made for London in regard to this matter.

The clause was then agreed to, as were Clauses 3 and 4. On Clause 5,

Mr. BOLTON moved an amendment, the object of which was to make it perfectly clear that only those who availed themselves of the option given under the Bill to use the electric light should be rendered liable to pay for it. It was evident that, as the clause stood at present, the local authority might enter into a speculation to provide an electric light for any locality, and charge a very low price for the use of it, and then avail themselves of this clause, by which others, who were not using the light at all, were assessed for the cost.

Mr. CHAMBERLAIN said that some sort of confidence must be reposed in the common justice and honesty of the local authorities. If those authorities were to act in the manner suggested by Mr. Bolton, they could not possibly remain in office.

The amendment was negatived.

Mr. PUGH moved an amendment providing that no local authority should be empowered to enter upon a scheme for electric lighting unless it had previously obtained the definite sanction of the ratepayers. He pointed out that the Borough Funds Act provided that no corporation or other local authority should embark upon any expensive scheme unless the ratepayers had been consulted in the matter. He cared little whether the sanction was given by a meeting of the ratepayers or by some local inquiry, but that such sanction was necessary he believed all hon. gentlemen would admit.

Colonel MAKINS was glad the hon. member had proposed this amendment, though he was not sure that by proposing to embody a section of the Borough Funds Act he had adopted the wisest course to secure the end in view. He observed that in a later portion of the Bill it was provided that an inquiry "may" be held into the merits of an electric lighting scheme. If the President of the Board of Trade would consent to make the inquiry compulsory, there would be no need for the present amendment.

Mr. CHAMBERLAIN did not think the amendment would attain the object for the hon. gentleman, for its effect would be that a local authority would have to obtain the consent of the ratepayers whenever they wished to incur fresh expense in connection with the undertaking. Such shackles were surely not necessary in the case of greater corporations, but he agreed that, in the case of local authorities in country districts, there was not that security which public opinion gave in large towns, and, therefore, something of the kind suggested was necessary. He must point out that under the existing law there was every security against an absolute abuse of power entrusted by ratepayers to their representatives.

The amendment was withdrawn.

Mr. NICHOLSON proposed that the licenses should be granted for twenty-one years instead of fifteen years. He believed that such an alteration would tend to the greater security of the capital invested.

Mr. CHAMBERLAIN said the term fixed in the Bill was the result of a compromise. Between the term of seven years originally appearing in the Bill and the term of twenty-one

Digitized by Google

years which the counsel for the eletric companies argued in support of, the Committee took the middle course, believing that fifteen years gave sufficient time for the development of what really was an experiment, while to give a longer lease of monopoly might prejudice the interest of the public in favour of those of private speculators. The electric light companies all of them, with the exception of the Edison Light Company, had expressed themselves as satisfied with the term of fifteen years. In the company he had mentioned he believed his hon. friend was interested, but all the other companies had declared that the time (fifteen years) was quite sufficient to justify them in the experiments they desired to make.

Mr. CALLAN expressed his surprise that a member of the committee should be alluded to as interested in one particular company concerned in the result of the discussion. In private committees it was usual for every member to sign a declaration to the effect that he was not personally interested in the matter under investigation. He was sorry that a Minister should by his words give an implied sanction to the interference of a member in the proceedings of a committee in which he was personally interested [oh].

Mr. MORGAN LLOYD as a matter of order asked the chairman where they were [laughter]?

The CHAIRMAN having, in reply to this question and another put by Mr. Carbutt, explained that the point was simply whether the time within which the purchase should be effected should be fifteen or twenty-one years.

Colonel MAKINS explained that what Mr. Callan had said referred only to private Bills, not Bills of a public character.

Mr. M. HENRY also pointed out the same distinction.

Mr. CARBUTT supported the proposition for making the period fifteen years.

Mr. STOREY-MASKELYNE took the opposite view,

And the amendment was withdrawn.

Mr. NICHOLSON moved an amendment to provide that the purchase should be agreed upon with an undertaking for an addition for goodwill and compensation for severance.

This was opposed by Mr. RATHBONE, and supported by Sir J. LUBBOCK.

Mr. CHAMBERLAIN said: Of course, in the case of gas companies' plant being purchased, allowance would have to be made for the depreciation of plant by working, as was done in every other manufacturing trade. It must be remembered that though there was no purchase clause inserted in the Gas Acts, there was a clause limiting the dividends, and there was nothing of the kind in the present Bill.

Mr. CROSS would like it to be understood that nothing like the same exorbitant dividend would, or could, be paid by any electric lighting company as had been paid by the gas companies.

Mr. MORGAN LLOYD advised the insertion of a clause fixing the value of a going concern.

On Clause 20,

Mr. ION TRANT HAMILTON moved to insert after the word "modifications," "this Act shall be read and take effect, so far as Ireland is concerned, as if the Local Government Board for Ireland was in all instances substituted for the Board of Trade."

Mr. CHAMBERLAIN said the object of the Board of Trade was to consult the wishes of the Irish members so as to make the Bill as practicable as possible. The same provisions as applied to England and Scotland would be applied to Ireland and he respectfully asked his hon. friend to allow the amendment to be dropped.

Mr. STANHOPE thought it would be desirable to leave it in the ands of the Board of Trade.

Alderman BARRON moved the following amendment:—"No application for a provisional order on the part of any company or person shall be made in respect of all or any part of the district of a municipal or other local authority without six months' notice in writing (which shall define the area intended to be comprised therein) to such authority, who shall, within that period be entitled to make application for a provisional order in respect of all or any part (including the area defined in such notice) of such district; and, until such application has been disposed of, no other application shall be entertained."

Mr. RAMSAY moved to report progress, on the ground that the time allotted to the Bill by the President of the Board of Trade was past, and Scotch business was waiting that had been mentioned in the Queen's Speech three times; whereas this Bill had not been mentioned at all.

Mr. Serjeant SIMON hoped the motion to report progress would not be persisted in.

Sir G. CAMPBELL urged the House to go on with the Scotch Bill, even up to midnight.

Mr. STANHOPE asked for an assurance that the third order on the paper, the Annuities and Insurance Bill, would not be taken, protesting against English members being kept waiting several hours for that measure, while the Scotch Bill was being discussed.

Mr. RAMSAY explained that he made his motion because it was not right for the Government to have placed the Scotch Bill second on the paper. He would, however, withdraw his motion.

The motion having been withdrawn, some further discussion took place upon the amendment of the hon. member for Leeds, and eventually the committee divided, and rejected the amendment by 88 to 29.

The schedule of the Bill was agreed to, and the Bill passed through committee as amended.

THE SOUTH AFRICAN "BRUSH" ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of this Company was held at the Cannon-street Station Hotel, on the 17th inst., followed by the first ordinary general meeting, "for the purpose of transacting the ordinary business of the Company."

Lieut.-Colonel GEORGE COXON presided.

The SECRETARY (Mr. Thomas J. Seel) having read the notice convening the meetings,

The CHAIRMAN said: You are aware that this (referring to the extraordinary) meeting is called for the purpose of confirming the proceedings of the meeting, held recently in this hall, to rescind certain parts of the Articles of the Association. You are all in possession of the alterations proposed in the article, and I move the confirmation of the resolution.

Mr. ATKINSON having seconded the motion, it was carried unanimously.

The CHAIRMAN then said: I have now the honour to open the first general meeting of the Company. On the last occasion when we met there were certain queries put to us, I think, rather prematurely, considering that the Company had only just started, and I intimated that on this occasion we would be more prepared and ready to give any information with regard to the progress and operations and the prospects of the Company than we were then prepared to do. In pursuance of that engagement, I will, with your permission, read to you a few notes I have made on the subject of our proceedings, our wish being, of course, as representatives of the shareholders of this Company, and as custodians of their interests, to hold everything in common with them, and to retain nothing that should be made public. Of course there are certain matters, with regard to the terms of contracts particularly, that you will understand, as men of business, it would be absurd for us to make public - that is, I mean, to publish them to the whole world —no more than any one of you who are in business would think it wise to publish the terms of your contracts, or your business, to the world; but there is no shareholder to whom all the books and papers, and everything, even contracts, is not at all times open, and our secretary will always be prepared to give any information to any shareholder who may wish to have it. With regard to that there is no restriction. The Company was registered on the 13th of May last, and it will be no doubt satisfactory to the shareholders if I say a few words with reference to the position and prospects of the Company. The shareholders will remember that in 1881 Mr. Blain and Mr. Macdonald acquired from the Anglo-American Brush Electric Light Corporation (Limited) a license to use in South Africa the Brush system of electric lighting, and had sent to the Cape Mr. Donald Macdonald, who is now colonial manager of the Company; and they also purchased and forwarded to South Africa steam engines, dynamo machines, and plant, the Company acquiring from them not only the concession for the use of the Brush system, but all the plant in the colony and in transit, and the benefit of the contracts in negotiation which had been arranged, or were in course of being arranged. The shareholders will be aware that a company starting a new business, such as ours, will necessarily have to expend money in experiments, and in temporary installations, but the negotiations which had made most progress at the time of the incorporation of the Company related to the lighting of Kimberley with the electric light. So long ago as October last the manager reported that since his arrival at Kimberley he had had several conferences with the Town Council on the subject of lighting the town, and from what had transpired he believed there was every prospect of securing a good contract. From time to time he reported the progress which was made in the negotiations for the contract, and in January last he reported that he trusted soon to be able to state that the contract had been secured. I give you merely extracts of the letters bearing on this point, but I retain nothing which you should be made acquainted with. In February he reported that the experimental lights had been started at Kimberley, and that he was pushing on the final arrangements with the Council. On the 2nd of March he reported that the light had been going steadily, and had given general satisfaction, and he went on to say that he was negotiating for the permanent installation, and that the difficulty which stood in the way of making the contract was that it was understood that the lighting rate was not to exceed a penny in the pound, which was not sufficient to produce enough to provide sufficient remuneration for installing and working the thirty-two lamps required to light the town. And this is an important fact, that at that meeting an additional £3,000 was added to the rates generally, for the purpose of increasing the funds in hand for a lighting rate, in other words, £3,000 was added by the Corporation with the view of lighting the town with the electric lamp. He added that the whole question might again have to be submitted to a meeting of the ratepayers. Later on in the month Mr. Macdonald was informed that a meeting of ratepayers would immediately be called, and he thought his final proposal would be accepted, as a majority of the Council would support it, and the public had already declared in its favour. The terms of the proposal alluded to had previously been communicated by him to his principals here, and on the 11th of May (two days before the Company was registered) a telegram was received here, which ran as follows: —"Have made a contract for Kimberley." It was, therefore, gratifying to the directors to be able to announce, as they did in the prospectus, that a telegram had been received that a contract had been concluded with the

Digitized by Google

Mayor and Town Council of Kimberley to light that town with the Brush electric light on terms which the directors believed would prove highly remunerative to the Company. Our manager has since communicated to the directors the heads of the proposed contract, as agreed to by the Town Council. The directors do not consider that it would be advisable, in the interests of the Company, to make public the terms of this contract, but they are such as they consider satisfactory in all respects; and negotiations are still going forward with every prospect of final success. With reference to the Kimberley contract, the directors have to add that, although the contract was approved, and a resolution to seal it passed by the Town Council, a minority of the ratepapers (the majority have voted in its favour), interested from other motives, are still endeavouring to prevent its being carried into effect, and have gone so far as to commence proceedings to restrain the Town Council on the ground that the Corporation, as at present constituted, is not a legal body, because the voters' list for the present year has not been published. With reference to this hitch, our manager, on the 17th June, reports as follows:—"I am in no way anxious as to the result, but some further delay will be involved, as in nearly all important cases appeal is made from the High Court of Griqualand West to the Supreme Court of Cape Town." New plant is on the way, and the work is being proceeded with in order to complete the contract, and the directors cannot but think that public feeling in Kimberley will be too strong for the opposition, and that matters will go forward shortly with more smoothness than at present. The additional plant necessary for the completion of this contract, having been telegraphed for, is now on the way out. Concurrently with these negotiations, our manager, whose zeal, untiring energy, and great ability we hope one day to point to as a chief factor in the success of the Company, had been negotiating for the lighting of the Cape Town docks, harbour, and railway station, and has, we are happy to be able to report, brought them to a successful issue [applause]. On May 2nd he writes, with reference to the experimental installation in the Cape Town Docks: "The lamps have worked perfectly since writing to you on the 26th ult., and without interruption." He added that it was probable he would be asked to submit an estimate for lighting the outskirts of the town, where the gas company, whose contract has been continued for another year, have refused to lay their mains owing to the small number of lights required. On May 30th he writes: "The lights in the dock are giving every satisfaction, and I have reason to believe they will be permanently established." On the 23rd May he writes: "The lights are working well in dock for thirteen hours per night, but the Board have not yet come to any decision. The engineer informs me that the only hesitation on the part of the commissiones is the want of a perfect assurance that the Brush system is the best. He has been able to satisfy them that it is the cheapest (this is the Government engineer, not ours, who has satisfied them it is the cheapest light), and I think there is little doubt that it will be adopted." He adds, "The new company should, I think, work up incandescent lighting for houses, which would open a larger field than mere street lighting in all the interior towns where gas is beyond reach." On June 9 he writes:—"If the Kimberley Mining Board do not undertake the lighting of the mine, the companies will certainly light their own works, and it is from this source that I anticipate our chief business at the fields, but, owing to the extreme depression now prevailing, it may take some time to develop this branch of our business." On June 16 he writes:—"You will see from a copy of the *Port Elizabeth Herald*, which I forward, that permission has been obtained from the Town Council of that town to exhibit a set of lamps in the streets." Not very long ago I think the Town Council of Port Elizabeth refused to say anything to us about the light. In the same letter he states that he has addressed letters to the Government and Table Bay Harbour Board to the effect that it is the intention of this Company to establish in Cape Town a general electrical business, and that we shall be prepared to enter into contracts for supplying lights as fixed rates per light, per annum, to be worked by our own staff, and at our own risk. On the 4th of this month we received the following satisfactory telegram from our own manager:—"Cape Town, Dock railway agreed; sail to-day." That pointed to the satisfactory conclusion of the contract as to the dock and railway. "Sail to-day" means this:—As soon as the Company was formed we found that there were a great many things that could be better discussed if our manager were present, for he so thoroughly knows everything in connection with our field of operations in the Cape. We thought if he were present here we should be able to see a little better before us. With reference to the extract from the letter of May 23 on the subject of domestic lighting, prior to the formation of this company, Mr. Alexander Macdonald, of Messrs. Blain, Macdonald, and Co., had been granted the refusal of the patents for South Africa, held by the Electrical Storage and Force Company (Sellon and Volckmar accumulator) on exceptionally favourable terms. I may add that we may now call that the Sellon, Volckmar, and Faure accumulator, because that company has absorbed the patents of Mr. Faure as well as the well-known patents of Messrs. Sellon and Volckmar. In fact, they cover now all the patents that are applicable to what we may look upon as the groundwork of electrical patents—this accumulator. Mr. Macdonald, our agent, alludes to the question of lighting solely, but I need not tell you that the facilities for lighting given by this valuable accumulator are only really a small part of the immense power and advantage we shall possess by holding this patent in the matter of tramways and force for machinery—in fact, force as well as light. On the formation of this Company the directors were enabled, through the good offices of Mr. Macdonald, to open negotiations with the Electrical Storage Company, which have resulted in their acquiring these patents on the same favourable terms. The terms are exceptionally favourable, and we are very pleased to be able to tell you that we are now—so far as that goes, being the holders of the exclusive rights of the Brush system and the Sellon Accumulator system for the Cape of Good Hope—masters of the situation. There is only one matter which calls for our attention, which is the confirmation of the appointment of Messrs. Deloitte, Dever, and Co., as auditors of the Company. I beg to propose that.

Mr. P. A. Lloyd, a shareholder, seconded the motion, which was carried unanimously.

Mr. E. Hornsby moved a vote of thanks to the chairman, which was seconded.

A Shareholder inquired whether it was the intention of the Company to apply for a Stock Exchange quotation.

The motion having been carried,

The Chairman stated that they had applied for a quotation, but they could not possibly get it until the clause in their Articles of Association, the alteration of which they had confirmed that day, was made. They were now in the hands of the Stock Exchange committee. He thanked them for the vote of thanks.

The meeting then separated.

THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION (LIMITED).

An extraordinary general meeting of the Anglo-American Brush Electric Light Corporation (Limited) was held at the Cannon-street Hotel on the 18th inst. Sir Henry Tyler, M.P., presided.

The Secretary having read the notice convening the meeting,

The Chairman said: We have asked you to be good enough to meet us here to-day in order to get us out of a little difficulty. The difficulty is rather a serious one, and so far as I am aware an unprecedented one; but the fact is that we have a good deal of money now that we wish to distribute among you, and we are, unfortunately, precluded by our Articles of Association from distributing it. Now, these Articles of Association are our law, we are entirely bound by them, and it is only on our personal responsibility that we can depart from them. The amount that we wish to distribute among you we have arrived at this morning, after looking through all the figures of the Company, so far as we are able to make them up to the present. The 91st of our Articles of Association says: "A statement of the true financial position of the corporation, and a general balance-sheet made up to and, as on the preceding 31st day of December, so far as the business of the corporation abroad will allow, shall be laid before each ordinary general meeting after the first general meeting." You, therefore, see that we only make up our accounts and have an ordinary general meeting once a year. Now, we have not thought it at all worth while on this occasion to go through the process of taking stock and doing all that we should do in making up our accounts as at the end of every year. We have, however, prepared a rough balance-sheet to satisfy ourselves as to the amount we should distribute if you are good enough to give us permission to do so, and in that way we have arrived at the sum of £245,000, which we have to pay you whenever you like to receive it, and we propose with your permission that it should be paid about the middle of August. To do that we must alter Article 85 of the Articles of Association, which says, "The directors may, of their own authority, once in every year pay to the members a sum on account of dividends not exceeding the rate of 10 per cent. per annum on their respective shares." It is quite clear that the legal gentlemen who drew the articles, as well as the directors who sit before you, had no idea when this Company was incorporated of the success it was likely to meet with, and therefore we were precluded by them, and we precluded ourselves from paying more by way of interim dividend than 10 per cent. per annum. Now, having as you see, some £245,000 to distribute among you (and that I may say is entirely out of the profits of this undertaking)—having that amount to distribute among you, we are obliged to ask you to allow us to alter this article of association, and we have done so merely repeating what is stated in the previous article. "That the entire net profits of the corporation shall belong to the holders of the shares of the corporation (I think you will admit that that is a sound doctrine), and shall be divided among all the shareholders in the capital of the corporation for the time being, issued and fully paid up, or deemed and taken as fully paid up, and on such (if any) shares not being fully paid up, then only in respect of such shares in proportion to the amount of all calls then paid on such shares." You see that in the resolution we put before you to-day, and in the new article we to-day propose to you we have carried out precisely what is prescribed in the 84th article. Our resolution to-day is "That the 85th of the Articles of Association be repealed, and that in lieu thereof the following be henceforth the 85th of such articles:—'85. The directors may, from time to time, of their own authority, pay to the members in proportion to the amounts paid up, or credited as paid up (the very words of the previous article), on the shares held by them respectively, such bonus and such interim dividends as in the judgment of the directors the position of the Corporation justifies.'" We consider, therefore, having, as I told you, looked through the figures this morning, that our position justifies our dividing among you this sum of £245,000 [applause]. We therefore recommend you to pass this resolution, in order to enable us to distribute the amount among you about the middle of August. I beg to move the resolution I have read.

Mr. J. S. Sellon: Gentlemen, I beg to second the resolution which the chairman has so well put before you. He has fully explained to you the reasons which make it desirable that this resolution should be carried, and therefore it is quite unnecessary that I should amplify those reasons. I therefore simply beg to second the resolution, hoping it will be your pleasure to accept it.

Mr. Isaac assumed that the amount proposed to be divided arose from the sale of licenses to other companies, which he held was a reduction of what constituted the property of the Company. He, therefore, suggested that instead of the distribution being as bonus, it should be a return of capital. If they could return the whole of the paid-up capital they would eventually be able to divide their dividends without the use of any capital at all, but if they divided the £245,000 as a bonus the shares would remain at the same relative value. He, therefore, proposed that the money proposed to be distributed as bonus should be distributed as return of capital.

The Chairman said that the motion was hardly in order, as the proposal he had moved was for the repealing of and the substitution of other words in an article of association. He had not asked for their assent to divide any money, but only to alter an article of association.

Mr. Isaac said he might not have put what he desired to bring before them in proper words, but he would move, "That the proposed resolution be amended to this extent, that after the words 'by them respectively,' there should be inserted the words 'such return of capital' instead of the words 'such bonus,'" &c.

Mr. Wm. Abbott: It does not seem to me that any one has risen to second the resolution of the hon. proprietor, and, therefore, I think I form a true

Digitized by Google

estimate of the opinion of this meeting, that they do not quite agree with the resolution he has proposed as an amendment. I must candidly say I do not agree with the proposal of the honourable proprietor, and for this reason he is under a wrong impression in supposing that this Company has parted with any valuable portion of its property through having granted licenses or sold concessions for any particular part of this country or abroad. I should be glad to be corrected by you, Mr. Chairman, if I am wrong in supposing that the sale of these concessions—although we have parted with licenses to develop the Brush system in various parts of this country, and Europe—forms a very valuable adjunct to this Company, seeing that we shall manufacture the whole of the material these subsidiary companies employ. Therefore, these sales give us a very valuable outlet for the particular commodity with which we deal without any increase of capital to this Company. Now, so far as I can understand it, you establish really a goodwill of a going business —a profitable goodwill, which should, therefore, increase the value of the capital. But, in order to still further increase it, it is desirable that you should have, in addition to a large reserve fund which I hope you have created out of the sale of these concessions, a very large capital of your own, which should give you the command of the market in electrical light business. Therefore, I should look with considerable jealousy on the proproposal of the honourable proprietor, that any of the capital already subscribed should be returned to the shareholders for unprofitable employment, when in this Company it is so very profitably employed. It has been the fashion of companies from time to time at periods of great prosperity to reduce their capital. It was done with the Telegraph Construction Company—a favourite company with me—at a time when they made very large sums of money. The directors very wisely said "this is exceptional," and wrote down their plant, machinery, and goodwill, and returned that money to the extent of £8 a share to their proprietors. But it seems to me in this operation which you have engaged in that exactly the reverse has taken place. You have increased the value of your goodwill, and, therefore, in common sense, you cannot possibly write it down. I, therefore, trust you will not be led away by any such proposition. I commend you for proposing to divide £245,000 among the shareholders, presuming that before you arrived at that figure you took care to make ample provision for the future [hear, hear from the chairman]—to write down the patent rights, machinery, and so on, which always deteriorates, but surely you cannot have any justification for writing down a goodwill of a business which seems to me to be steadily on the increase.

Mr. STEWART asked whether the board were justified in allowing a portion of the proprietors to pay the sum of £10 on their shares without giving the same option to all proprietors, a great number of whom had only paid £4 on their shares. If there was no distinct justification for this he should move an amendment.

The CHAIRMAN: May I ask whether you are an original proprietor, because if you are you would know what are the facts of the case—that when this Company was first started, no one believing in the success we have now achieved, was very much inclined to put money into it, and when we issued the prospectus and asked for our capital, we had some difficulty in getting together what we wanted, and we did then invite all proprietors to pay up in full. We not only gave the opportunity but made the request, and urged them to do it, and therefore every proprietor had then the opportunity of paying up his shares in full. But I should like to tell now the whole story. There were some proprietors who, believing in the success of this electric light, did so, and now hold £10 shares. There was one gentleman in particular I remember (I will not mention his name, but I have no doubt he is present) who went to the secretary, and, having bought shares on which £4 had been paid, was anxious to pay a little more than he had done, after we had stopped the further payment. We had the money we wanted, and we said those who have paid £10 up to the present will hold £10 shares, and those who have paid £4, will hold only £4 shares from such and such a date. After that one gentleman went to our late secretary after the shares were at a premium, and wanted to go on paying up so as to make his £4 shares £10 shares. The matter came before the directors, who were obliged to honour the engagement of their secretary so far as it had been made, but we then put a stop to the operation, and no one was allowed to pay up on his £4 share. These are the exact facts of the case. I think that is what you wished to know.

Mr. BROOKSBANK observed that the gentleman who had proposed an amendment was quite out of order, and even the directors, potent as they were, had no power to reduce the capital, which was *ultra vires* He, however, considered that the last shareholder who spoke (Mr. Stewart) had uttered good sense. It was, he contended, a mere accident that made the £10 shares entitled to so much more bonus than those on which £4 had been paid, and he inquired whether it was the intention of the directors that they should continue £10 and £4 paid, or be made all £10. Surely it was a case of great hardship if those who had paid £4 were only to share *pro rata* in the proposed distribution. The directors, however, had only strict justice to administer, and not to take any advantage.

Mr. H. MAUDSLAY asked the amount which had been placed to the credit of the reserve fund of the Company.

The CHAIRMAN: As to that question, before coming into this room, as I told you, we went into certain figures. Our object in doing so was not only to see what amount we could offer you for distribution, but also to see what we had left to represent the capital and assets of the Company, and in doing so we found that there was a very large margin indeed representing the paid-up capital, and what we had in hand, and what we should retain after distributing this £245,000. We did so not so much on your account as on our own, because we said to ourselves we are not going to incur any liability. We are not going to touch the capital of the Company, but only divide the profits, and shall only ask the shareholders to receive among them profits, still retaining the capital of the Company intact, and a large margin beyond it. That is the position in which we are before you to-day. As to what Mr. Brooksbank said as to this being an accidental circumstance, I think it hardly an accidental circumstance whether a man subscribes £10 or £4. It may depend on the accident of how much he has at the moment to put into the company to which he wishes to subscribe; but that is the only accidental part of it. I think it was with great deliberation that gentlemen first subscribed their £10 or £4 when we offered them the option of subscribing the one or the other. I quite agree with Mr. Brooksbank that we wish to do even justice to every one. That is our desire. I should be very sorry to wrong any set of shareholders. One or two gentlemen representing the £4 shares have spoken very nicely and well their notions on the subject, but we have not heard anything from the £10 shareholders. I think that that is because there is no proposition to do injustice to the £10 shareholders, but if we were to give the shareholders who have paid only £4 a larger amount in this distribution than in proportion to the amount they have subscribed, we should have an outcry from the £10 shareholders. We do not wish to have an outcry. We are not going to do what we think, or you think, justice, but what is prescribed by the Articles of Association. He then again read Article 84, particularly calling attention to the wording to show that the profits were to be distributed in proportion to the amounts paid on the shares. Continuing, he said: Those articles were not put together with the view to this state of things, as it is quite clear from the following article that what has happened was not contemplated. We are bound to pay the profits to every man in the proportion that he has subscribed to the capital of the Company. And that really seems common sense on the face of it—that every one shall receive in proportion to what he subscribed, especially when every one had the option at the beginning to subscribe £10 or £4 as he pleased. I will, therefore, put this resolution. The amendment was no amendment whatever, because it was not seconded.

Mr. ISAAC wished it to be understood that he had not suggested that any larger proportion of the profits or return of capital should be given to the £4 shareholders than they were entitled to in proportion to their subscription to the capital of the Company.

The CHAIRMAN: You only did it in an indirect manner [laughter]. Having read the resolution, he added: I may mention that I have a very large amount of proxies, but I am sure that it is not necessary to refer to them. He then asked them to vote on the resolution in the usual manner, and declared it carried with two dissentients.

Mr. BROOKSBANK asked if they were to understand that in future they held only £4 shares. On the face of the document, he held £10 shares with £4 paid up.

The CHAIRMAN: When I said £4 shares I meant £10 shares with £4 paid up.

Mr. BROOKSBANK contended that if the Articles of Association were unjust the Court of Chancery would remedy that defect.

A SHAREHOLDER observed that the chairman was bound by the Articles of Association.

On the motion of Mr. MAUDSLAY, a vote of thanks was passed to the chairman.

The CHAIRMAN, in reply, said: I am very much obliged to you for so kindly proposing this vote, and carrying it with such cordiality. I hope that we shall go on and flourish, as we have done so marvellously up to the present time.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).

A half-yearly general meeting of this Company was held at 38, Old Broad-street, on the 18th inst., under the presidency of Sir D. Gooch, Bart., M.P.

The SECRETARY (Mr. W. Shuter) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, this is a meeting more for the purpose of your asking questions than for receiving any report from the directors. We present no report and accounts, but I will state shortly the work done during the past half year. We have manufactured about 1,000 miles of cable, and laid about 550 miles of the cable we have manufactured in the last year. We have also laid the German Union Company's cable between Emden and Valentia. That was completed in April by the "Scotia." We have repaired the North Sea cable, which is also now completed; and the "Kangaroo" has been twice to the Brazils to carry out cable for the Western and Brazilian Company, and to repair the Brazilian Submarine Company's cable, near Pernambuco. The "Scotia" has now been about two months in the Atlantic repairing the Brest—St. Pierre cable for the Anglo-American Company. She recovered the cable in about 1,940 fathoms of water, and repaired it, and put in 60 miles of new cable. She then began to repair the fault that has for some time existed in the cable near Brest. That she is now engaged in doing. She has recovered the ends and buoyed them, but the weather has been so bad that she has not been able to put in the new piece. We, however, hope that that will be completed soon—as soon as they get two or three days of fine, calm weather. She will then go to the Atlantic again to do some more repairs that are necessary there. It is a great thing to do to lift a cable which has been down twelve years in mid-Atlantic, repair it, put in a new piece, and restore the cable. The cable taken out was in fair condition—in fact, very good condition, considering the length of time it had been down, but there were some traces of defects taking placing at short intervals of the cable from some chemical action at the bottom of the sea. That did not continue far, but it was quite sufficient to create weak points in the cable. We thought it was almost more than we could expect to recover that cable and repair it at such a depth of water after so long a period. We are endeavouring to keep our works going by doing all we can to secure cable work. Having told you practically what we are doing, I am afraid I have nothing further to tell you as to the future. We are, of course, negotiating for work, and I hope we shall be able to continue as we have hitherto done. I shall be glad to answer any question if any gentleman has any to put.

Mr. HEALY: As to the 700 miles you have now of Government contract, is that work to be done in a hurry?

The CHAIRMAN: I do not quite know what you refer to.

Mr. HEALY: I have only heard it, and I asked you the question.

The CHAIRMAN: We have not a Government contract.

Mr. HEALY: But you had one.

The CHAIRMAN: We had one. We have laid a cable of 900 miles in the middle of the half year. There is no resolution to put, and if no other shareholder has any question to ask I must declare the meeting at an end.

A SHAREHOLDER: I think it right that we should propose a vote of

Digitized by Google

thanks to the chairman before we leave. If there is not much to say, the chairman has at all events told us all, with his usual courtesy in the chair.

The motion was seconded, and carried unanimously.

The CHAIRMAN: I am very much obliged to you, gentlemen.

The proceedings then terminated.

THE CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).

The twenty-second ordinary general meeting of the shareholders took place at the Company's offices, No. 61, Old Broad-street, on Wednesday last, Mr. Thomas Hughes, the chairman, presiding.

Mr. JAMES SCOTT (the secretary) read the notice calling the meeting, and the report and accounts were taken as read.

The CHAIRMAN: I will then at once move "That the report and accounts as submitted to the meeting be received and adopted." The shareholders will have seen from the report that the half year has been the most successful that the Company has ever seen since its establishment, which will be, no doubt, as satisfactory to them as it has been to the board [hear, hear]. The traffic receipts—which is the best test—as compared with the traffic receipts of the corresponding half year of 1881, show an increase of £3,000, or very nearly so. With respect to the distribution the shareholders will see that again the board have thought it wise to carry a very considerable sum to the reserve fund. The shareholders who have attended here on other occasions are aware that this has been the policy of the board from the very commencement of the Company, and that the board will not feel themselves in a thoroughly satisfactory position until the reserve fund reaches £50,000 at least. You will be glad to see that that result is being very nearly approached, for the reserve fund now stands at the sum of £47,000. Then, I suppose, the shareholders will concur with the board in thinking that, under the circumstances, the dividend on the ordinary shares should be increased to 8 per cent. [hear, hear]. That is the recommendation that we lay before you for your assent. I do not believe there is any subject upon which I need trouble the shareholders further. They will have seen by the accounts that the expenses are practically the same, in fact some £200 less than in the corresponding period of last year, although the business has increased so largely. With regard to the question of the dispute in the Spanish Government, you will see that everything has been done to bring that to a conclusion which could be done, and we trust the result of the appeal will be at least to put us in a position of getting a return of the funds. After the ordinary business is transacted this meeting will have to be converted into an extraordinary meeting to deal with the question of the auditors. Therefore, without infringing on your time any further I will move "That the report and accounts as submitted to you be received and adopted" [hear, hear].

Mr. ALEXANDER F. LOW: I beg to second that.

Mr. GREENWOOD thought they would recognise their improved position more fully than the chairman in his modesty had been good enough to put it. They should congratulate the board on their successful management, and themselves upon their improved position resulting from such management (hear, hear]. They were in a better position, he thought, he might say certainly, than within his recollection, they had ever been before [hear, hear]. Proprietors would probably put the figures together for themselves, but if not, he could tell them that the earnings of the Company for the half year had amounted to 15 per cent. per annum. They were paying 8 per cent.; they were adding £1,700 to their balance, and £3,950 to reserve, which was equal to another 7 per cent. per annum. It was true that was the best half of the year, but taking the whole of the year they had earned and paid 7 per cent., and they had reserved another 2 per cent. per annum for the half year, which was equal to 1 per cent. for the year. This would make 8 per cent. in the earnings, besides adding to their reserve £7,000—it having stood at £40,000 at the beginning, and £47,000 at the end of the year—which was equal to a thirtieth part of the whole capital of the Company. He thought that could not be said of any other telegraphic company in existence, and they might fairly congratulate themselves on the improved position of affairs. The only thing which struck one as singular in a company in such a flourishing state, and with such a large actual balance in hand, was that it should be burdened with so heavy a charge as 10 per cent. per annum on preference shares. He did not complain of the terms on which these were issued, for he remembered the time when the preference shareholders came to the rescue. But now they were in an improved position, and were practically purchasing another cable out of revenue, he thought the time had arrived, and he had mentioned it to the board, when it would be well to consider whether it would not be advisable to place themselves in a better position in regard to the preference shares. There were three modes for doing that. One scheme would be the issuing of £100,000 of six per cent. preference shares to be given to the holders of the existing ten per cent. shares, yielding them the same income as they now had. The charge on the Company would be the same, but with this difference, that these shares should be convertible into ordinary shares within a limited period, at the optain of the holder, or failing that, at the end of a certain period to be redeemable by the Company at par. That was one scheme. Another might be for every share held by the preference holders they should be entitled to one share in the ordinary capital, and a sum of money which could be taken from the reserve. And a further mode would be to authorise the board to invest some of their surplus revenue in the purchase of some of their preference shares. At times they had been low in the market, but now they were scarcely to be had. It was possible, however, that executors and others might throw their shares on the market, and the board might have authority to purchase them. He could only congratulate the shareholders on the successful position they now found themselves in [hear, hear].

Mr. GRIFFITHS agreed with the last speaker in congratulating the shareholders on the position of the Company, also as to the advisability of dealing with the preference shares. At the same time, whatever plan was adopted must be a question of contract, as no preference shareholder could be compelled to surrender any of his rights.

Mr. NEWTON asked whether there was any prospect of the connection of the West Indian system and the Brazilian, which would increase their traffic? He would also like to know if the board had any further information with respect to the threatened competition at some future period of Mr. Jay Gould? With regard to the issue of capital to take the place of the 10 per cent. preference shares, he did not think it possible to alter the conditions of that issue. The only way to deal with it would be to give the preference holders the option of converting into ordinary shares.

The CHAIRMAN, in reply, said they were told that the Brazilian connection was not likely to be carried out at present. He hoped it would be at some future period as it would be a source of great profit to the Company. With respect to the threatened competition, so far as they had been advised, it had for the present at any rate entirely gone off. As to the 10 per cent. preferences it had been said that they would not be able to purchase the preference shares; but he believed that this will be by far the best way to deal with them. The board would, however, take the matter into consideration, as it would be an advantage to the Company if they could arrange this affair of the preference shares.

Mr. GRIFFITHS remarked that some time since the Master of the Rolls decided that preference shares were a prior mortgage in a company. The company could not get rid of them in the bulk, but every single shareholder must be appealed to.

Mr. NEWTON agreed with Mr. Griffiths, and referred to a case in which every preference holder had to be asked for his signature, otherwise they might have upset the arrangement.

The resolution was then put and carried unanimously.

Dividends on the preference shares of 10 per cent., subject to income-tax, and of 8 per cent., free of income-tax, were next declared.

The retiring director, Mr. A. F. Law, was re-elected, the auditor, Mr. Greenwood, being also re-appointed.

A long discussion then ensued as to the desirability or otherwise of appointing a second auditor, the result being that the meeting by a majority of one decided in favour of a second auditor.

Mr. GREENWOOD then demanded a poll, which was taken forthwith, the result of it being in favour of only one auditor.

The meeting was then made special to pass certain resolutions carrying out the recommendations of the last meeting, that the board would have the power of filling up any casual vacancy in the office of auditor, subject to the notification of the next general meeting. After some discussion it was agreed to let the matter remain as before.

A cordial vote of thanks to the chairman and directors closed the proceedings.

NORTH-EAST COAST EXHIBITION OF NAVAL ARCHITECTURE, MARINE ENGINEERING, FISHERY, LIFE-SAVING, AND COAST-LIGHTING APPLIANCES.

To be opened at TYNEMOUTH on 6th SEPTEMBER, 1882, for not less than Twenty Days.

PATRONS.

His Grace the Duke of NORTHUMBERLAND, Lord Lieutenant of the County of Northumberland; President of the Royal National Lifeboat Institution.

The Most Hon. the Marquess of LONDONDERRY, Lord Lieutenant of the County of Durham.

PRESIDENT.

The Right Hon. the Earl of RAVENSWORTH, President of the Institution of Naval Architects.

VICE-PRESIDENTS.

The Right Hon. EARL PERCY, M.P.

Sir WM. GEO. ARMSTRONG, C.B., President of the Institute of Civil Engineers.

PERCY G. B. WESTMACOTT, Esq., C.E., President of the Institute of Mechanical Engineers.

With others.

Sections.	Presidents.
Naval Architecture	Charles Mitchell, Esq.
Marine Engineering	F. C. Marshall, Esq.
Fisheries	J. M. Ridley, Esq., Chairman of the Tyne Salmon Conservancy.
Life Saving	Commander C. F. W. Johnson, R.N.
Coast Lighting, &c.	Capt. Watson and Capt. F. Smith, Trinity House, Newcastle.
Civil and Sub-Marine Engineering	P. J. Messent, Esq., Engineer to the River Tyne Commissioners, and H. H. Wake, Esq., Engineer to the River Wear Commissioners.

In connection with the Exhibition there will be a LOAN DEPARTMENT, and the committee will be glad to receive exhibits of all objects of marine interest. WORKMEN'S approved MODELS, EXHIBITS of COAL and COAL SHIPPING APPLIANCES will be received. An Exhibition of ELECTRIC and other PATENT LIGHTS will be included.

Diplomas and Medals will be awarded.

Applications for spaces must be made before 1st August.

GEO. RENWICK, Hon. Sec.
SIDNEY OLD, Acting Secretary.

Offices: 21, Collingwood-street, Newcastle-on-Tyne.

ADVERTISER (22), skilled in electrical matters, will GIVE a valuable INVENTION connected with incandescent lighting for a SITUATION as Assistant Electrician.—Address, W., "ELECTRICIAN" Office.

A YOUNG GENTLEMAN, with a good theoretical knowledge of electricity, desires an APPOINTMENT where he would have full opportunity of qualifying himself in all branches of Electrical Engineering.

Apply, with lowest terms, to S. B., 133, Ramsden-road, Balham.

PATENT OFFICE RESEARCHES.—An OXFORD GRADUATE, experienced in ELECTRICAL SUBJECTS and in the Investigation of Scientific Books and Documents, undertakes CONFIDENTIAL RESEARCHES for INVENTORS and others.

Address "X.B.," Office of ELECTRICIAN, 396, Strand.

WANTED, ADDRESSES of CARBON CUTTERS. No. 2,203, "ELECTRICIAN" Office, 396, Strand, W.C.

BOILER EXPLOSIONS ACT, 1882.

NOTICE to POLICE and SANITARY AUTHORITIES and to the USERS of STEAM BOILERS.

The Boiler Explosions Act, 1882 (45 and 46 Vict., c. 22), is now in force.

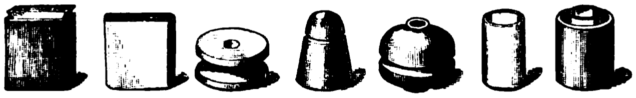
Users of Steam Boilers should at once obtain a copy of the Act in order that they may avoid the penalties attendant on a disregard of its provisions. The clerk of any police, or sanitary, or other local authority, and any user of a steam boiler (other than of a boiler used for domestic purposes) can obtain a copy of the Act gratis by making application by post to the undersigned within ten days from the date of this notice.

Issued by order of the Board of Trade, this 15th day of July, 1882.

THOMAS GRAY,
One of the Assistant Secretaries to the said Board,
7, Whitehall Gardens, S.W.

WANTED at once a thoroughly experienced MECHANICAL DRAUGHTSMAN accustomed to Electrical Work. Salary £2 2s. per week. Apply by letter only, stating qualifications, to Messrs. RANSOME, JOSSELYN, and WOODS, Battersea Foundry, London, S.W. Copies of testimonials only to be sent.

PRIZE MEDAL, PARIS ELECTRICAL EXHIBITION, 1881.



J. STIFF & SONS, Lambeth, LONDON,

MANUFACTURERS OF

POROUS CELLS and PLATES,

BATTERY JARS,

TELEGRAPH INSULATORS,

CHEMICAL APPARATUS, ART STONEWARE,

PLUMBAGC CRUCIBLES, &c.

Contractors to the Post Office and other Departments.

INSULATED ELECTRICAL WIRE, Silk, Cotton, or India-rubber covered. Conductivity guaranteed. German Silver Wires for Resistance. Braided Handle Cord, Silk Cord for Electric Bells, &c.—WILLIAM RICKARD, Derby. London Agent (stock kept), EDWIN HOLLOWAY, 2, Gutter-lane, E.C.

GRIFFITH & CO.

(LATE HARBOROW & CO.,)

ELECTRIC LIGHT ENGINEERS

AND

TELEGRAPH INSTRUMENT MANUFACTURERS

4, QUEEN ANNE'S GATE S.W.

SLIP

Submarine Telegraph Company.—The half-yearly meeting of this company is to be held on the 1st August.

Brazilian Submarine Telegraph Company.—The traffic receipts of this Company for the week ended the 14th inst. amounted to £2,977.

Bahamas.—An American Telephone Company has been making arrangements for the introduction of the telephone into this West Indian colony.

Edison's Indian and Colonial Electric Company.—We are informed that Mr. John Forwood Tafe has been appointed secretary to this company.

Constantinople.—According to a Reuter's telegram, dated Alexandria, July 24, the English authorities have cut the Turkish telegraph line to Constantinople.

United Telephone Company.—The annual meeting of this company has been called for the 1st August. The directors will recommend a dividend of 5 per cent.

Discovery of Zinc Ore.—It is stated that new deposits of zinc ore, similar to those of Franklin and Sterling, have been quite recently discovered in New Jersey, U.S.A.

South African Telegraphs.—The revenue receipts from telegraphs in Cape Colony for May last amounted to £5,302, against £5,867 14s. for the same month of last year, or a decrease of £564 14s.

The "Orient."—This magnificent vessel, belonging to the Orient line of steamships, has been selected to take out a battalion of the Foot Guards for service in Egypt. She is lighted throughout by electric lights.

West India and Panama Telegraph Company.—The estimated receipts of this company for the half-month ended with July 15 were £2,521, against £2,135 in 1881. The March receipts, estimated at £7,345, realised £7,459.

Church Struck by Lightning.—On Tuesday week the church at Kilbirnie, in Scotland, was struck by lightning during a heavy thunderstorm. The stonework of the belfry was loosened and damaged, but nothing more serious occurred.

London Platino Brazilian Telegraph Company.—The revenue of this company for the month of April, 1882, is estimated at £1,595 (Western Brazilian portion £991, Land Lines £604), as against £1,787 for the corresponding period of 1881.

Western and Brazilian Telegraph Company.—The traffic receipts of this Company for the week ending the 14th inst. were £1,828, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

Eastern Extension Telegraph Company.—This company notify that the coupon on their 6 per cent debentures due the 1st of August prox., will be paid on and after that date at the Consolidated Bank, Threadneedle-street, E.C. Coupons must be left three clear days for examination.

Electric Lighting for Kidderminster.—The Town Council of Kidderminster are inviting tenders for lighting the borough for one year. Full particulars can be had of Mr. Arthur Comber, borough engineer, Town Hall, Kidderminster, and tenders are to be sent to him by 10 a.m. on the 9th August.

Post Office Volunteers and the War.—Amongst the volunteers who have been enrolled as a Post Office corps for the Egyptian expedition there are, we understand, several operators from the Central Telegraph station. It may be observed that telegraphists, as such, were not required for this special service.

Accident from Lightning.—At Newton Heath, in Lancashire, on Monday, a lad named Thomas Young was struck by lightning during a thunderstorm, and killed. It appears that he and two other boys were flying a kite at the time, and that all three were struck, though Young only was killed. It is mentioned that his clog was split by the current.

Central and South American Cable.—The India Rubber, Gutta Percha, and Telegraph Works Company have received telegrams announcing the completion of two more sections of the Central and South American Telegraph Company's cables—from Salina Cruz, in Mexico, to Libertad, in San Salvador, and from Libertad to San Juan del Sur, in Nicaragua.

Thunderstorms in Suffolk.—Severe thunderstorms are reported to have passed over the eastern part of Suffolk on Monday. The house of a man named Sudd, at Blaxhall, was struck by lightning and destroyed; and another cottage in a neighbouring parish—Stratford St. Andrew—was also struck. Telegraphic communication was interrupted for several hours.

Induction.—In our notice of Mr. Willoughby Smith's book on this subject we omitted to state that it is published by Messrs. Hayman Bros. and Lilly, of Hatton House, Farringdon-road, E.C. Several correspondents have asked us for details of Mr. Smith's apparatus. We take this opportunity of informing them that they will find full information in the above-mentioned work.

Electric Light for Cleethorpes.—We are informed that the Local Board of Cleethorpes, Lincolnshire, has entered into a three years' contract with the Brush Midland Electric Light and Power Company (Limited) for lighting the public streets with the Brush and Lane-Fox lights, and also that the inhabitants of the town are making arrangements to have the light laid on to the shops and houses.

Proposed Electric and Gas Exhibition.—The gas companies are moving in this matter with some energy. It is stated that the South Metropolitan Gas Company and the Crystal Palace District Gas Company have promised to subscribe £500 and £250 respectively towards a guarantee fund to defray expenses. It is also probable that the Gas Institute will organise a committee to look after gas interests.

The Brush Light on the Tyne.—There are now in use in different works on the Tyne 64 Brush lamps, distributed as follows:—16 at the Palmer Company's Engineering Works, 16 at Messrs. J. Redhead and Co.'s, South Shields; 16 at Messrs. Bell Brothers, Low Walker; and 16 at Messrs. Hawthorn's, St. Peter's. In addition to these we believe that Messrs. A. Leslie and Co., of Hebburn, are about to light their works by 40 of these lamps.

The Electric Light and War.—The *Standard* Alexandria correspondent, telegraphing on the 23rd inst., says:—"The electric light has been established at Fort Komel, and last night illuminated the country outside the walls for miles round, the panoramic effect as the light swept round being very singular and striking." The same correspondent reports that among some eighty-five Europeans and native Christians and Jews who had been brutally tortured and murdered at Tanta were two English telegraphists.

A Hill Struck by Lightning.—During a heavy thunderstorm in the Shetland Islands on Monday, which lasted

Digitized by Google

several hours, a hill three miles from Lerwick was struck by lightning, and huge masses of rock and *débris* were thrown down on the public road which the hill overhangs, filling up the road and valley at the other side, and suspending the traffic. The total weight of fallen rock is estimated at 400 tons, and a gang of thirty men have been working continuously to clear the road. Where the lightning struck the hill there is a deep rut extending down its face.

New Atlantic Cables.—*The Times* states that the persons who have been authorised by Congress to lay new cables between the United States and Europe are Robert Garrett, William F. Burns, and William F. Frick, and not the Baltimore and Ohio Railroad Company. Mr. Robert Garrett is a son of Mr. John W. Garrett, the president of the Baltimore and Ohio Railroad, and is himself a vice-president of the line, with which Mr. Burns is also connected, but it is understood that he and his two associates are acting in this matter on their own account, and not on behalf of the railroad.

Telegraphic Communication with the West Indies.—The telegraphic delegates to the Barbadoes Conference have reported that they deem it unadvisable to attempt by temporarily raising the contribution of the Colony to maintain the present company, and that it will be better to try and secure direct communication with the Northern transatlantic lines. They suggest the appointment of a Board, to sit in London, which shall represent the various West Indian Colonies, to make necessary arrangements, and afterwards to supervise the working of the new line.—*Colonies and India.*

The Telephone and War.—The following passage occurs in Admiral Seymour's despatch to the Admiralty, dated June 12, relating to the disturbance at Alexandria:—"The telephonic communication which I reported in my previous letter had been established between the 'Helicon' and the British Consulate has proved of the utmost value to me since the outbreak of this *émeute*, and inspired the English residents with a certain amount of confidence, as by its means I have been kept constantly aware of the state of affairs generally. In default of this ready means of communication it would have been impossible for some hours to have gained any information from the town, except by special messengers at imminent risk of life."

The Telegraph Train for Egypt.—The *Standard* of Thursday says:—"C Troop Royal Engineer Train, who form the Field Telegraph Corps, consisting of 6 officers, 180 engineers, and 64 horses, will probably be the next troop to leave after the Guards, who are expected to sail on Saturday (to-day). This troop will take out six wire carts with reels, on which the telegraph cable is wound, and two covered waggons, which will form the offices to be affixed at each end of the wire for the receipt and despatch of telegrams. By this means the head-quarters of the general commanding will be in constant communication with the front. There will go out with the telegraph troop a number of experienced telegraphists from the postal department."

The Telephone in Alexandria.—The *Daily News* special correspondent telegraphed from that city on Friday, the 21st inst., as follows:—"A great portion of the Oriental Telephone Company's wires and property was destroyed in the town, and in the present state of affairs it is useless to attempt to put up public lines, but the company's manager and small staff are doing excellent service to the military establishments ashore. Lines have been run up and communication established between the Arsenal, the Raseltin Palace, the Zaptieh Tribunal, the head-quarters of the marines, and to-morrow the General will be in communication with each and all these, and it is impossible to calculate the saving of men and labour this simple instrument affords."

The Edison Light in London.—The Commissioners of Sewers have contracted with the Edison Electric Light Company to light Holborn-viaduct by means of Edison incandescent lamps, for six months, at the same price as gas. It will be remembered that the company have for some little time now been lighting the viaduct with their lamps entirely at their own cost, and as an experiment. We are glad to be able to chronicle their success in obtaining the above contract, and must congratulate Mr. Johnson, manager, and Mr. Hammer, engineer, on the result of their indefatigable energy. We gave a plan of the lighting in the Holborn-viaduct district, with particulars as to the number of lights employed, and other details, in our last volume (Vol. VIII., p. 368).

Electric Light in Engine Works.—The new marine engine works of Messrs. R. and W. Hawthorn, at St. Peter's, Newcastle-on-Tyne, have recently been fitted with the electric light. Altogether there are 16 Brush lamps in use, fourteen of which light the erecting and fitting shops, whilst two do duty in the copper and plumbing shops. The current is supplied by a Brush dynamo machine driven by a pair of direct acting engines designed and constructed by Messrs. Hawthorn, all belting being thus avoided. Gas has now been entirely dispensed with in these works, and the electric lights are reported as giving every satisfaction. The lights have been erected, and the arrangements carried out for the Hammond Electric Light Company by their electrician, Mr. E. J. Jennings.

The Action of the Microphone.—According to recent experiments, reported by a contemporary to have been conducted by Professor Hughes and Mr. de la Rue, and also by Mr. Blyth, it appears that the action of the microphone is now proved to be due, not to variation of surface contact but to the sensitive electric discharge passing between the points. This is precisely the view taken of it by our journal when first the microphone was made public, and the view we have adhered to ever since. We now hear of a "flame microphone," and of speech being transmitted microphonically when directed upon a voltaic arc, as if the idea were quite a new one. The truth is, we suggested experiments in this direction, and predicted the results most explicitly two or three years ago. Everything relating to the explanation of microphonic phenomena has, in fact, turned out just as we asserted it would.

European, American, Canadian, and Asiatic Cable Company.—The prospectus of a new company under the above title has just been issued. It is to have a capital of £1,500,000 in £10 shares. The company have power to establish telegraphic communication between Sable Island and any other point on the Canadian shore and Great Britain, Ireland, and the continent of Europe, and from any point on the Pacific Coast of Canada to Japan and the continent of Asia. A contract has been entered into with Henley's Telegraph Works Company to lay down about 6,120 miles of cables, comprising two complete cables between England and Sable Island, and connections with Canada and the United States, at a cost of £1,443,176. Sir Samuel Canning and Robert Sabine, Esq., are consulting electricians and engineers to the company. The secretary (*pro tem.*) is Mr. S. L. Tomkins, and the offices are at 4, Coleman-street, E.C.

Proposed Exhibition at Tynemouth.—It is proposed to hold an exhibition of naval architecture, marine engineering, fishery, life-saving, and coast-lighting appliances, at

Digitized by Google

Tynemouth, under the title of the "North-East Coast Exhibition," to open on the 6th September next, and continue for at least twenty days. Amongst other things, electric lights of all kinds will be shown. Applications for space are to be made before the 1st August to Mr. S. Old, acting secretary, at 21, Collingwood-street, Newcastle-on-Tyne. We believe that the exhibition is likely to be a success, as already the committee of organisation have had to requisition extra buildings, owing to the numerous demands for space. The guarantee fund has reached £4,250. In connection with this exhibition the Hammond Electric Light Company have, we believe, decided to light the whole of the aquarium, skating rink, and other portions of the building, as well as the two main routes from the railway station to the exhibition. Brush lamps will be used.

Electric Light in the Severn Tunnel.—In our issue of the 15th inst. we stated on what we thought to be good authority that "the Great Western Electric Light and Power Company has received an order from the contractor for the Severn Tunnel for dynamo and lamps for lighting up the tunnel during the progress of the works, and that a dynamo to drive forty lights has been sent down, together with its complement of lamps." Several of our contemporaries made the same statement, doubtless on the same authority. It will be well, therefore, to draw attention to a letter from Mr. Thomas A. Walker, contractor for the Severn Tunnel works, which appeared in the *Western Mail* for 26th July. Mr. Walker expresses surprise at the publication of the information given above, and states that he never heard of the Great Western Electric Light and Power Company until he read the paragraph containing the above news. The editor of the *Western Mail* states that he made the announcement on the authority of Mr. John Parsons, the manager of the Great Western Electric Light and Power Company.

Eastern Telegraph Station at Alexandria.—The *Daily News* correspondent at Alexandria, telegraphing on Friday, 21st July, says:—"The staff of the Eastern Telegraph Company are working actively to open their town office, and, a second cable having been brought into service yesterday, the pressure of business on one line will be taken off to the great relief of all concerned. The Eastern Telegraph building, known as the Maison Canelli, owes its safety to the fact that the Egyptian telegraph being in the same building, when the European clerks left, the native clerks kept working there until the 13th, and a guard of soldiers was told off by Arabi to protect them. The Eastern offices were entered, and all the instruments destroyed by a hammer which I picked up inside broken, and all the lines were cut by some one conversant with the working of telegraphs. The only clerk of the Eastern Telegraph Company, Mr. Ternant, who of his own accord, and contrary to the wishes of the manager, remained in the building during the bombardment, and who was so cruelly murdered, doubtless met his death at the hands of the same ruffians employed by Arabi to cut the wires."

Problem of the Wires.—Mr. H. R. Meyer, of Liverpool, has given in a little pamphlet a "solution of the problem of the wires." He points out that the applications of electricity increase so fast to the multiplication of wires overhead, that the progress of the near future will necessitate the adoption of other than overhead wires. There are some scientific mistakes in this pamphlet, such for example as "that as electricity appears to travel on the surface of a conductor, the more surface is provided the less friction, or, as it is technically called, 'resistance,' and consequent loss of power takes place." In dynamic electricity, it is sectional area and not surface that decreases or increases resistance. Such mistakes, however, have little to do with the plan suggested, viz., to have grooved slabs of earthenware, cement, glass, or other suitable material, which can be laid end to end and the naked wires placed in the grooves, asphalte being freely poured over to act as an insulator. Such slabs could be placed one above the other or side by side in such a manner as to cause little trouble in getting at the wires if required, but it is supposed that the method would be so efficacious as to require little or no trouble after once laid.

Indo-European Telegraph Department.—In a resolution of the Government of India, reviewing the administration report of the Indo-European Telegraph Department for 1880-81, it is stated that the receipts amounted to £88,474 10s. 10d., showing an increase of £7,330 5s. 11d. over those of the previous year, most of the increase being due to increased receipts from the common purse arrangement. The expenditure of the year was £73,113 2s. 10d. being somewhat higher than the normal expenditure of the previous year, owing to increased cost of repairs. The net balance of the year's revenue over working expenses amounted to £15,361 10s.; but this does not include the earnings of the "Patrick Stewart" for services rendered to other departments, amounting to £1,078 6s., and the value of the "Amberwitch" (£4,000) transferred to the Marine Department. Including these items, the net revenue is increased to £20,439 16s., representing a profit of 1·77 per cent. on the capital outlay. Considerable damage was done to the lines in Persia by the storms during the winter, which were exceptionally severe, and the cost of repairs has been consequently somewhat heavier than usual; but, on the other hand, the wilful damage done to the lines was only of a trivial nature. The general results of the year's operations are declared to be very satisfactory, so far as the working of the telegraph service and the efficiency of the lines are concerned, and the Government of India concurs in the commendations by the Director-in-Chief of the staff, through whose exertions such good results have been obtained. But the financial condition of the administration requires careful consideration. The Government of India notes with approval that efforts are being made to increase the traffic, and it may be noted that some reductions have been made in the cost of working since the report under review was written. The total revenue is the largest that has been earned since the alternative route *viâ* Suez was completed, and there seems to be a fair prospect of the revenue increasing; but as yet it does not yield an adequate return on the capital invested, and endeavours must not be relaxed to secure such a diminution of working expenses as shall, without risking the efficiency of the service, leave a fair balance for interest on the capital invested. —*Homeward Mail.*

Why the Electric Light Goes Out.—Recently we gave the reasons stated by Messrs. Siemens to account for the failure of their lamps during the period for which they lighted their district of the City, viz., April, 1881, to March, 1882. We now give similar information from the report of Mr. Haywood to the Commissioners of Sewers relating to the Brush Company. The reasons given by this company for the failure of their lamps are as follow:—"Lace of driving band broke," "switched out maliciously," "defect in carbon," "top carbon fell down from holder," "stop valve broke," "inequality of carbons fitted," "rod of lamp stopped by a little dirt," "nut connected with governor of steam engine broke," "through carbons having burnt out owing to extra burning in the day time on

Digitized by Google

account of fog," "carbon rods carelessly cleaned by lamp trimmers," "put out by heavy gale of wind blowing," &c. This company in several cases question the correctness of the police return as to the length of time for which particular lamps were defective. The number of lamps reported as defective during the year in the Brush Company's district was 660, and the total number of hours for which they were defective was 3,142h. 25min. One hundred and eighty-nine lamps were reported to have gone out owing to defective machinery, 385 owing to defective cables, 24 owing to defective carbons, and 62 defects are classed as miscellaneous. Thus, the aggregate failures of the Brush lamps amounted to 3,142 hours of a single lamp, or about 2·21 per cent. of the entire lighting of their district during the twelve months, whilst in Messrs. Siemens's district the aggregate failures amounted to about 832 hours of a single lamp or 0·57 per cent. only. The number of hours for which the lamps in both districts were assumed to be alight was 4,300 hours, which gives for the Brush Company, with 33 lamps, an assumed total lighting of 141,900 hours of a single lamp, and for Messrs. Siemens, with 34 lamps, a total lighting of a single lamp of 146,200 hours. Speaking of these failures, Mr. Haywood says in his report: "It may be said broadly that in district No. 1 (Brush) a defect of longer or shorter duration occurred in something less than two lamps nightly out of the 33 lamps lighted, and that in district No. 3 (Siemens) a defect occurred in something like one nightly out of the 34 lamps lighted. It must, however, be noted that at an early stage of the experiment a continued series of defects occurred in the Brush system, owing to defective insulation being discovered in a cable, and a new cable had to be laid to rectify this. In Siemens's district defects also occurred in a portion of the system through damage caused by a barge to the conducting cable beneath London Bridge. Apart from these prolonged defects at the outset, the principal failures appear to be attributed by the contractors to defects in the carbons, and to other causes of a character which are likely to be considerably diminished in number as the manufactures improve and experience is gained. The total number of gas lamps in the City of London is 3,225. The number of defective lights observed by the police during the year 1881 was 2,509. The number during 1881 was much larger than usual, and was attributable to the long-continued and severe frosts."

The Proposed New Cable Company.—The following letter referring to the prospectus of the European, American, Canadian, and Asiatic Cable Company appeared in *The Times* of the 26th inst. over the signature of Mr. H. Weaver, managing director of the Anglo-American Telegraph Company. Mr. Weaver writes:—"Sir: I beg permission to call attention to some omissions and errors in the prospectus of the above company. 1. The Anglo-American is the only company which has abandoned any of its Atlantic cables, and the cables so abandoned have been replaced out of revenue. 2. Instead of the five cables mentioned in the table of capital and cables of the existing companies, there are eight cables with which the new company will have to reckon, the two new cables of the American Telegraph and Cable Company which were opened for traffic on the 15th of May last being altogether omitted. 3. An important feature of the new company is stated as follows: 'Instead of pursuing the vacillating policy hitherto in vogue of tentative reductions with alternating augmentations, a tariff of 9d. per word will be adopted.' The promoters take credit for the whole 9d. per word without deducting the payments to be made to the Postmaster-General and to the American and Canadian companies for the use of the connecting land lines on both sides of the Atlantic. These payments, according to my experience, will amount to 2d. per word. 4. In computing the 'entire working capacity of the proposed two cables'—namely, 10,000,000 words per annum, upon which the financial results are based—each cable will have to carry 16,600 words per day, and as the maximum number of hours during which the cables would be employed is about sixteen, I have no hesitation in saying that the alleged 'entire working capacity' is overstated by at least 50 per cent. 5. The calculations of revenue based on such a foundation are, of course, hypothetical, and as I am in possession of actual statistics bearing directly upon the point it will be useful to state them. From the 1st of June to the end of September, 1880, the tariff of the Anglo-American Company was 6d. per word. The greatest number of words transmitted over the cables in any one month was 1,100,000, or say 13,000,000 per annum. In order, however, to give the promoter's calculations the full benefit of any possible increase I will take as the basis of calculation 16,000,000 words per annum as the total traffic to be transmitted by and divided between the four existing companies and the new company. 6. It cannot seriously be contemplated that the existing companies would stand quietly by and allow the new company to monopolise the entire traffic. The total number of all cables would be ten, of which I will assume the new company to possess two, and that these lines might obtain and carry one-fifth, or its due numerical proportion of the whole traffic. One-fifth of 16,000,000 words would be 3,200,000, which, at 9d. a word, would yield £120,000. Deduct—paid-outs to other administrations, say, 2d. per word, £26,000; renewal fund as per prospectus (quite inadequate for two cables), £45,000; working expenses, as per prospectus, £80,000—total, £115,000, showing a loss of £31,000 per annum, instead of the estimated profit of 17 per cent. on the new company's capital. Having regard to the above figures, it is needless to discuss 'the mutual feature,' since its introduction will scarcely make up for the unsoundness of the other financial features of the scheme." In *The Times* of the following day two letters appeared in answer to the above. One was from Mr. W. C. Jarvis, of the Home, Foreign, and Colonial Electric Light and Power Share Trust Company, 88, Bishopsgate-street, E.C., stating that with regard to paragraph 3 of Mr. Weaver's letter the payments for the use of the land lines have been carefully calculated to be 1½d., and not 2d., as stated by Mr. Weaver. The other letter was from Mr. S. L. Tomkins, secretary (*pro tem.*) to the proposed new cable company. This gentleman criticises Mr. Weaver's letter paragraph by paragraph. The sum of his contentions are, taking each paragraph in order, that—1. Three cables have been abandoned by the Anglo Company, and that the French cable has not been working for two months. 2. That this reduces the number of working cables to four, excluding Jay Gould's. 3. That Mr. Weaver's estimate of 2d. per word for payments for land lines, &c., is too high. 4. That a cable's carrying capacity is greater now than it was, owing to scientific advances, and that a cable may be worked twenty-four hours instead of sixteen. 5. That a permanent low rate and natural development of trade will cause a large increase in the total traffic of Atlantic cables. 6. That Mr. Weaver's calculations, being founded on the fact of there being ten cables and the new company's obtaining only one-fifth of the traffic are fallacious. That a lowering of rates by the older companies would mean a loss to them. That the Anglo Company themselves "reserved £75,000 for four old cables on a capital of £7,000,000. Of this sum £11,000 was actually expended during the year for repairs of cables."

THE CRYSTAL PALACE EXHIBITION.

Post Office Exhibits.

(CONTINUED FROM PAGE 230.)

We have already alluded to the Wheatstone automatic system of telegraphy, by means of which despatches are transmitted at rates ranging from 50 to 250 words a minute. Formerly the Morse signs were produced by hand keying alone, but with a view to meet the pressure over certain routes, and to diminsh the number of wires, this fast method was devised. To obtain automatic transmission a slip of paper is perforated in such a way that as it runs through the "transmitter," represented on the right of Fig. 18, corresponding Morse characters appear in ink upon a band of paper at the distant station.

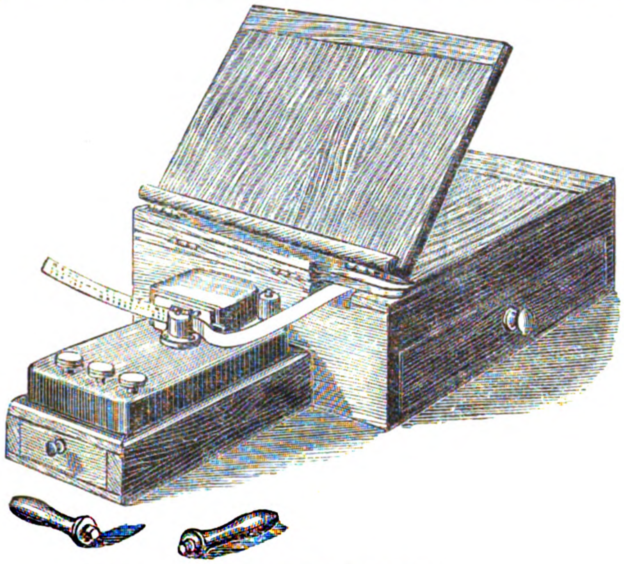

FIG. 16.—The Wheatstone Perforator.

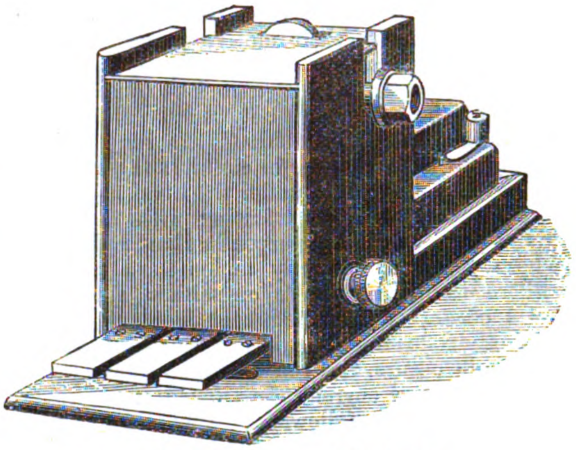

FIG. 17.—Pneumatic Perforator.

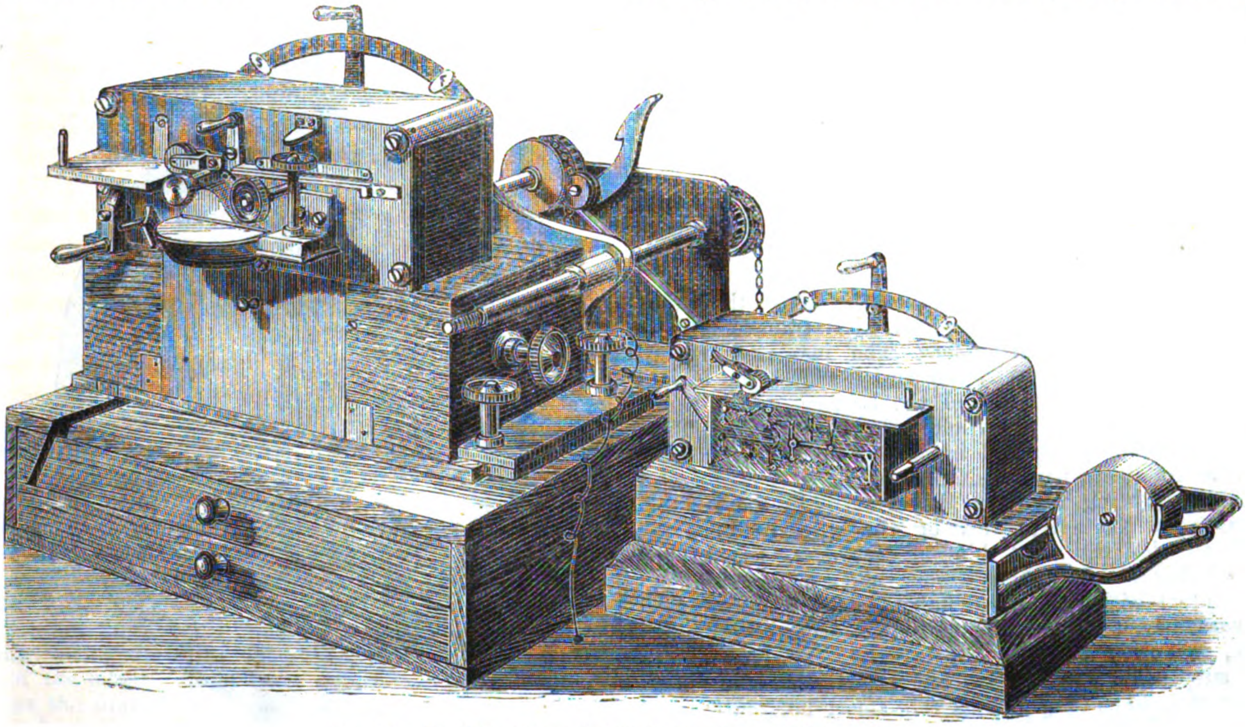

FIG. 18.—The Wheatstone Automatic Receiver and Transmitter.

The "perforator," Fig. 16, is purely a mechanical arrangement. It has three metallic discs, which, when depressed singly, cause levers to force the points of small rods through the paper slip, and to produce one, three, or four holes, as may be required. The disc on the left punches holes representing a dot, and that on the right the holes for a dash. The centre disc makes small spacing or guiding holes in the middle of the slip, and is struck once between letters and twice between words. A moderate pressure of fingers on either disc suffices to pierce the tape; but in practice iron mallets, as seen below the perforator, are used to give a stronger impetus to the blow. Each mallet is furnished with an india rubber pad at the end, which strikes the discs. The so-called dot or dash punctures consist of two round perforations separated by one or two of the central spacing holes—a pair of vertical holes representing the dot, a pair of oblique holes representing a dash. The punching rods are withdrawn from the holes in the paper by the return of compressed spiral springs to their normal tension of inactivity, and the paper is hitched forward at every blow by a small wheel having ten spokes on its periphery, and moving through $\frac{1}{10}$ or $\frac{2}{10}$ of its circumference. The space between the spokes is equal to that between the guiding holes of the slip, and as a click operates upon the wheel, so the spokes of the latter gear into the guiding holes of the paper, and drive it onward.

An expert operator is able to prepare the perforated slips in this way at a rate of forty words per minute for some

Digitized by Google

time; but it must be obvious to our readers that the labour of wielding the iron mallets described above is considerable when the circuit is a busy one; hence, in order to save human energy, pneumatic pressure has been brought into requisition. Fig. 17 represents a frame containing an ordinary perforator, but in this case a gentle pressure on either of the three keys enables compressed air to force a piston down on the respective perforator discs beneath, and to prepare one or more slips as required. The number of punchers engaged in supplying one transmitter with slips depends upon the speed of signalling, and the speed of signalling, of course, depends upon the business to be done, as well as the condition and construction of the circuit.

The electrical "transmitter" and "receiver" are represented in Fig. 18, the former on the right, and the latter on the left side. They derive their motive power from heavy weights, which are wound up occasionally by hand. The speed of these instruments is regulated by the sliding arm seen at the top of the instrument between the stops lettered F and S, meaning "fast" and "slow." To send a message from a transmitter to a receiver in circuit, the punched slip is drawn forward by clockwork under the little roller which revolves over an aperture communicating with the interior. Under this roller are two perpendicular rods, almost parallel, whose points are directly under those portions of the slip where the larger holes on either side of the guiding holes occur. When the paper is blank, then the points of these rods simply press upwards against it; but, when a hole occurs, the rod instantly darts through, and causes a momentary current of a particular sign to circulate. This first current is followed by a momentary current of the opposite sign brought into action by the other rod. In the case of a dot, the interval between the two currents is short, while the duration of interval for a dash is double the length. The electro-magnetic effect of the first current causes a small inking wheel in the receiver to touch the moving paper tape there, and thus begins to make an ink line, which is afterwards broken by the succeeding short reverse current. The length of mark on the tape of the receiving end therefore depends upon the interval between the reverse currents, brought about by the holes in the transmitting slip.

THE BURGIN ARC LAMP.

The Bürgin electric lamp consists of a square box containing the regulator mechanism, of a tube guide for the upper movable carbon holder, and of the lantern where the arc between the two points of the carbon is formed.

Fig. 1 represents the whole length of the lamp, the tube being broken in order to insert a horizontal transverse section of the regulator mechanism. The insulated upper carbon holder is suspended by the cord *f*, whilst the lower carbon is fixed in the lower part of the lantern, and is thus in metallic contact with the whole body of the lamp. The regulator mechanism contained in the box up above is composed of the following parts:—N S horse shoe electro-magnet, capable of being regulated horizontally by the screws V V. One of the extremities of the wire bobbins is attached to the insulated binding screw *e*, the other extremity being attached to the copper tube serving as guide, and in contact with the carbon holder. The armature *i* is placed vertically, and forming one side of a movable parallelogram, the other side of which is fixed. The two other sides or suspension links *k l* are but slightly inclined from the horizontal, so as to give by a very small horizontal displacement as slight a vertical movement as possible to the armature. A very fine copper wire of high resistance envelopes the body of the armature, so that the magnetic poles produced are the same as the neighbouring poles of the electro-magnet. This fine wire is attached, on the one hand to the binding screw *e*, and on the other to the body of the lamp. The armature is bored throughout its length, and carries at the top the little pulley *b*. A support, *p*, is fixed against the armature. It holds the spindle *q*, upon which is keyed the flywheel R and the grooved pulleys *x* and *a*. The

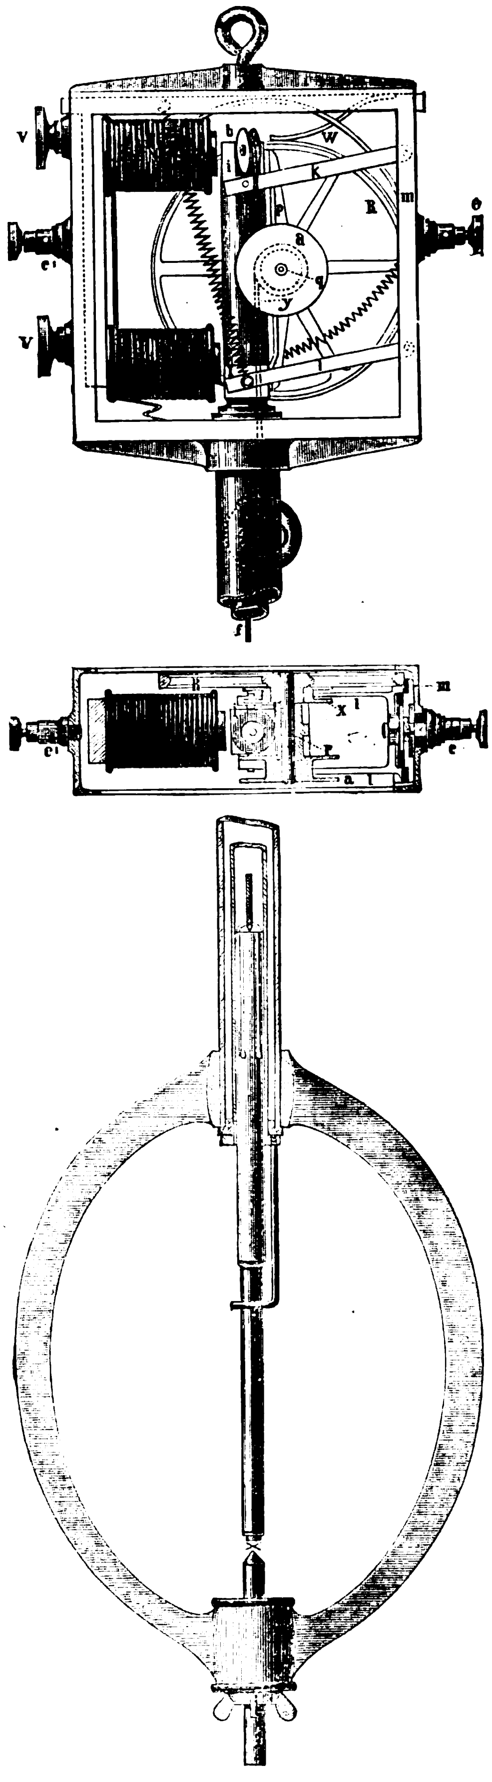

FIG. 1.—Regulating Mechanism and Holder of Bürgin Arc Lamp.

whole of this mechanism participates in the movement of the armature.

Digitized by Google

The small cord, *f*, supports the upper carbon holder. This cord rises straight through the centre of the armature, passes over the pulley *b*, and round and round the drum *a*. A second cord, *y*, is rolled round the drum *x*. A copper ring is suspended to its other extremity, by means of which the upper carbon may be hauled up. A break, W, is in contact with the flywheel R; *e* is an insulated binding screw, receiving positive current. The negative binding screw *e'* is in metallic contact with the body of the lamp.

When the electric current enters the lamp by the binding screw *e*, it divides into two parallel currents, one of which flows round the bobbins of the electro-magnet, and on to the carbons, and the other through the fine wire round the armature. The intensity of the two currents is in inverse proportion to the resistance of their respective circuits, which is several hundred ohms for the fine wire, and one to three ohms for the electric arc. The electro magnet attracts the armature and raises it, at the same time presses the flywheel R against the spring W. From this moment the spindle *q* cannot turn, neither can the cord *f* unroll. The upper carbon holder which is suspended is forced to follow the upward movement of the armature until the reaction of the spring *w* causes an equilibrium to be maintained. In this manner the luminous arc is formed.

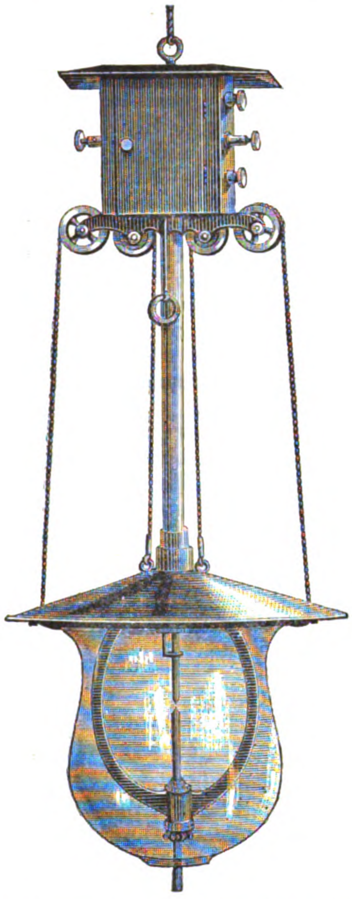

FIG. 2.—Bürgin Arc Lamp for Outdoor Use.

In consequence of the combustion of the two points of the carbons, the length of the arc, and at the same time its resistance, is increased little by little. The secondary current passing round the armature as well as the electro-magnetism of the latter consequently increase until the repulsion between the similar poles allows the armature to drop a little, the flywheel then becomes disengaged from the action of the spring break, and the upper carbon holder descends by its own weight. The secondary current round the armature and its magnetism diminish immediately, and the whole system enters into a state of fluctuating equilibrium between the combined action of the magnetic attraction and of the spring *w* on the one hand, and that of the weight of the carbon holder on the other. A continued but slow feed of the upper carbon ensues, so that the length of the arc remains constant. Each lamp regulates itself according to the length of its own arc, therefore several may be placed in series on the same circuit. The lamps are regulated by means of the screws V V, by which the electro-magnet is placed nearer to or farther from the armature, just as it is deemed advisable to lengthen or shorten the arc. The magnetic attraction and repulsion depend directly upon the intensity of the primary and secondary currents, owing to the mode of suspending the armature, which ensures almost a constant distance between the poles of the electro-magnet. The inconvenience attached to the ordinary mode of suspension, viz., that the magnetic attraction varies in proportion to the square of the interpolar distance, is here completely eliminated.

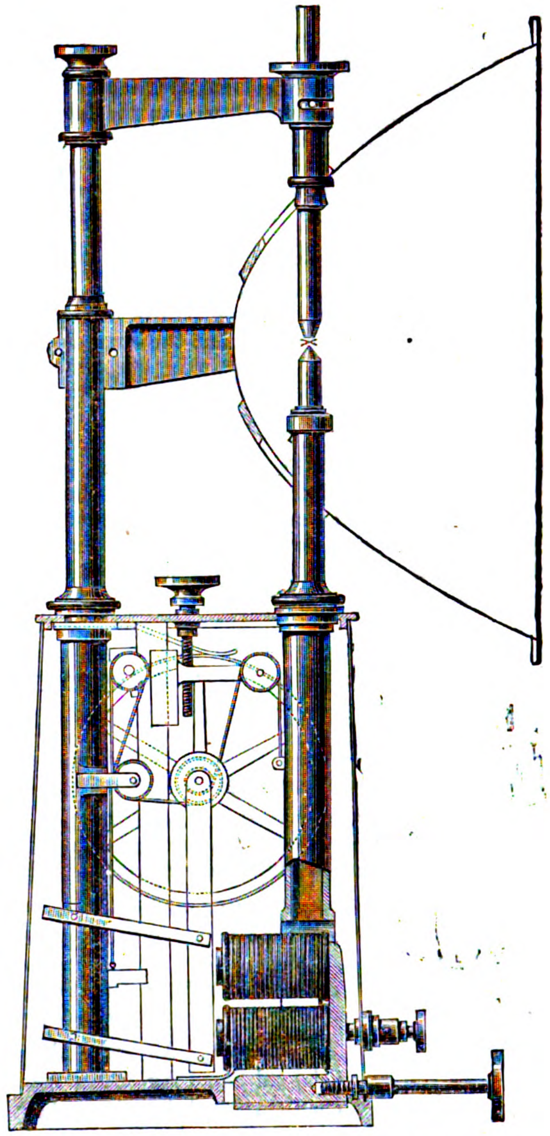

FIG. 3.—Bürgin Arc Lamp fitted with Parabolic Reflector.

Thus may be seen the possibility of obtaining with a regulator mechanism of great simplicity a lamp which will maintain a steady arc. Fig. 1 shows the arc in a position corresponding to the lower extremity of its course. The total length of this course, that is the distance between the highest and lowest points, is equal to a third of the length of the carbons. This is the length which the negative carbon will diminish in a given period. The upper positive carbon diminishes double this length in the same time; it therefore loses two-thirds of its length, and as at the same time it is forced to follow the lower carbon, its course is equal to its total length. The upper carbon holder stops against the wire guide at the instant when the lower carbon should be renewed; but the remainder of the upper carbon, being just

Digitized by Google

one-third of the total length, is sufficient for replenishing for a complete period the lower carbon holder. The upper carbon holder receives then a complete carbon, and the lamp is ready for use. The period is eight hours when carbons 50cm. × 13mm. are used, and the current is 20 amperes. This current uses 6cm. of carbon per hour, of which four are used by the upper and two by the lower carbons, *i.e.*, in eight hours, 32 + 16 = 48cm. The remaining 2cm. of carbon can be thrown away.

Fig. 2 represents the one form of this lamp constructed for long carbons, to burn for periods of 12 to 14 hours, the length of a winter night. This lamp is intended to burn in the open air; it is, therefore, furnished with an overhanging top protector, a conical reflector, throwing downwards the light which would otherwise be lost, and a glass bell protecting the arc from the wind.

Fig. 3 represents the lamp with fixed focus, for scientific purposes, and projecting the light to a distance by parabolic reflectors, as well as for projection with obscure chamber. In the last case it has been employed in the laboratories of several European universities.

For projecting the light to a distance it is particularly appropriate to lighthouses, and has been employed on river steamers, &c. The regulator mechanism is the same as that employed in the suspended lamps, but the secondary current round the armature is useless in this lamp, as these lamps generally work one in a single circuit. The reason which causes the carbon points to approach each other when the arc is too long is that the current, and therefore the magnetism of the electro-magnets, diminishes and allows the armature with the flywheel to descend. The lower negative carbon is suspended to a drum half the diameter of that of the upper carbon holder. When the latter, consuming twice as fast, descends by its own weight, it raises the negative carbon half the distance which it falls itself; in this way the focus always remains at the same height.

The same lamp is also constructed with the upper carbon holder fixed in cases where a pedestal lamp is preferred to a suspended lamp.

ABSTRACT OF PAPER ON THE DETERMINATION OF CHEMICAL AFFINITY IN TERMS OF ELECTROMOTIVE FORCE.

Part VI.

On the Relations between the E.M.F.'s Developed in Cells Constructed like Daniell's Cell, but Containing Different Metals, and the Chemical Affinities involved in their Action.

BY C. R. ALDER WRIGHT, D.SC., F.R.S.

Numerous cells have been examined, containing the following combinations:—

I. .... Cd | $Cd SO_4$ | $Cu SO_4$ | Cu.
II. .... Zn | $Zn SO_4$ | $Cd SO_4$ | Cd.
III. .... Zn | $Zn SO_4$ | $Ag_2 SO_4$ | Ag.
IV. .... Cd | $Cd SO_4$ | $Ag_2 SO_4$ | Ag.
V. .... Cu | $Cu SO_4$ | $Ag_2 SO_4$ | Ag.

In all cases the two sulphate solutions employed were of equal molecular strengths, the strengths varying from MSO_4, SOH_2O to MSO_4, 1250 H_2O in the case of combination No. I.; and from MSO_4, 25 H_2O to MSO_4, 1250 H_2O with No. II.; and being MSO_4, 2390 H_2O in the case of the other three combinations. (Cold saturated silver sulphate solution.)

The effect of a given alteration in the character of either the zinc or copper plates when opposed to cadmium (cases I. and II.), was found to be practically indentical with that of the same alterations in the case of a Daniell cell, or combination

Zn | $Zn SO_4$ | $Cu SO_4$ | Cu.

Thus, the average effect of substituting amalgamated copper for freely-deposited electro-copper was to depress the E.M.F. by ·001 volt in each instance, and similarly in other cases. On the other hand, whilst the effect of a given alteration in the character of the cadmium plate was numerically sensibly the same, whether the cadmium were opposed to zinc or copper, yet the sign of the alteration was opposite in the two cases.

Effect of substituting for bright cadmium.	Cadmium opposed to zinc. Volts.	Cadmium opposed to copper. Volts.
Electro cadmium	− ·0005	+ ·0040
Amalgamated cadmium (fluid)...	+ ·043	− ·0415
Ditto do. (solid and crystalline)	+ ·016	− ·015

the + sign meaning increase in E.M.F., and the − sign depression thereof.

Similarly, the effect of a given alteration in the nature of the plate opposed to silver in cases III., IV., and V., was sensibly the same as that produced by the same alteration in any of the other cases; thus, substituting electro-cadmium for bright cadmium in combination IV. increased the E.M.F. by ·0040 volt, and similarly in the other cases. The effect of a given alteration in the nature of the silver plate was, in the same way, practically independent of the nature of the opposed metal.

Effect of substituting for bright silver.	Silver opposed to zinc. Volts.	Silver opposed to cadmium. Volts.	Silver opposed to copper. Volts.
Electro-silver (crystalline)..	+ ·008 ...	+ ·009 ...	+ ·0075
Amalgamated silver (fluid).	+ ·099 ...	+ ·101 ...	+ ·1025
Ditto do. (solid crystalline).	+ ·021 ...	— ...	—

It was, however, noticed that oxidation by dissolved air of zinc and copper plates took place much more rapidly when these metals were used in combinations III. and IV. (opposed to silver) than when opposed to one another in a Daniell cell, the fluids surrounding the oxidisable metals being the same in each case.

The following table gives the average values of the E.M.F.'s of the principal combinations examined, the E.M.F. of combinations I. and II. being sensibly independent of the strengths of the solutions used, provided both are of equal molecular strength:—

Combination I.	
Electro-copper, electro-cadmium	·7525
Electro-copper, bright cadmium	·7485
Amalgamated copper, electro-cadmium ...	·7515
Amalgamated copper, bright cadmium......	·7475
Combination II.	
Amalgamated zinc, electro-cadmium.........	·3595
Amalgamated zinc, bright cadmium	·364
Combination III.	
Amalgamated zinc, bright silver	1·528
Amalgamated zinc, electro-silver...............	1·536
Amalgamated zinc, amalgamated silver (liquid)	1·627
Combination IV.	
Bright cadmium, bright silver	1·1675
Bright cadmium, electro-silver..................	1·1765
Bright cadmium, amalgamated silver (liquid)	1·2685
Electro-cadmium, bright silver	1·1715
Electro-cadmium, electro-silver	1·1805
Electro-cadmium, amalgamated silver (liquid)	1·2725
Combination V.	
Electro-copper, bright silver	·416
Electro-copper, electro-silver	·4235
Electro-copper, amalgamated silver (liquid)	·5185
Amalgamated copper, bright silver............	·4165
Amalgamated copper, electro-silver	·424
Amalgamated copper, amalgamated silver (liquid)	·519

These values, and those quoted in Part V., show that Volta's "law of summation of E.M.F.'s" sensibly holds true in all the cases examined. Thus, the E.M.F.'s of the combinations amalgamated-zinc—bright cadmium, and bright cadmium—electro-copper are respectively ·3640 and ·7485 volts, giving as sum 1·1125 volts; whilst the average E.M.F.

Digitized by Google

of the combination amalgamated zinc—electro-copper was found to be 1·114 volts; and similarly in all the other cases, the average deviation from equality being less than the probable error of the experiments.

On comparing these values with those deducible from Julius Thomsen's thermo-chemical data, a marked discrepancy is noticed between the combinations of form I. and II. and those of III., IV., and V. With the former cells the observed E.M.F. always sensibly accords with that deduced from the thermo-chemical data; with the latter it uniformly falls short by an amount between 0·3 and 0·4 volt. In order to compare the values for the cells containing amalgamated cadmium and silver plates, the heats of solution in mercury of the crystalline metals (precipitated respectively by zinc from the sulphate and by copper from the nitrate) were carefully determined by means of the calorimeter. Using the values thus obtained together with Thomsen's to calculate the heat of formation of cadmium and silver sulphates from the metal, not in the free states, but dissolved in mercury, the following values are finally arrived at:—

	E.M.F. calculated from thermo-chemical data.	Observed E.M.F.	Difference. Volt.
Combination I.			
Cadmium not amalgamated...	·740 + *x* ...	·7475 to ·7525 ...	less than ·02
Do. amalgamated	·727 + *x* ...	·706 to ·707 ...	less than ·02
Combination II.			
Cadmium not amalgamated...	·365 ...	·3595 to ·364 ...	less than ·03
Do. amalgamated	·378 ...	·407 ...	less than ·03
Combination III.			
Silver not amalgamated	1·890 ...	1·528 to 1·536 ...	about ·36
Do. amalgamated	1·981 ...	1·627 ...	about ·36
Combination IV.			
Silver not amalgamated	1·524 ...	1·1675 to 1·1805 ...	about ·35
Do. amalgamated	1·615 ...	1·2685 to 1·2725 ...	about ·34
Combination V.			
Silver not amalgamated	·784 ...	·416 to ·424 ...	about ·36
Do. amalgamated	·875 ...	·5185 to ·519 ...	about ·36

where x is a small + quantity depending on the molecular condition of the copper deposited. A number of experiments were also made on the effect of variations in current density on the E.M.F.'s of the various combinations, with the result of finding that all behave like a normal Daniell cell, the maximum E.M.F. being obtained either when no current at all passes, or when its density does not exceeed a few micro-amperes per square centimetre of plate surface, and the rate of fall in E.M.F. as the current density increases being a gradually retarding one; the actual diminution in E.M.F. for only moderately strong currents being upwards of 0·1 volt. As with the Daniell cell, this is due to peculiar actions taking place at each plate-surface, as well as to the formation of films of liquid of different densities surrounding the plates. The action of this kind taking place at the surface of the plate on which metal is deposited usually exceeds considerably that taking place at the surface of the other plate.

CORRESPONDENCE.

DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am obliged by the letters from correspondents, which appear under the above heading, in your issue of last Saturday; but, if I may again trespass on your valuable space, I should like to state that the engine is by one of our very best makers, quite new, and fitted with patent variable automatic governor expansion gear, which works exceedingly well. She is running well within her power, and could, without doubt, do three or four times the amount of work. I state this, as all your correspondents appear to think the fault may have been with the engine. I also took particular care that the lamps were perfectly free to work, and not out of adjustment in any way. The most likely cause appears to be that suggested by Mr. W. B. Sayers—viz., "That the magnetic system is in a state of unstable equilibrium," due to the "magnetic coupling" (if I may use such a phrase) of the two sets of field magnets. With reference to the letter of "Accumulator," I may mention that I have tried the machines and lamps coupled up in one circuit, but found this would not do, as the lamps are not provided with shunt coils, being only intended to work singly. A slight error of the compositor in my first letter to you may have caused some doubt as to the exact arrangement. The word "plates" in the fifth line should read "plate."—Yours, &c.,

WONDERER.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If Mr. Johnstone cannot see what the real point at issue is, and what the preliminary points to be settled are as I see them, it is a waste of time for us to argue the matter together any longer in your pages.

I maintain that the point at issue is that raised by Mr. Johnstone himself, "Is electricity matter?" and I have proved a *non sequitur* to his deductions from his experimental facts, which latter I have neither admitted nor disputed.

The preliminary work may take several channels of investigation, Mr. Johnstone's dictatorial statements to the contrary notwithstanding; and I would sit and cogitate on the phenomenon of the *induction coil* until it seemed to point to a *material agency*, rather than *assume* such an agency, and make an experiment to prove it.

Surely such a question as the *transmutation of forces* need not be raised. I will not insinuate that Mr. Johnstone is ignorant of the action that takes place in a telephone circuit, though he has set me a different example. Force is transmutable, therefore Mr. J's "fundamental question" is answered.

In a small treatise by Sir W. Snow Harris, pages 74-75, I find the investigation of the Leyden jar by Watson, Smeaton, and their contemporaries recorded, and the following passage occurs:—

"... a succession of sparks will be observed to pass into the jar; these will become gradually weaker when the jar is fully charged."

The cessation of a current under those conditions, therefore, is *not* a discovery of Mr. Johnstone's.
